Affine Projection Algorithm (APA)

Ok, we considered normalized LMS algorithm. LMS, we discussed is convergence, you know derivation, convergence, approximately convergence that is it acts like LMS algorithm actually with μ time varying μ with a μ which is different now μ by tracer and so, that effective μ will have upper bound for convergence is 2μ should be greater than 2 less than 2 greater than 0 all these were discussed. I also showed that if the input is highly correlated then that LMS algorithm requires many iterations to converge, but if the input is white then they convert ideally in the absence of noise just in 2 steps, but for general input which has lot of correlation in highly correlated input LMS algorithm suffers from poorer convergence ok. So, a better alternative here is a generalization of the LMS algorithm called Affine Projection APA. Again, here we will assume all the real case no complex data and though all this can be extended to complex case also, but we will not consider here in this course and also to start with we will not assume any noise. So, we remember what we had in this is NLMS if we had just 2 coefficients w_0 cap and w_1 cap and there is no noise.

So, what was coming out was $d(n)$ and this is $x(n)$ ok. So, since we do not know these coefficients, we take general w_0 and unknown $w_0 x(n) + w_1 x(n-1)$ equal to $d(n)$ ok.

$$w_0 x(n) + w_1 x(n-1) = d(n)$$

So, there are infinite solutions this actually gives a straight line we have seen ok. At any point on the straight line is a solution of which this is also a valid solution ok, but only thing we do not know.

And of course, you remember the procedure that if w_N is the current estimate then from w_N we try to arrive at a point on this straight line ok. So, that this equation is satisfied, but distance from that point to w_N is minimum that is it is orthogonal perpendicular to this line and so on and so forth. In fact, you can see one thing if we have 3 coefficients suppose what is in this case where I have got 3 coefficients. The same logic will hold here it will be w_0 general $w_0 x_N$ equal to d_N . So, this is you know it has 3 x's $w_0 w_1 w_2$.

$$w_0 x(n) + w_1 x(n - 1) + w_2 x(n - 2) = d(n)$$

So, 3-dimensional plot and this will be a plane. So, it could be a plane you know like this is a plane and somewhere in the plane I have got this point optimal point this point and then we take a w_N then we project on this plane earlier it was straight line now you project on this plane this will take to be w_N plus 1. Then we move to N from N th index to N plus 1th index you get another plane. So, you project this point you know this vector on that plane get w_N plus 2 and so on and so forth ok. But at a time at any index, you just are considering only one plane and on that you are projecting the previous weight vector or current weight vector rather we are projecting orthogonally and that is how you do.

In the case of affine projection we generalize like this.

Lecture-30 : Affine Projection Algorithm (APA)

Lecture 30

Affine projection algorithm (APA)

$x(n)$
 $\begin{bmatrix} \hat{w}_0 & \hat{w}_1 \end{bmatrix}$
 $d(n)$

$w_0 x(n) + w_1 x(n-1) = d(n)$

$x(n)$
 $\begin{bmatrix} \hat{w}_0 & \hat{w}_1 & \hat{w}_2 \end{bmatrix}$
 $d(n)$

$w_0 x(n) + w_1 x(n-1) + w_2 x(n-2) = d(n)$

MORE VIDEOS

Here just consider a general case these are true parameters general case we have got x_N and in the absence of noise we have got d_N . Since I do not know these coefficients the general equation, I write it will be in terms of this unknowns $w_0 x_N$ plus to d_N which also you can write as $w^T x_N$ equivalent to $x^T N w$ is equal to $d_N w$

$$w_0 x(n) + w_1 x(n-1) + \dots + w_{N-1} x(n-N+1) = d(n)$$

$$\underline{w}^T \underline{x}(n) \equiv \underline{x}^T(n) \underline{w} = d(n)$$

of course, is that coefficient vector unknown coefficients we have to determine the true values and x_N is the data vector at the current index N that is current data and some of the past data. So, this is a simple if I have filter output equation this is what you have. Now in the case of APA we try to look find out this w_0 to w_N minus 1 not just from one plane in fact I should call it hyper plane because it is more than three-dimension plane is in the three dimensions.

Lecture-30 : Affine Projection Algorithm (APA)

$\hat{w}_0, \hat{w}_1, \dots, \hat{w}_{N-1}$

$\underline{w}^T \underline{x}(n) = d(n)$

$\underline{w} = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ w_{N-1} \end{bmatrix}$

$\underline{x}(n) = \begin{bmatrix} x(n) \\ x(n-1) \\ \vdots \\ x(n-N+1) \end{bmatrix}$

$\Rightarrow \underline{w}^T \underline{x}(n) = \underline{x}^T(n) \underline{w} = d(n)$

$\hat{w}_0 x(n) + \hat{w}_1 x(n-1) + \dots + \hat{w}_{N-1} x(n-N+1)$

MORE VIDEOS

So, let us just use the term hyper plane. So, we try to find out w_0 w_1 and this w_{N-1} all this not just from one hyper plane. We assume that since the coefficients are not changing at the previous clock $N-1$ th clock also if I have this that is at $N-1$ th clock if I input x_{N-1} , there is a corresponding filter output will be filter coefficients are not changing for the same coefficients at N th clock these are the data and you get $w^T x_N = d_N$ at $N-1$ th clock it should be d_{N-1} , that is w should be such that $w^T x_N$ at N th clock should be d_N the d_N that is coming out w^T at $N-1$ th clock it would give you d_{N-1} .

$$\underline{w}^T \underline{x}(n-1) = d(n-1)$$

So, simultaneously this should be satisfied this should be satisfied this one this one this one there is an N th clock w should satisfy this equation same w should satisfy at $N-1$ th clock this equation and dot dot dot dot like that up to we go p terms $N-1$ $N-2$ up to maybe $N-p$. p is called projection ordered.

$$\underline{w}^T \underline{x}(n-p) = d(n-p)$$

So, we are I am looking to solve for or obtain a w which simultaneously satisfy not just I mean one hyper plane or one equation one plane or one straight line in the case of two

dimension it will satisfy multiple such planar equations hyper plane equations at Nth clock N minus 1th clock N minus 2th clock dot dot dot N minus pth clock simultaneously. That means wherever they intersect my w must belong there because the planes to explain that let me consider just three coefficients only let me consider three coefficients.

$$\underline{w} = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ w_{N-1} \end{bmatrix}$$

$$\underline{x}(n) = \begin{bmatrix} x(n) \\ x(n-1) \\ \vdots \\ x(n-N+1) \end{bmatrix}$$

$$w_0 x(n) + w_1 x(n-1) + \dots + w_{N-1} x(n-N+1) = d(n)$$

$$\Rightarrow \underline{w}^t \underline{x}(n) = d(n)$$

$$w_0 x(n-1) + w_1 x(n-2) + \dots + w_{N-1} x(n-N) = d(n-1)$$

$$\Rightarrow \underline{w}^t \underline{x}(n-1) = d(n-1)$$

$$\vdots$$

$$\underline{w}^t \underline{x}(n-p) = d(n-p)$$

p: Projection order

Suppose you have one equation which is $w_0 x_N$ plus $w_1 x_{N-1}$ plus $w_2 x_{N-2}$ equals to d_N that is in short $w^T x_N$ is d_N and at $N-1$ th clock you have got $w^T x_{N-1}$ vector there is x_{N-1} $N-2$ $N-3$ is d_{N-1} just 2.

$$w_0 x(n) + w_1 x(n-1) + w_2 x(n-2) = d(n)$$

$$\Rightarrow \underline{w}^t \underline{x}(n) = d(n)$$

$$\underline{w}^t \underline{x}(n-1) = d(n-1)$$

So, this is one plane. This is one plane that is this is this plane and another one will be another plane another one will be another plane maybe like this. So, these two planes actually will intersect let me try to do a better diagram. Suppose it like this. So, this plane has you know this is this is this plane this is this plane and that is this plane and they intersect the two planes will intersect at one line that you can understand you take two you

know piece of papers if they intersect that will be a straight line I mean from three dimension it becomes two dimension that is plane had three variables the intersection will be a straight line we have actually two variables that is obvious we eliminate one of the three w_0 or w_1 or w_2 and you get one equation from this. So, that is this that is obvious. Now, here what will you do is this suppose your w_N is somewhere here and optimal one optimal one will be satisfying both these equations these equations.

So, that should lie optimal vector should lie in both the planes therefore, it should lie on the intersection which is common to both the planes. So, maybe this is where your optimal one is w_{opt} the two system parameters. Now, what you are doing if you are doing NLMS from here we will just take a projection on this plane. So, this will be a new vector this will be a new vector. So, this will be w_N plus 1, but you see w_N plus 1 and w_{opt} there is so much of gap, but in APA affine projection algorithm we will not project w_N on this plane or on this plane we will project on that intersection in this case because they are three-dimensional intersection is two dimensional which is straight line.

In general, if each hyper plane is supposing N dimensional then that intersection will be between 2 will be N minus 1 between 3 will be N minus 2 dimensional and like that this you can visualize easily. So, we will take a perpendicular there. So, we will be drawing you know perpendicular on this line which is intersection. So, that will be my w_N plus 1 this vector is w_N plus 1 under APA and now see this is now much closer to this optimal one, then this guy under NLMS I would have projected here. So, much of distance between the optimal one and the projected point, but if I project on this plane not on this plane or this plane separately, but on the intersection between the two planes then I hit a point which is much closer to the optimal one.

So, I am already very close to optimal one. So, I will require much less iterations to reach the optimal one than the NLMS this is the philosophy this you can extend to the general N dimensional case. That means, optimal the here the optimization will be this we should minimize or before that maybe some definitions will help us at this stage. These equations can be combined into a matrix vector form like this. If I define $\underline{x}_N$ where this is $\underline{x}_N$ $\underline{x}_N$ vector we already defined the input data vector at N s clock then $\underline{x}_N$ minus 1 dot dot dot dot $\underline{x}_N$ minus N plus 1 this $\underline{x}_N$.

And if I define $\underline{d}_N$ vector as current $\underline{d}_N$ then previous $\underline{d}_N$ dot dot dot plus $\underline{d}_N$ sorry I made a mistake here this should not be this every $\underline{x}_N$ vector is of length capital N, but how many I have I have x of N here x of N minus 1 here x of N minus 2 there the columns. So, last is $\underline{x}_N$ minus p. So, it should be $\underline{x}_N$ minus p all right this is my $\underline{x}_N$ vector. So, this N cross p plus 1 N minus 0 N minus 1 up to N minus p should be p plus 1 this is the matrix. And you can see all these equations they imply this that $\underline{x}_N^T \underline{W}$ should be $\underline{d}_N$ vector because $\underline{x}_N^T \underline{W}$ if it is a transpose of this first column will become first row.

$$\underline{X}^T(n) \underline{w} = \underline{d}(n)$$

So, column will become row means it will be a row x transpose N $\underline{x}_N$ was column x transpose N is row then will be this way this second column will become second row. So, again x transpose N minus 1 $\underline{x}_N$ minus 1 is column x transpose N minus 1 is row dot dot

So, I had one constraint I have one here next here next to total P plus 1 constraint that is this should be satisfied simultaneously this should be satisfied simultaneously next will be satisfied simultaneously. So, I have one constraint here that will require one Lagrange multiplier say lambda 1 next is this that will require another one and like that. That means, I will now consider a general function W and you can call it lambda vector lambda vector has got all the Lagrange multipliers required. Wait a minute N N minus 1 fine. So, lambda 0 lambda 1 dot dot dot lambda P that is we should minimize this subject to first use lambda 0 that is constraint is $x^T W - d^T$ then lambda 1 these are all Lagrange multipliers earlier I took only one now I have got so many because of these constraints.

Because you see if I differentiate this with respect to lambda 0 equate to 0 all other fellows will disappear only this will remain and that will equate to 0. So, that condition will be satisfied if I differentiate this with respect to lambda 1 then this quantity this will result and that will be equated to 0 others only disappear. So, this the second constraint next constraint will be satisfied so on and so forth plus dot dot dot dot last one is lambda P $x^T W$ alright. So, this I have to minimize. So, this I can you can see I can write in this form first term remains as it is then if I say lambda transpose times x^T we will verify minus $d^T W$ vector minus d^T vector.

$$\underline{\lambda} = \begin{bmatrix} \lambda_0 \\ \lambda_1 \\ \vdots \\ \lambda_p \end{bmatrix}$$

Let us see this we have seen in the previous page this is the constraint that is $x^T W$ should be equal to d^T we can even go into you know term wise $x^T W$ minus d^T .

So, this part will be what this part will be a vector like this x transpose we have already seen in the previous page minus dN then x transpose N minus 1 minus dN minus 1 dot dot dot dot dot I already discussed a while ago. So, this is this vector matrix into column vector is a column vector minus again column vector. So, total is a column vector this is a row vector row into column is a scalar alright. So, this is xN transpose xN was a column vector x transpose N W this is a filter output that minus dN I do not know W .

So, I should have a W which satisfies this is equal to 0 . Now if I have lambda transpose now if I have lambda transpose just I transpose it. So, it will be a row vector lambda 0 lambda 1 lambda p lambda 0 lambda 1 dot dot lambda p . So, lambda 0 will multiply this. So, that is what we will get this term this term plus lambda 1 times next.

So, we will get this term and dot dot dot dot. So, this is actually entire equation we can write like this compactly, but actually this is this the moment I differentiate L with respect to lambda 0 equate to 0 this only this much will remain and this will become 0 . So, x transpose N W will be dN . So, that constraint will be satisfied if I differentiate this with

respect to lambda 1 equate to 0 only this part will remain and equate to 0 means it will lead to $x^T (N - 1) W = d(N - 1)$. So, then the second constraint will be satisfied so on and so forth, but this whole expression I am writing in a compact manner like this all right.

$$\lambda = \begin{bmatrix} \lambda_0 \\ \lambda_1 \\ \vdots \\ \lambda_p \end{bmatrix}$$

$$\text{minimizing } \|w - \tilde{w}(n)\|, \text{ subject to } x^k(n) w = d(n)$$

$$\mathcal{L}(w, \lambda) = \|w - \tilde{w}(n)\| + \lambda_0 (x^k(n) w - d(n)) + \lambda_1 (x^k(n-1) w - d(n-1)) + \dots + \lambda_p (x^k(n-p) w - d(n-p))$$

$$= \|w - \tilde{w}(n)\| + \lambda^k \left[\begin{matrix} x^k(n) w - d(n) \\ x^k(n-1) w - d(n-1) \\ \vdots \\ x^k(n-p) w - d(n-p) \end{matrix} \right]$$

So, with that I can go to the next page. So, first let me rewrite this is $x^T (N - K) W = d(N - K)$ and this we equate to 0. So, this constraint satisfied all right. So, separately we have to carry out these other partial derivatives also that is $\frac{\partial}{\partial W} L$ and that is partial derivative of this with respect to each component of W put it in a stack and that again you have to I mean equate to 0 this is 0 vector now. So, this actually will lead to the value of lambda.

$$\begin{aligned}
 \mathcal{L}(\underline{W}, \underline{d}) &= \|\underline{W} - \underline{W}(n)\|^2 + \sum_{n=0}^p \left[\underline{x}^T(n) \underline{W} - \underline{d}(n) \right] \\
 u=0, \dots, p \quad \frac{\partial \mathcal{L}}{\partial \underline{W}} &= \underline{x}^T(n-u) \underline{W} - \underline{d}(n-u) \Rightarrow \text{"=0"} \Rightarrow \underline{x}^T(n-u) \underline{W} \\
 &= \underline{d}(n-u) \\
 \nabla_{\underline{W}} \mathcal{L} &= \underline{0} \quad +
 \end{aligned}$$

So, all these we will do in the next class. Thank you very much.
