Lecture No # 38

Formulation of the RLS Algorithm

We are considering recursive least squares transversal filter. You remember we had a data matrix at nth clock built using data obtained from n equal to 0 to I mean time equal to 0 to time equal to n. I do us like this $x_0 \ x_1 \ \text{dot dot dot dot} \ x_{n-1}$. So, in one cycle delayed version $x_{n-2} \ x_{n-1} \ \text{dot dot dot dot}$. Lastly x_{n-N+1} here it is $n - \text{capital } N + 1$. So, this dot dot dot dot and there was d_N vector.

$$\underline{d}(n) = \begin{bmatrix} d(0) \\ d(1) \\ \vdots \\ d(n) \end{bmatrix}$$

So, these are all old stuff that is why I am not explaining them again. You can go back to previous lecture and see how they came and all that. Then the error vector at nth clock was d_N minus x_n filter weight vector. $\underline{W}$ was just a general filter weight vector $w_0 \ w_1 \ \text{dot dot dot} \ w_{N-1}$.

$$\underline{e}(n) = \underline{d}(n) - X_n \underline{w}$$

$$\underline{w} = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ w_{N-1} \end{bmatrix}$$

Lecture 38: Formulation of the RLS Algorithm

Lecture 35

$$\underline{w} = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ w_{N-1} \end{bmatrix}$$

$$\underline{e}(n) = \underline{d}(n) - \underline{x}_n \underline{w}$$

$$\underline{x}_n = \begin{bmatrix} x(n) & x(n-1) & \dots & x(n-(N-1)) \\ x(n) & x(n-1) & \dots & x(n-(N-1)) \\ \vdots & \vdots & \ddots & \vdots \\ x(n) & x(n-1) & \dots & x(n-(N-1)) \\ x(n) & x(n-1) & \dots & x(n-(N-1)) \end{bmatrix}$$

$$\underline{d}(n) = \begin{bmatrix} d(n) \\ d(n) \\ \vdots \\ d(n) \end{bmatrix}$$

MORE VIDEOS

You can see one thing $x_n w$. So, if you multiply this by a w you start with the last row this times w that is a filter weight filter output vector at n th clock because x_n into w_0 x_n minus 1 into w_1 dot dot dot this into w_{N-1} and summation. So, that we know is the filter output at n th clock. Then next row times the same w . So, w_0 times x_n minus 1 w_1 times x_n minus 2 dot dot dot the summation there is a filter output at n minus 1th clock so on and so forth.

So, this is actually giving a vector of filter weight outputs filter outputs at n th clock n minus 1 at n minus 2 is up to 0th and when that is subtracted from this d_N then d_N minus filter output at n th clock so that will be output error at n th clock then output error at n minus 1th clock and all that there is overall error vector. Our purpose is to minimize the norm square that is if we take the norm square of this vector which I have forgetting factor of course, that is if you take it was like you know I mean current term is $e^2(n)$ next was some λ times $e^2(n-1)$ is the current term then λ^2 times $e^2(n-2)$ and dot dot dot λ^N times $e^2(0)$ where λ real and λ greater than 1 less than 1 greater than 0, but typically very close to 1 maybe 0.99 something like that.

$$||e(n)||^2 = e^2(n) + \lambda e^2(n-1) + \lambda^2 e^2(n-2) + \dots + \lambda^N e^2(0)$$

So, what it does it just recap when λ is λ or λ^2 or λ^3 and all that its value is not that less. So, in this summation the current contribution e^2 or previous cycle contribution e^2 $N-1$ and all they dominate, but contribution from remote past they diminish their effect is much less that helps us in concentrating on the norm square of the error vector on the current history not on past history because I mean system characteristics and all that you know can change from time to time.

So, we should focus on this norm square from the current history point of view all those were explained last time ok. And by minimizing this we obtain the recursive least squares estimate of the filter weights $\mathbf{W}_N$ at N th clock as this, this is $\mathbf{X}_N$ this is diagonal matrix I will write about it though you all know this $\mathbf{X}_N$ transpose inverse ok, where the diagonal matrix these of course, assume that $\mathbf{X}_N$ matrix there is this matrix the columns are linearly independent this is a full rank which means number of rows must be at least equal to number of column or more.

$$\mathbf{w}_n = \left[(\mathbf{X}_n^t \mathbf{\Lambda}_n \mathbf{X}_n)^{-1} \mathbf{X}_n^t \mathbf{\Lambda}_n \right] \mathbf{d}(n)$$

So, that means N how many columns we have N number of columns 0 1 like that ok. So, small n should be at least equal to N or more otherwise it will be rank deficient. So, that is what we are considering we are assuming that this $\mathbf{X}_N$ is full rank which is not possible if small n is less than N ok.

So, even when small n is greater than N it may or may not be possible, but that is what we are assuming it is invariable we will talk about that more later this is what we have derived earlier. Now, point is that N th clock you got all this data you carry out all this business and find out this filter coefficient vector ok, which is the best estimate recursive least squares estimate use it for filtering ok, the input data vector input data ok. Next time at $N+1$ th clock from $\mathbf{X}_N$ we go to $\mathbf{X}_{N+1}$ one more row comes in where a new data $\mathbf{X}_{N+1}$ that comes then of course, $\mathbf{X}_N$ $N-1$ they are all already obtained past data, but at least one new data comes $\mathbf{X}_{N+1}$ using that I mean I construct a new row. So, the matrix

size increases number of rows goes up by 1. Similarly, D_N another new D_{N+1} comes D_N also goes up ok D_N also goes up by 1.

So, my previous estimate W_N will not work I have to replace X_N by X_{N+1} this should be λ^{N+1} ok that is $1 \cdot \lambda \cdot \dots \cdot \lambda$ to the power N minus 1 λ^N another term λ to the power $N+1$ and again X_{N+1} and all that you know D_{N+1} . So, shall we do like this that at every clock we carry out this whole computation find out W_N and the filter next time X_N matrix changes to X_{N+1} D_N vector changes to D_{N+1} .

Lecture 35

$$\underline{W} = \begin{bmatrix} W_0 \\ W_1 \\ \vdots \\ W_{N-1} \end{bmatrix}$$

$$\underline{e}(n) = \underline{d}(n) - \underline{X}_n^T \underline{W}$$

$$\|\underline{e}(n)\|^2 = e^2(n) + \lambda e^2(n-1) + \lambda^2 e^2(n-2) + \dots + \lambda^N e^2(0)$$

$$\lambda: \text{real}, 0 < \lambda < 1 \quad (\approx 0.99)$$

$$\underline{W}_n = \left[\left(\underline{X}_n^T \underline{\Lambda}_n \underline{X}_n \right)^{-1} \underline{X}_n^T \underline{\Lambda}_n \right] \underline{d}(n)$$

$$\underline{\Lambda}_n = \begin{bmatrix} \lambda^n & 0 & \dots & 0 \\ 0 & \lambda^{n-1} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda^1 \end{bmatrix}$$

$$\underline{X}_n = \begin{bmatrix} x(n) & x(n-1) & \dots & x(n-N+1) \\ x(n) & x(n-1) & \dots & x(n-N+1) \\ \vdots & \vdots & \ddots & \vdots \\ x(n) & x(n-1) & \dots & x(n-N+1) \end{bmatrix}$$

$$\underline{d}(n) = \begin{bmatrix} d(n) \\ d(n) \\ \vdots \\ d(n) \end{bmatrix}$$

$$\underline{X}_n \rightarrow \underline{X}_{n+1}$$

$$\underline{d}(n) \rightarrow \underline{d}(n+1)$$

So, let us again compute the same thing replacing N by $N+1$ get W_{N+1} again do filtering that we cannot do that will be too much you know we should rather recursively obtain generate W_N to W_{N+1} recursively that is instead of carrying out the whole computation this inverse formula pseudo inverse formula just using some simple update relation like we had in LMS where from current W_N we go to next W_{N+1} by some extra update term can we generate from W_N W_{N+1} similarly recursively without going

through this base of this computation that is what we will be approaching because lot of things are common between W_N and W_{N+1} because matrix X_N getting changed to $N+1$ just one extra row is coming, but previous part remain same. So, that is common with the previous case and current case similarly D_N vector one extra term D_{N+1} comes at the bottom, but rest of the terms are common ok. Therefore, there may be possible it may be possible to find the relation between W_N and W_{N+1} because just one extra row has come up here in X_N one extra element has come up in D_N ok other things are common.

Lecture 35

$$\underline{W} = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ w_N \end{bmatrix}$$

$$\underline{e}(n) = \underline{d}(n) - \underline{X}_n \underline{W}$$

$$\|\underline{e}(n)\|^2 = e^2(n) + \lambda e^2(n-1) + \lambda^2 e^2(n-2) + \dots + \lambda^n e^2(0)$$

$$\lambda: \text{real}, 0 < \lambda < 1 \quad (\text{loss})$$

$$\underline{W}_n = \left[\left(\underline{X}_n^T \underline{\Lambda}_n \underline{X}_n \right)^{-1} \underline{X}_n^T \underline{\Lambda}_n \right] \underline{d}(n)$$

$$\underline{\Lambda}_n = \begin{bmatrix} \lambda^{n-1} & 0 \\ 0 & \ddots & 0 \\ 0 & \dots & \lambda \end{bmatrix}$$

$$\underline{X}_n = \begin{bmatrix} x(n) & x(n-1) & \dots & x(n-N+1) \\ x(n-1) & x(n-2) & \dots & x(n-N+2) \\ \vdots & \vdots & \ddots & \vdots \\ x(n-N+1) & x(n-N+2) & \dots & x(n-N+N) \\ x(n) & x(n-1) & \dots & x(n-N+1) \end{bmatrix}$$

$$\underline{d}(n) = \begin{bmatrix} d(n) \\ d(n-1) \\ \vdots \\ d(n-N+1) \end{bmatrix}$$

Generate $\underline{W}_n \rightarrow \underline{W}_{n+1}$ recursively

So, why not try and find out some relation between W_N and W_{N+1} which will be of course, recursive relation from W_N you should be able to generate W_{N+1} that is what the whole goal is ok to generate W_{N+1} from W_N recursively all right. To do this I mean today I need to do certain things first then we can go into the derivation derivation is very interesting I will just introduce certain change in notation I mean earlier I called this vector this to be vector X_N then this was Z inverse X_N and so on and so forth. Now, that will be slightly changed now I will call this to be like in the LMS case this to be X_N transpose that is now my X_N definition is the data vector at the filter input at N th clock

So, if it is XN you see it is XN transpose. So, this will be XN minus 1 transpose right so on and so forth this will be $X0$ vector transpose this will be $X1$ vector transpose all right.

So, then I rewrite XN like this this is just a change of notation conceptually there is nothing new this was just using that notation. So, if I write it down you can see one thing if I divide this this upper half is nothing but XN minus 1 instead of N I have N minus 1 I will go from X0 transpose X1 transpose dot dot up to XN minus 1 transpose. So, this is XN minus 1 and this bottom I have got 1 X transpose N that has come up.

$$\underline{X}_n = \begin{bmatrix} X_{n-1} \\ x^t(n) \end{bmatrix}$$

So, this is a relation we will be using. So, we will be using this notation this is one thing. Another thing is very famous matrix inversion lemma. This is a very general layout which we will not discuss here a special case which is applicable to us that all will be discussed that will make things simpler. And this lemma is very useful in you know this adaptive signal processing statistical signal processing and all that.

The image shows a blackboard with handwritten mathematical expressions. On the left, there is a vector x_n defined as a column vector of elements $x(0), x(1), \dots, x^{t(n)}$. To the right of this, there is an equals sign followed by a matrix representation of the same vector, where the top element is x_{n-1} and the bottom element is $x^{t(n)}$. Below the equations, the text "Matrix inversion lemma" is written and underlined. In the bottom right corner, a small inset shows a man speaking.

$$x_n = \begin{bmatrix} x(0) \\ x(1) \\ \vdots \\ x^{t(n)} \end{bmatrix} = \begin{bmatrix} x_{n-1} \\ x^{t(n)} \end{bmatrix}$$

Matrix inversion lemma

So, this is general result I am quoting I will be using it in that recursively square derivation but this is a separate result. So, given A to be maybe N cross N the square matrix invertible α any scalar real or complex does not matter and A some N cross 1 vector A is invertible then if I have a form like this A matrix it was already invertible but an extra component another matrix is getting added with that then what happens to the inverse assuming that inverse exists that additional component is A column vector into its transpose row vector. So, column into row it is an additional matrix I introduce the α scalar here, α could be 1 also but we want to be more general so α is this. So, let us keep a provision of α assume invertible that is assume exists that is not only A is invertible if along with A we add this $\alpha A, A$ transpose this total matrix also if we assume invertible

then what is this inverse. Then claim is this is equal to A inverse minus scalar alpha divided by 1 plus alpha I get scalar A transpose which is a row vector now capital A inverse A.

So, capital A is a matrix A inverse is a matrix small a is a column vector. So, A inverse small a is a column vector this is a row vector row into column is a scalar. So, this whole thing is a scalar this times a matrix of course, because it is a matrix this is a matrix this matrix is A inverse matrix A A transpose. So, A is a column vector A transpose row vector. So, this is the matrix at once again A inverse this is a result I will prove this result it is not very difficult.

Handwritten notes on a blackboard:

$$\underline{x}_n = \begin{bmatrix} \underline{x}_n^{(1)} \\ \underline{x}_n^{(2)} \\ \vdots \\ \underline{x}_n^{(n-1)} \\ \underline{x}_n^{(n)} \end{bmatrix} = \begin{bmatrix} \underline{x}_{n-1} \\ \underline{x}_n^{(n)} \end{bmatrix}$$

• Matrix inversion lemma

Given: A to be a $n \times n$, invertible matrix
 α : any scalar
 $\underline{a}$: $n \times 1$ vector

$(A + \alpha \underline{a} \underline{a}^T)^{-1}$: Assume exists
 $\hookrightarrow = A^{-1} - \frac{\alpha}{1 + \alpha \underline{a}^T A^{-1} \underline{a}} \cdot \underline{A}^{-1} \underline{a} \underline{a}^T \underline{A}^{-1}$

To prove that right hand side is the inverse of A plus small alpha A A transpose what I have to do I will multiply this quantity within this bracket by the right hand side and so this is identity. Suppose you have to show that A inverse is B what will you do you then show A B is I of course, A B they are square. So, there are square matrices and A inverse is called B. You have to show that A inverse you have to show that certain A inverse is equal to certain B how to show if I can show A B equal to identity that means B is the B is A inverse

I because A square and A is supposed to be invertible. So, A inverse A into B is A inverse I A inverse I is A inverse A inverse A is I .

So, I B is B . So, B equal to A inverse. So, assuming A to B invertible if you have to show that A inverse equal to some matrix B how to show that just take A and B multiply A with B A B . So, that equal to I that means A is the inverse of B B is the inverse of B that we know this from basic matrix algebra which you all studied in fact in school. So, let me erase this part once again I just write the formula quickly for you that was A plus assuming this to be invertible then the claim these are claim this inverse is equal to A inverse minus α by times A inverse. These are claim proof this whole thing into right hand side that is if I do this A plus α A A transpose this quantity not inverse this quantity into right hand side right hand side we show that this quantity into right hand side is equal to identity means right hand side is the inverse of this as I told you A B A inverse is B means A B is I if you can show A into B is I .

$$(\underline{A} + \alpha \underline{a} \underline{a}^t)^{-1} = \underline{A}^{-1} - \frac{\alpha}{1 + \alpha \underline{a}^t \underline{A}^{-1} \underline{a}} \underline{A}^{-1} \underline{a} \underline{a}^t \underline{A}^{-1}$$

So, that thing works here right this is what I have to show. So, we just work out this term little messy A plus α A A transpose right hand side is our claim is this part before I write this I can make it with some simplifications you see one thing A transpose A inverse A this is a scalar because A as I told already A is a matrix assuming it is invertible A inverse is a matrix matrix into column vector A is a column vector A transpose is a row vector row into column is a scalar. Let me call that scalar γ in the denominator I have 1 plus γ which is equal to say suppose I call β say say then notationally it becomes simplified nothing else. So, it becomes α by 1 plus γ sorry there is an α here.

$$(\underline{A} + \alpha \underline{a} \underline{a}^t). RHS = \underline{I}$$

$$\underline{a}^t \underline{A}^{-1} \underline{a} = \beta$$

So, I cannot do like this. So, let me keep it just gamma just fine or maybe instead of gamma because gamma I will be using afterwards. So, we have to be cautious maybe call it beta say. So, this is 1 plus alpha by 1 plus alpha into beta right 1 plus alpha by 1 plus alpha into beta times as before. So, if I multiply A A inverse that is identity then alpha A A transpose A inverse alpha A A transpose A inverse then A times this quantity. So, A A inverse cancels identity.

$$(A + \alpha \underline{a} \underline{a}^t) \left(\underline{A}^{-1} - \frac{\alpha}{1 + \alpha\beta} \underline{A}^{-1} \underline{a} \underline{a}^t \underline{A}^{-1} \right)$$

So, minus alpha by 1 plus alpha beta A n this is A A transpose A inverse alright and lastly this term with this term. So, alpha square by 1 plus alpha beta alpha square by 1 plus alpha A A transpose with B C, but actually not B C A A transpose A inverse A A transpose A A inverse looks messy, but actually not. This term looks very complicated A column vector then row vector then matrix then A column vector then row vector all that, but you see if I take out this part this is scalar and this is this beta is it A transpose A A. So, at beta is a scalar. So, beta is a scalar like 2 3 4 anything I can pull it out ok.

$$= \underline{I} + \alpha \underline{a} \underline{a}^t \underline{A}^{-1} - \frac{\alpha}{1 + \alpha\beta} \underline{a} \underline{a}^t \underline{A}^{-1} - \frac{\alpha^2}{1 + \alpha\beta} \underline{a} \underline{a}^t \underline{A}^{-1} \underline{a} \underline{a}^t \underline{A}^{-1}$$

So, alpha square beta. So, it is identity I plus alpha A A transpose A inverse these are all here as it is minus alpha square by 1 plus alpha beta this beta comes up here I can pull it out with a scalar. So, A A transpose A inverse A is a column vector A transpose is a row vector. So, this is a matrix matrix into matrix matrix same matrix here here here. So, I can take that common I plus rest are scalar. So, you can write does not matter you can first write the matrix and then scalar alpha times this matrix alpha scalar minus alpha by 1 plus alpha beta and then minus alpha square beta by 1 plus alpha beta.

$$= \underline{I} + \alpha \underline{a} \underline{a}^t \underline{A}^{-1} - \frac{\alpha}{1 + \alpha\beta} \underline{a}^t \underline{A}^{-1} - \frac{\alpha^2 \beta}{1 + \alpha\beta} \underline{a} \underline{a}^t \underline{A}^{-1}$$

$$= \underline{I} + \underline{a} \underline{a}^t \underline{A}^{-1} \left[\alpha - \frac{\alpha}{1 + \alpha\beta} - \frac{\alpha^2\beta}{1 + \alpha\beta} \right]$$

And let us see what happens alpha into 1 you can see easily alpha into 1 alpha minus alpha cancels the alpha square beta minus alpha square beta cancels. So, this whole thing is equal to 0. So, this is identity which proves that one is the inverse of the other that is if I call this matrix something say theta and this is let this matrix be phi then theta into phi identity.

$$= \underline{I}$$

So, phi is the inverse of theta, theta is the inverse of phi with the square matrices which proves this result ok. This is the result I will be using in derivation this is very famous result for signal processing in particular ok.

Lecture 38: Formulation of the RLS Algorithm

Proof: we show that $(\underline{A} + \alpha \underline{a} \underline{a}^t)^{-1} \cdot \text{RHS} = \underline{I}$

$$(\underline{A} + \alpha \underline{a} \underline{a}^t)^{-1} \left(\underline{A}^{-1} - \frac{\alpha}{1 + \alpha\beta} \underline{A}^{-1} \underline{a} \underline{a}^t \underline{A}^{-1} \right)$$

$$= \underline{I} + \alpha \underline{a} \underline{a}^t \underline{A}^{-1} - \frac{\alpha}{1 + \alpha\beta} \underline{a} \underline{a}^t \underline{A}^{-1} - \frac{\alpha^2\beta}{1 + \alpha\beta} \underline{a} \underline{a}^t \underline{A}^{-1}$$

$$= \underline{I} + \underline{a} \underline{a}^t \underline{A}^{-1} \left[\alpha - \frac{\alpha}{1 + \alpha\beta} - \frac{\alpha^2\beta}{1 + \alpha\beta} \right] = \underline{I}$$

And this is the result I will be using in the derivation of the RLS algorithm. And another thing very simple, but I will be using it is called block partitioning of matrices and multiplication block multiplication. Again this is from elementary matrices theory if you easily appreciate. Suppose you got a matrix A which is m cross n and a matrix B which is

n cross may be r you are multiplying obviously we will take this row into this column take this row next column and so on and so all of us know. But suppose I divide this matrix into sub matrices that is this may be L number of columns and this may be K number of columns that is L plus K equal to total number of column N.

So, this part I call A1 this part I call A2 and similarly here I take L so I take L here and this is K. So, this part of this matrix B I call B1 this I call B2 then by claim this will be same as claim this is same as equal to $A_1 B_1$ plus $A_2 B_2$ very simple. Consider this this is visually very clear A1. So, consider this A1 and A2 the first row first row of this total matrix A. So, this has one part this is one part and similarly if you take the first column of this total matrix B this is one part here one part here original A into B how will I how was I doing A into B this row times this column.

But that you can break as this times this plus this this times this that is what you have here you see $A_1 B_1$ means first row of A1 which is this into first column of B1 which is this. So, you are multiplying so that component is coming and additional component this into this is coming from here first row of this which is this much first column of this which is this much their product and you are adding. So, you are getting one element then you go to again this row times this means what this times this plus this times this, this times this means first row of A1 second column of B1 and again first row of A2 second column of B2 that is what you have here also $A_1 B_1$ first row into first column then first row into second column of B1. Similarly first row of A2 into first column of B2 then first row of A2 into second column of B2 that is what you are doing.

So, you get that result right. So, this way you can very simple you can take some examples of you know I mean maybe some 2 by 3 by 3 or 4 by 4 matrices and like that you know some simple matrix you can easily identify even otherwise also it is visually very clear. So, you can partition matrices like this blockwise ok, you can partition matrices blockwise and carry out the product like this. So, AB will be $A_1 B_1$ so A1 has L number of column so

this has L number of rows A2 has K number of columns so B2 has K number of rows so A1 B1 you can carry out the product and A2 B2 ok.

This way you can generalize further generalize like this A1 A2 and B matrix you are not only breaking here you are breaking here it is B1 B2 B3 B4 this is m cross n.

So, this was 1 minute L K ok. So, this was L this was K this part is m so this is your L this is your K. So, this is B matrix I divide like this so this part as the I carry out product of this A with this first. So, I use the previous philosophy it will be A1 B1 plus A2 B2 ok that will be A times this sub matrix. So, it will be this part first A1 B1 plus A2 B2 this will come here and then again you do this product total A matrix into this part. So, A1 B3 plus A2 B2 this simple this just generalization this what I will be using extensively in my derivation of the recursively square algorithm.

$$\begin{matrix}
 \xrightarrow{l} & \xrightarrow{n} \\
 \begin{bmatrix} A_1 & A_2 \end{bmatrix} & = & \begin{bmatrix} B_1 & B_2 \end{bmatrix} \\
 \downarrow m & & \downarrow p \\
 & & \downarrow n
 \end{matrix}$$

$$= \begin{bmatrix} A_1 B_1 & A_1 B_2 \\ A_2 B_1 & A_2 B_2 \end{bmatrix}$$

So, this algorithm I will develop in the next class. Thank you very much.
