Lecture - 14
Variational Approach to Optimal Control Systems (Continued)

So, welcome friends to this class. This is again we are a still continuing the variational approach to optimal control system. In the previous class we have determine the Hamiltonian and the system in the Hamiltonian we can define by these 4 equations.

(Refer Slide Time: 00:54)

Variational Approach to Optimal Control Systems

In terms of Hamiltonian H^*

The Control Equation $\left(\frac{\partial \mathcal{H}}{\partial \mathbf{u}}\right)_* = 0$

The State Equation $\left(\frac{\partial \mathcal{H}}{\partial \lambda}\right)_* = \dot{\mathbf{x}}^*(t)$

The Costate Equation $\left(\frac{\partial \mathcal{H}}{\partial \mathbf{x}}\right)_* = -\dot{\lambda}^*(t)$

The Boundary Condition $\left[\mathcal{H}^* + \frac{\partial S}{\partial t}\right]_{t_f} \delta t_f + \left[\left(\frac{\partial S}{\partial \mathbf{x}}\right)_* - \lambda^*(t)\right]_{t_f}' \delta \mathbf{x}_f = 0$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

Last is my boundary condition, so in a given problem my first 3 equation always remain the same, but the final this last equation can change according to the condition of my end points. In all the case my initial points are given, but end points can vary problem to problem if we will take the different systems my first system is the fixed final time and the fixed final state system. We already have been discussed before.

(Refer Slide Time: 01:34)

So, I am given with t_0 , $x(t_0)$ this normally is given. This is my t_f point if I will fix up the end point at $x(t_f)$. So, if variation will take place subjected to the fixed initial point and the fixed final point initial point we already are considering for all the cases to be fixed, but as in first case if we will fix up the end point. So, what will be the condition my δx_f will be 0 my δt_f will also be 0.

(Refer Slide Time: 02:48)

Different Types of Systems

1. Fixed-Final Time and Fixed-Final State System
$$\delta t_f = 0; \delta x_f = 0$$
2. Free-Final Time and Fixed-Final State System $\delta t_f = 0$
$$\left(\mathcal{H} + \frac{\partial S}{\partial t} \right)_{*t_f} = 0.$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, these 2 delta t f and delta x f will be 0, this means delta t f is 0 delta x f is 0, so last equation will not appear in the problem. But t f and the x t f they already are given that is why they are fixed. So, we are with the final condition.

(Refer Slide Time: 03:36)

So, this I know the initial condition I know the final condition based on this I can solve my first 3 equations. My second cases the free final time, but the fixed final state the system is free final time means my final state is fixed. So, I am given with the t_0, x of t_0 my x, t_f is fixed and t_f is free. So, if this is x star of t , this is t_f and let say this is t_f plus delta t_f . So, I can say this is my x, t which is nothing but x star of t plus delta x of t . So, that is my second case which is the free final time, final time is free and the fixed final state where x, t of is free.

So, my trajectory can land anywhere this we are x, t_f remain the fixed. So, in this case if we will see to my final condition as x, t_f is specified. So, what I will have? I have delta x, t_f to be 0. So, delta x, t_f will be 0, but, so H plus del S by del t . So, what is left? H plus del S by del t at t equal to t_f point, delta t_f that must be equal to 0 and this delta t_f is arbitrary. So, delta t_f is arbitrary. So, the coefficient of delta t_f is 0, this means H plus del S by del t at t equal to t_f point that will be equal to 0. So, we will have H plus del S by del t at t_f point that will be 0.

(Refer Slide Time: 06:42)

Different Types of Systems

3. Fixed-Final Time and Free-Final State System $\delta x_f = 0$

$$\left(\frac{\partial S}{\partial \mathbf{x}} - \lambda^*(t) \right)_{*t_f} = 0 \quad \lambda^*(t_f) = \left(\frac{\partial S}{\partial \mathbf{x}} \right)_{*t_f}$$

4. Free-Final Time and Independent Free-Final State

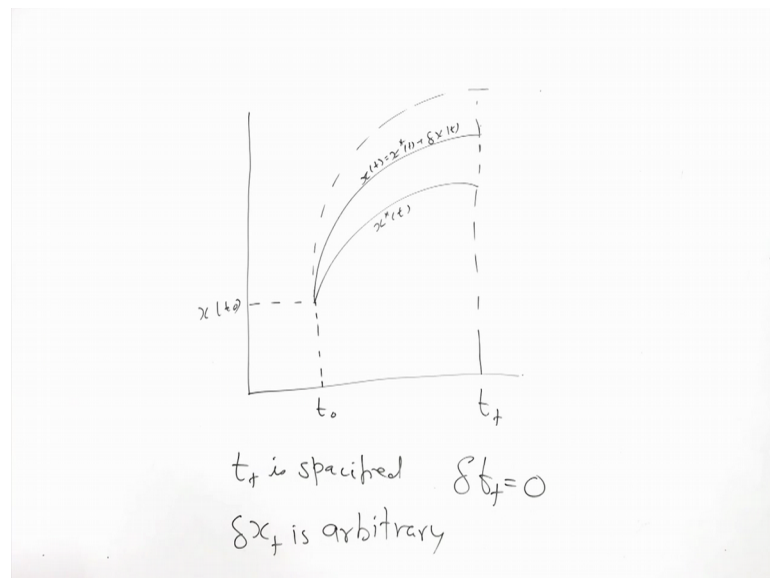

$$\left(\mathcal{H} + \frac{\partial S}{\partial t} \right)_{*t_f} = 0$$

$$\left(\frac{\partial S}{\partial \mathbf{x}} - \lambda^*(t) \right)_{*t_f} = 0.$$

IIT POORKEE NPTEL ONLINE CERTIFICATION COURSE

So, this is my second case the third case naturally if we will have the fixed final time and free final state system.

(Refer Slide Time: 06:57)

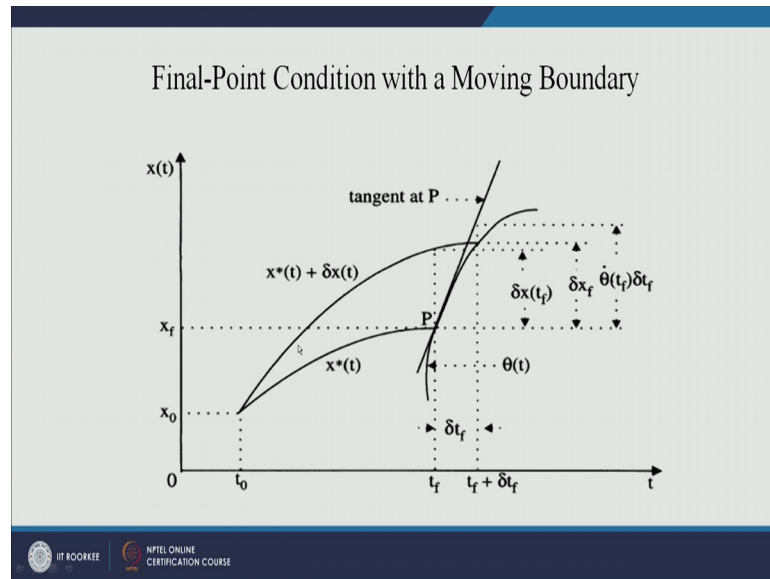

So, we have the free final state and fixed time. Again we start with $t_0, x(t_0)$ and this t_f is specified, t_f is. So, t_f will be fixed if this is my $x^*(t)$, so my trajectory can go anywhere. So, this will be my $x(t)$ which is $x^*(t) + \delta x(t)$. So, on the t_f line my trajectory can terminate. So, in this case naturally my t_f is specified, δt_f will be 0

and the coefficient has δx_f is arbitrary δx_f is arbitrary. So, the coefficient of δx_f is $\frac{\delta S}{\delta x} - \lambda'(t_f) = 0$.

So, this coefficient 0 this means I have a condition $\lambda(t_f) = \frac{\delta S}{\delta x}$ at t_f point. So, this will be my boundary condition in that case.

(Refer Slide Time: 09:01)

If free final time and the free final state free, so t_f and x_f are free. So, my trajectory can go anywhere. Again the 2 cases adjust here which we once we have the free final time and the free final state if both are independent means there is no relation between δt_f and δx_f . So, the coefficient of both will independently will be 0. So, $H + \frac{\delta S}{\delta t}$ will be 0, $\frac{\delta S}{\delta x} - \lambda'(t_f)$ at t_f point that will also be 0.

(Refer Slide Time: 09:46)

Different Types of Systems

5. Free-Final Time and Dependent Free-Final State System
If t_f and $x(t_f)$ are related such that $x(t_f)$ lies on a moving curve $\theta(t)$

$$\mathbf{x}(t_f) = \boldsymbol{\theta}(t_f) \quad \text{and} \quad \delta \mathbf{x}_f \approx \dot{\boldsymbol{\theta}}(t_f) \delta t_f.$$

Using the boundary condition, optimal condition becomes

$$\left[\left(\mathcal{H} + \frac{\partial S}{\partial t} \right)_* + \left(\frac{\partial S}{\partial \mathbf{x}} - \boldsymbol{\lambda}^*(t) \right)'_* \dot{\boldsymbol{\theta}}(t) \right]_{t_f} \delta t_f = 0.$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

But there may be the case that free final time and the dependent free final state system, as we have considered before let us say my trajectory terminate to a curve given by the theta t. So, this means we are considering a case, can I have the slide; we are considering the case that my final state is terminating to a curve theta t which is given by this curve.

(Refer Slide Time: 10:08)

So, at t_f point I have x of t_f equal to θ of t_f . So, at this point my x t_f is equal to θ of t_f . So, in this case I can approximate δx_f is θ dot of t_f into δt_f . So, if I am all approximate this, so I have a relation between δx_f and δt_f . I will

place this value δx_f in this given relation. So, here t_f and δx_f are related to each other I am replacing δx_f as $\dot{\theta}(t_f)$ and if I will club this my terminal condition comes out to be $H + \frac{\partial S}{\partial t} + \frac{\partial S}{\partial x} - \lambda^*$ at t_f equal to 0.

(Refer Slide Time: 11:40)

Different Types of Systems

Since t_f is free, δt_f is arbitrary and hence the coefficient of δt_f is zero

$$\left[\left(\mathcal{H} + \frac{\partial S}{\partial t} \right)_* + \left(\frac{\partial S}{\partial \mathbf{x}} - \lambda^*(t) \right)'_* \dot{\theta}(t) \right]_{t_f} = 0.$$

↓

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

δt_f is arbitrary, so the coefficient of this will be equal to 0 to get my final condition. So, in total we have discussed the 5 type of the system - the first one was the fixed final time and the fixed final state in which δt_f and δx_f both are 0, my second was the free final time and the fixed final state I have the fixed final is state, so δx_f will be 0. My third case is the fixed final time and free final state system. So, δt_f will be 0 and the condition you will get it here. The fourth and the fifth case we have the free final state and the free time, but in the first case both are independent. So, the coefficient of both δt_f and the δx_f are independently 0 and if it is dependent by a curve say $\theta(t)$ then my condition will be $H + \frac{\partial S}{\partial t} + \frac{\partial S}{\partial x} - \lambda^*$ at t_f equal to 0.

So, these end point conditions can be utilized if we are solving a problem. So, next we will take up an example and see how we can apply the Hamiltonian approach to solve a optimal control problem.

(Refer Slide Time: 13:25)

Consider a System

$$\begin{aligned}\dot{x}_1(t) &= x_2(t) \\ \dot{x}_2(t) &= u(t)\end{aligned}$$

Determine optimal $u(t)$ & $x(t)$ s.t.

$$PI \quad J = \frac{1}{2} \int_{t_0}^{t_f} u^2(t) dt \text{ is minimum.}$$

$$H = V(t) + \lambda' f(t)$$

$$H = \frac{1}{2} u^2 + [\lambda_1 \quad \lambda_2] \begin{bmatrix} x_2 \\ u \end{bmatrix}$$

$$H = \frac{1}{2} u^2 + \lambda_1 x_2 + \lambda_2 u$$

$$\frac{\partial H}{\partial u} = 0 \Rightarrow u + \lambda_2 = 0 \Rightarrow u = -\lambda_2$$

$$\begin{cases} V(t) = \frac{1}{2} u^2(t) \\ f_1(t) = x_2(t) \\ f_2(t) = u(t) \\ S(x(t_f), t_f) = 0 \\ \lambda = \begin{bmatrix} \lambda_1 \\ \lambda_2 \end{bmatrix} \end{cases}$$

Let first we will define; so we are given with consider a plant which is given as $\dot{x}_1 = x_2$ and $\dot{x}_2 = u$. So, our objective is determine optimal u and x such that performance index J equal to t_0 to t_f , $\int_{t_0}^{t_f} u^2 dt$ is minimum. So, our simple problem we are considering a simple plant $\dot{x}_1 = x_2$ and $\dot{x}_2 = u$ objective first a optimal u we will find, with the optimal u we say our is straight will also be the optimal. So, we are objective is to find the optimal u and optimal x which will minimize the J .

So, this problem we will solve using the Hamiltonian approach should define the Hamiltonian we have V plus λ prime f . So, in this case if we will see what we have V equal to integrant here half of u square t f_1 is x_2 t , f_2 is u t and if we will see the terminal cost S x t f , t f as no cost is given, so this value will be 0. So, based on this value I can define my H which is nothing but my half u square. So, I am dropping the t plus λ prime, what is the λ prime? It is a Lagrangian multiplier for each condition we will have the one Lagrangian multiplier. So, this is nothing but my λ_1 λ_2 or we can say I am defining my λ_1 , λ_2 .

So, my λ prime is λ_1 λ_2 ; f_1 f_2 which is nothing but my x_2 u . So, I can define my H as half u square plus $\lambda_1 x_2$ plus $\lambda_2 u$. So, here this H is defined as this equation. What is my objective to solve this? Using this 4 equation. So, my control equation is $\frac{\partial H}{\partial u} = 0$. So, first I will find out the control. So, first step I take $\frac{\partial H}{\partial u} = 0$ if I will differentiate H with respect to u . So, my

first step u is here. So, this is nothing but u, second term independent of u, third term is plus lambda 2 equal to 0. So, this will give me nothing but u equal to lambda 2. So, t both the side we are dropping out.

So, we can say u equal to lambda 2 with the given value of the H now we write the other equations. So, I keep my; this equation with me. So, my second equation is my state equation which is giving del H by del lambda equal to x dot t.

(Refer Slide Time: 19:25)

$$\begin{aligned} \dot{x}(t) &= \left(\frac{\partial H}{\partial \lambda} \right)_* \\ H^* &= \frac{1}{2} \lambda_2^2 + \lambda_1 x_2 - \lambda_2^2 \\ &= \lambda_1 x_2 - \frac{1}{2} \lambda_2^2 \\ \dot{x}_1(t) &= \left(\frac{\partial H}{\partial \lambda_1} \right)_* = x_2 \\ \dot{x}_2(t) &= \left(\frac{\partial H}{\partial \lambda_2} \right)_* = -\lambda_2 \\ \text{State} \rightarrow \dot{\lambda}(t) &= - \left(\frac{\partial H}{\partial x} \right)_* \\ \dot{\lambda}_1(t) &= - \left(\frac{\partial H}{\partial x_1} \right)_* = 0 \\ \dot{\lambda}_2(t) &= - \left(\frac{\partial H}{\partial x_2} \right)_* = -\lambda_1 \end{aligned}$$

$$\begin{aligned} x_1^* &= x_2 \\ x_2^* &= -\lambda_2 \\ \dot{\lambda}_1 &= 0 \\ \dot{\lambda}_2 &= -\lambda_1 \end{aligned}$$

So, x dot t we are taking as del H by del lambda at optimal point, optimal point means H we are finding at the optimal. So, u is sorry; in this case my u is not lambda 2, but this is u equal to minus lambda 2. If I will replace my u in this, so I can write my H star is 1 by 2 u, the optimal value of the u is minus lambda 2, so minus, this is nothing but half of lambda square plus lambda 1 x 2 minus lambda 2 into u. So, this is minus lambda square. So, my optimal H is nothing but lambda 1 x 2 sorry; minus 1 by 2 lambda 2 is square.

So, on this what is my optimal a state x? So, x 1 dot t is del H by del lambda 1 if I will take this del H by del lambda 1 because x is a vector of x 1 and x 2. So, this is del H by del lambda 1 is my x 1 del H by del lambda 2 is my x 2. So, del H by del lambda 1 if I will take, so this is nothing but x 2 and x 2 dot of t is del H by del lambda 2 at optimal point and this is in this case minus lambda 2.

So, my \dot{x}_1 is x_2 \dot{x}_2 is minus lambda 2 similarly now we can go. So, now, we write the costate equation is lambda dot t S minus del H by del x. So, my costate equation is lambda dot t as minus del H by del x for optimal value. So, what we have to do. So, this my optimal H is this, so del H by del x. So, again lambda is a vector of lambda 1 lambda 2. So, we will write lambda 1 dot t as minus del H by del x 1, lambda 1 del H by del x 1. With respect to x 1 if we will differentiate this what I will get there is no x 1 term, so this is 0. Similarly we have lambda 2 dot t minus del H by del x 2, what we will get by this? With respect to x 2 we are differentiating. So, we have only the lambda 2. So, this is, so lambda 2 t is nothing but lambda 1.

So, from the a state and the costate equation we will have the state equation is \dot{x}_1 as x_2 and \dot{x}_2 as minus lambda 2 which we are getting by these 2 equations, and the costate equation lambda 1 dot equal to 0 and lambda 2 dot equal to lambda 1 sorry; we have did a mistake del H by del x 2 is this, this is lambda 1 with negative sign. So, this will be minus lambda 1. So, my this equation is nothing, but \dot{x}_2 equal to minus lambda 1 because we have miss this negative term initial to represent this. So, now, these equations we have to solve simultaneously, how we can solve this equation?

(Refer Slide Time: 25:56)

Handwritten mathematical derivation showing the solution of costate equations and boundary conditions:

$$\begin{aligned} \dot{\lambda}_1 = 0 &\Rightarrow \lambda_1^*(t) = C_1 \rightarrow \textcircled{1} & \dot{x}_1 = x_2 \\ \dot{\lambda}_2 = -\lambda_1 &\Rightarrow \lambda_2^*(t) = -t + C_2 \rightarrow \textcircled{2} & \dot{x}_2 = -\lambda_2 \\ \dot{x}_2 = t - C_2 &\Rightarrow x_2^*(t) = \frac{1}{2}t^2 - C_2t + C_3 \rightarrow \textcircled{3} & \dot{\lambda}_1 = 0 \\ \dot{x}_1 = \frac{1}{2}t^2 - C_2t + C_3 &\Rightarrow x_1^*(t) = \frac{1}{6}t^3 - \frac{1}{2}C_2t^2 + C_3t + C_4 \rightarrow \textcircled{4} & \dot{\lambda}_2 = -\lambda_1 \end{aligned}$$

Let us consider the boundary conditions are given as

$$x(0) = [x_1(0) \ x_2(0)]' = [1 \ 2]'; \quad x_1(2) = 0$$

$x_1(0) = 1$ from Eqn (4) $x_1(0) = 1 = C_4 \Rightarrow C_4 = 1$ $x_2(2)$ is free
 $x_2(0) = 2$ from Eqn (3) $2 = C_3 \Rightarrow C_3 = 2$ t_+ is specified
 $x_1(2) = 0$ from Eqn (4) $0 = \frac{8}{6}C_1 - 2C_2 + 5$ $x_2(t_+)$ is free

So, we take first equation lambda 1 dot equal to 0, so solution of this as we now, this solution gives us lambda 1 t equal to let say C 1 where C 1 will be a constant if lambda 1 t is C 1 we have lambda 2 dot is minus lambda 1 which is nothing, but C 1. So, this

means $\lambda_2 t$ is $\min C_1 t + C_2$. So, this will be my $\lambda_2 t$. Say from these equations \dot{x}_1 is x_2 , \dot{x}_2 is $-\lambda_2$. So, what we can write? Next equation we can take as x_2 which is $-\lambda_2$ means this is $C_1 t - C_2$. So, this is \dot{x}_2 if I will simplify this I will get $x_2 t$ as, so $\frac{1}{2} C_1 t^2 - C_2 t + C_3$. So, this will be my x_2 dot, and if I will have next equation is \dot{x}_1 as x_2 which is $\frac{1}{2} C_1 t^2 - C_2 t + C_3$. So, this will give me my $x_1 t$ S just to integrate this $\frac{1}{6} C_1 t^3 - \frac{1}{2} C_2 t^2 + C_3 t + C_4$. So, I have $\lambda_1 t$, $\lambda_2 t$, $x_2 t$, $x_1 t$ and we can note this these all are my nothing, but optimal values because they are determined on the optimal u .

So, next is these equations these set of equations we got simply by solving the first 3 equations. Now to determine the value of all the constant $C_1 C_2 C_3 C_4$ we have to utilize the boundary conditions, and boundary condition will depend what type of the case we will have. Like you will consider one case here also though these conditions can vary, let us consider the boundary conditions are given as, let we are given with x_0 which is nothing but my $x_1 0$, $x_2 0$ transpose is equal to $\begin{bmatrix} 1 \\ 2 \end{bmatrix}$ the another condition is given as let $x_1 2$ equal to 0 and $x_2 2$ is free. So, I am given with these conditions like $x_1 0$ equal to 1 I have $x_1 t$ given here. So, what this equation give me? So, let us gives the name equation 1 equation 2 let say this is 3 and this is 4.

So, $x_1 0$ equal to 1; we can have from equation 4 what we will have? $x_1 0$ equal to 1 and this equal to t equal to 0 nothing, but my C_4 this implies C_4 equal to 1. Now $x_2 0$ equal to 2 we can take the equation 3, from equation 3 we have because $x_2 0$ is 2 equal to and this case t is 0. So, this all will be 0 we are left with the C_3 . So, C_3 equal to 2. So, we are evaluated the 2 constants C_3 and C_4 . Now my another condition here is $x_1 2$ equal to 0 means t is fixed and see for x_1 again a fixed condition is given, $x_1 2$ equal to 0.

So, again from 4 - $x_1 2$ is 0. So, again we consider the equation 4 what actually we will have? My t equal to 2, so 0 equal to I am taken the t S 2, C_1 is unknown. So, this is nothing but $\frac{1}{6} C_1 t^3 - \frac{1}{2} C_2 t^2 + C_3 t + C_4$. So, $\frac{1}{6} C_1 t^3 - \frac{1}{2} C_2 t^2 + C_3 t + C_4$ is 1 plus 5. So, I get a equation is $\frac{1}{6} C_1 t^3 - \frac{1}{2} C_2 t^2 + C_3 t + C_4 = 5$.

Again I need one more equation because I cannot find $C_1 C_2$ from this equation. So, I will use this which is given $x_2 2$ is free, this means t is specified and $x_2 t$ is free.

So, which condition I will use from my case? My condition is I have the fixed final time and the free final state and that is applicable to my second state for x_2 only, my condition is $\lambda_2(t_f) = \frac{\partial S}{\partial x_2}$.

(Refer Slide Time: 35:06)

$\lambda_2(t_f) = \left(\frac{\partial S}{\partial x_2} \right) \Big|_{t=t_f} = 0$

$\lambda_2(t) = -C_1 t + C_2$

$\lambda_2(2) = -2C_1 + C_2 = 0 \rightarrow \textcircled{6}$

Solve $\textcircled{5}$ and $\textcircled{6}$ to get C_1 & C_2 .

$C_1 = 15/8; C_2 = 15/4$

$x_1(0) = 1$ from Eqn (4) $x_1(0) = 1 = C_4 \Rightarrow C_4 = 1$ $x_2(2)$ is free

$x_2(0) = 2$ from Eqn (3) $2 = C_3 \Rightarrow C_3 = 2$ t_f is specified

$x_1(2) = 0$ from Eqn (4) $0 = \frac{8}{8}C_1 - 2C_2 + 5 \rightarrow \textcircled{5}$ $x_2(t_f)$ is free

So, I can write $\lambda_2(t_f) = \frac{\partial S}{\partial x_2}$. So, $\lambda_2(t_f) = \frac{\partial S}{\partial x_2}$ at t equal to t_f point as you can see we have considered the S to be 0. So, this is nothing but this will give me equal to 0. So, my $\lambda_2(t_f)$ is 0 this means my I will have equation number 2 which will have $\lambda_2(t)$ is minus $C_1 t$ plus C_2 . So, t_f is 2, so I am writing $\lambda_2(2)$ which is my t_f minus $2C_1$ plus C_2 and $\lambda_2(2)$ value is nothing but 0. So, 4 equation we have, so I have this equation number 5 this equation number 6. So, equation 5 and 6 can be solve 2 find the value of C_1 and C_2 which gives me, so solve 5 and 6 to get C_1 and C_2 .

So, what actually we are getting? So, this gives me C_1 equal to 15 by 8 and C_2 equal to 15 by 4. So, now, I have all my C_1, C_2, C_3, C_4 as C_1 equal to 15 by 8, C_2 equal to 15 by 4, C_3 equal to 2 and C_4 equal to 1. So, with this C_1, C_2, C_3, C_4 are calculated utilizing the endpoint condition. And now I can represent my all optimal values in terms of the C_1, C_2, C_3 and C_4 .

(Refer Slide Time: 38:40)

$$\begin{aligned}
 u^*(t) &= -\lambda_2(t) = -c_1 t + c_2 \\
 \checkmark u^*(t) &= -\frac{15}{8}t + \frac{15}{4} \\
 \checkmark x_1^*(t) &= \frac{1}{6}c_1 t^3 - \frac{1}{2}c_2 t^2 + c_3 t + c_4 \\
 \checkmark x_2^*(t) &= \frac{1}{2}c_1 t^2 - c_2 t + c_3
 \end{aligned}$$

$$\begin{aligned}
 c_1 &= 15/8 \\
 c_2 &= 15/4 \\
 c_3 &= 2 \\
 c_4 &= 1
 \end{aligned}$$

So, what I will have? My optimal u is $u^*(t)$, so $u^*(t) = -\lambda_2(t)$ and $\lambda_2(t)$ is nothing but $-c_1 t + c_2$. So, my optimal u is nothing but $-\frac{15}{8}t + \frac{15}{4}$, and $x_1^*(t)$ is given as $\frac{1}{6}c_1 t^3 - \frac{1}{2}c_2 t^2 + c_3 t + c_4$. So, I can place this value to get the optimal x_1 and similarly optimal x_2 is given as $\frac{1}{2}c_1 t^2 - c_2 t + c_3$. So, this is my optimal control relation and these are the optimal states. So, this example gives the application of the Hamiltonian approach to determine the optimal control and the optimal states of a given system.

Now, depending upon the final conditions my values of c_1, c_2, c_3, c_4 can change. So, different boundary condition can be taken as we have discussed the 4 cases we will end of with the different type of the conditions. Like the case 1 2 3 4 these equations can be utilized to determine the coefficient. So, if I will summarize my approach I have to solve first the control equation to get the optimal control then get the state and the costate equation, solve these equation with optimal control value in terms of the c_1, c_2, c_3, c_4 or whatever be the constants are there and these constants can be determined utilizing the initial condition $t=0$ and $x(t=0)$ as well as the final conditions which may appear in this 5 phones.

So, I stop my; this lecture here and in the next class we will further see the application of the Hamiltonian approach to determine the journal case of a linear control system.

Thank you very much.
