Lecture - 15
Linear Quadratic Optimal Control Systems

Welcome to all. So, today our class is on linear quadratic optimal control system. In the previous class we completed our discussion on variational application, variational calculus application to the optimal control system and in this we have develop an approach in which in terms of the Hamiltonian we can represent our system where Hamiltonian is defined as v plus λ prime f .

(Refer Slide Time: 01:07)

Variational Approach to Optimal Control Systems

In terms of Hamiltonian H^*

The Control Equation $\left(\frac{\partial \mathcal{H}}{\partial \mathbf{u}}\right)_* = 0$

The State Equation $\left(\frac{\partial \mathcal{H}}{\partial \lambda}\right)_* = \dot{\mathbf{x}}^*(t)$

The Costate Equation $\left(\frac{\partial \mathcal{H}}{\partial \mathbf{x}}\right)_* = -\dot{\lambda}^*(t)$

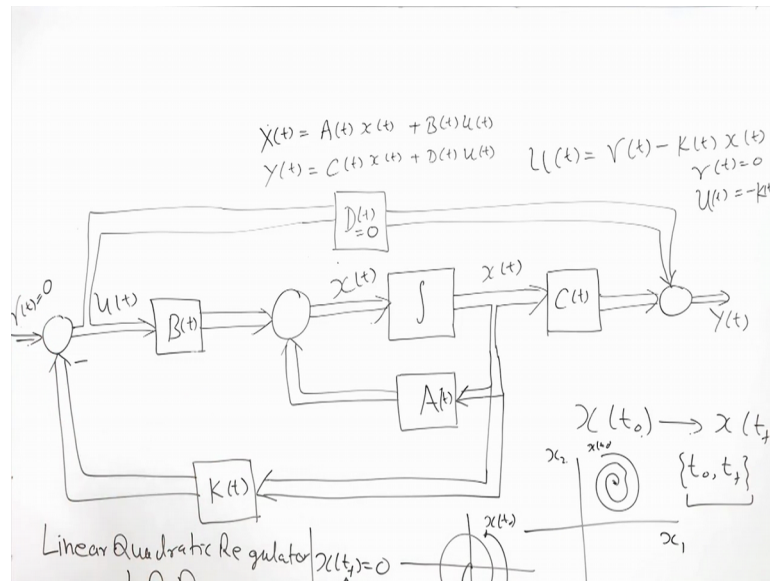

The Boundary Condition $\left[\mathcal{H}^* + \frac{\partial S}{\partial t}\right]_{t_f} \delta t_f + \left[\left(\frac{\partial S}{\partial \mathbf{x}}\right)_* - \lambda^*(t)\right]'_{t_f} \delta \mathbf{x}_f = 0$

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

And our equations can be represented as the control equation $\frac{\partial H}{\partial u} = 0$, $\frac{\partial H}{\partial \lambda} = \dot{x}$ which is my state equation, $\frac{\partial H}{\partial x} = -\dot{\lambda}$ which is my costate equation. These equation can be solved and the constant or the final solution can be determined utilizing the different boundary condition which comes up from the last equation.

So, now, application of this we will see to the linear quadratic optimal control system. As we all know what is a linear system.

(Refer Slide Time: 01:58)

Any linear system in term in the study space we can represent it as $\dot{x} = Ax + Bu$ and point t we can represent as $y = Cx + Du$. So, objective here for the given linear system we have to develop a control law, control law are normally we take as $u = -Kx$; we say this as $u = -Kx$, so that we can control the system. And then the what condition we can control the system? If my system is completely controllable then I can control the system means I can transfer the state of the system from a given initial condition to some final condition in a given time, so that is my objective.

So, how to implement this control? Now this system I can represent in terms of the block diagram as sorry till this as B , this is integral, I take this as A and further if I will extent. So, this is my \dot{x} , this is x . So, $\dot{x} = Ax + Bu$, this I will take as u and let us say this as my reference $r = 0$ and $y = Cx + Du$ will and as we have seeing if I will take this u I can pick up from here with D , so this will be my y . So, $y = Cx + Du$.

So, this system I can represent in by this block diagram, objective here is to implement the control law $u = -Kx$. So, in this case let first we consider $r = 0$ then control law we can implement as feeding back the states as a negative feedback to r . So, if I will consider this case let us first case $u = r - Kx$. So, this is a journal control, state feedback controller problem where we have to design the K such

that I can transfer my state from $x(t_0)$ to some $x(t_f)$ in a specified interval of time t_0 to t_f . So, in this interval I want to transfer my state from initially state to final state for which we have to design a control law which may be $R(t) - K(t)x(t)$. So, this is my control problem.

Now how to get the value of the $K(t)$ there are the main approaches in advance control system we know we have the pole placement technique by which this $K(t)$ can be determined. Now as if we will make $R(t)$ to 0 what is the meaning this? My reference is 0, so if $R(t)$ is 0 so my control law is nothing, but $u(t)$ equal to minus $K(t)x(t)$. So, this problem will become the regulator problem. So, in this we will, we do not have any change in the set point my set point is fixed, my system is subjected to the disturbance and with this disturbance system will again return to its operating point. So, that is called my regulator problem if $R(t)$ will become 0.

So, I can also set let us say I have the 2 states x_1, x_2 and any operating point. So, let my system is start with $x(t_0)$ from here. So, after the disturbance it will return to the same point which is my operating point. So, this operating point if my $R(t)$ is 0 I can take this operating point at the origin by simply using my shifting the origin principle. So, anytime I can shift my origin to this point. So, my problem here will be my from $x(t_0)$ I have to transfer my state to $x(t_f)$ equal to 0 where t_f is specified. So, this is called my linear quadratic regulator problem which we call linear quadratic regulator, very famously we write this as this is my LQR problem.

(Refer Slide Time: 12:34)

Linear Quadratic Optimal Control Systems

Consider a linear, time-varying (LTV) system

$$\dot{\mathbf{x}}(t) = \mathbf{A}(t)\mathbf{x}(t) + \mathbf{B}(t)\mathbf{u}(t)$$
$$\mathbf{y}(t) = \mathbf{C}(t)\mathbf{x}(t)$$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, if you will look at this we are defining a system as $\dot{x} = Ax + Bu$ and $y = Cx$. In general we can consider the D matrix to be 0. This means if there is a direct influence on the y , in most of the physical systems I have $D = 0$. So, we are representing our system simply as $y = Cx$. So, this is my linear time-varying system because A , B , and C all are functions of time we are varying with time. So, initially we are considering a general linear time-varying system. The objective is to keep the state $x(t)$ near 0. So, this is a state regulator system.

(Refer Slide Time: 13:23)

Linear Quadratic Optimal Control Systems

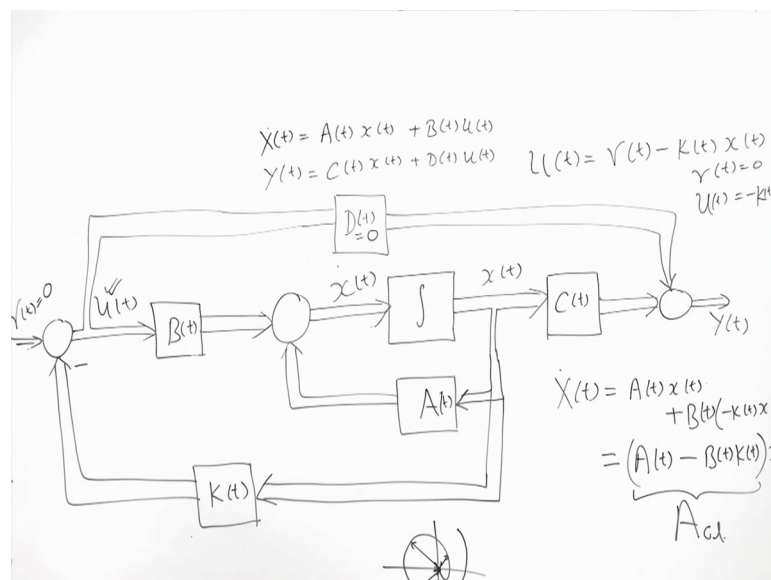

- The objective is to keep the state $x(t)$ near zero: State Regulator System.
- Obtain a control $u(t)$ which takes the plant from a nonzero state to zero state and minimize J .
- The plant is subjected to unwanted disturbances that perturb the state.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

We want to obtain the control $u(t)$ which takes the plant for nonzero initial state to the 0 state and simultaneously minimize the performance index. In, as we are reaching transferring our nonzero state to the 0 state, so this means my $R(t)$ is 0 and the plant is subjected to the unwanted disturbance that part of my system.

So, this regulator problem in this regulator problem our objective is to find the value of the $K(t)$ and that is particularly optimally. If we have in a regulator u equal to $K(t)x(t)$ as we said we can find this control law using many other approach one of the approach is the pole placement technique in which we specify where my closed loop system pole will lie. So, in LQR problem I will keep the system.

(Refer Slide Time: 14:57)

So, as u equal to minus $K(t)x(t)$ if I will place this, so $\dot{x}(t)$ will be $A(t)x(t) + B(t)u(t)$ and in place of the u I am placing my minus $K(t)x(t)$ so I feel combined the x term. So, my closed loop system will be $A(t) - B(t)K(t)$ and this whole is $\dot{x}(t)$. And this whole I can represent as my closed loop matrix.

So, I can say this $A(t)$ is an open loop matrix and A_{cl} is my closed loop matrix. So, after implementing the control law my objective here is whatever be the condition of the $A(t)$ this A_{cl} a closed loop matrix will be a stable matrix and have the desired performance characteristics, because in a linear system matrix A is my system matrix which completely governs the performance of my system. So, using the pole placement technique what we want, my closed loop system will have the desired poles which is

already specified we are about to shift my eigenvalues of A in A c l means whatever be the eigenvalues of A in closed loop system I will shift my eigenvalues from, I will shift my eigenvalues to the desired location.

But in this case we cannot guarantee whether my eigenvalues are shifted optimally or not. So, that is why we have the state regulator problem to be solved optimally. So, that is why we are saying we our objective in linear quadratic optimal control system is to determine the u which will take the plant from nonzero to 0 state and simultaneously minimizes a performance index performance index.

(Refer Slide Time: 17:57)

Linear Quadratic Optimal Control Systems

The Performance Index (PI)

$$\begin{aligned}
 J(\mathbf{u}) &= J(\mathbf{x}(t_0), \mathbf{u}(t), t_0) \\
 &= \frac{1}{2} \mathbf{x}'(t_f) \mathbf{F}(t_f) \mathbf{x}(t_f) \\
 &\quad + \frac{1}{2} \int_{t_0}^{t_f} [\mathbf{x}'(t) \mathbf{Q}(t) \mathbf{x}(t) + \mathbf{u}'(t) \mathbf{R}(t) \mathbf{u}(t)] dt \\
 &= \frac{1}{2} \mathbf{x}'(t_f) \mathbf{F}(t_f) \mathbf{x}(t_f) \\
 &\quad + \frac{1}{2} \int_{t_0}^{t_f} \begin{bmatrix} \mathbf{x}'(t) & \mathbf{u}'(t) \end{bmatrix} \begin{bmatrix} \mathbf{Q}(t) & \mathbf{0} \\ \mathbf{0} & \mathbf{R}(t) \end{bmatrix} \begin{bmatrix} \mathbf{x}(t) \\ \mathbf{u}(t) \end{bmatrix} dt
 \end{aligned}$$

Here we take as $\frac{1}{2} \mathbf{x}'(t_f) \mathbf{F}(t_f) \mathbf{x}(t_f) + \frac{1}{2} \int_{t_0}^{t_f} [\mathbf{x}'(t) \mathbf{Q}(t) \mathbf{x}(t) + \mathbf{u}'(t) \mathbf{R}(t) \mathbf{u}(t)] dt$. So, because my performance index is quadratic in nature we call this problem a quadratic optimal control problem. So, if for a linear system this quadratic performance index we can select what this performance index will have, the first term $\frac{1}{2} \mathbf{x}'(t_f) \mathbf{F}(t_f) \mathbf{x}(t_f)$ represent my terminal cost which will depend on my what is my final state plus half of $\mathbf{x}'(t_f) \mathbf{F}(t_f) \mathbf{x}(t_f)$. Now what actually is the \mathbf{x} ? In quality case if we consider my final state to it origin so this and this is my and initially state. So, at n instant of the time this is representing nothing, but the error in the state.

So, at n instant this is representing because my desire is 0 minus whatever is the state at that particular time. So, desired state minus the actual state giving me nothing, but the error and the desired state is 0 so this I am getting nothing, but error. So, the first part of

integral performance index $x^T Q x$ this nothing but used to minimize the error and second $u^T R u$ is used to minimize the control effort which we have taken as the energy. So, this $u^T R u$ is nothing but to minimize the control effort, minimize the error, minimize the terminal cost

So, we have selected the performance index which is quadratic in nature, which is minimizing by terminal cost, which is minimizing my error, which is minimizing my control efforts and matrix form we can write this as $x^T Q x + u^T R u + F(t)$, Q and R , x and u . So, in this performance index we have taken as the F of t , Q of t , R of t .

(Refer Slide Time: 20:50)

Linear Quadratic Optimal Control Systems

- The weighted matrices $Q(t)$, $R(t)$, and $F(t)$ are symmetric
- $F(t)$ should be positive semidefinite
- $Q(t)$ must be positive semidefinite
- The matrix $R(t)$ should be positive definite
- There are no constraints on the control $u(t)$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

What these matrices represent here? These are the weighted matrix Q t R t and F t are they are symmetric in nature normally F t is positive semidefinite Q t is also positive semidefinite, but the matrix R t should be a positive definite. And there is no constraint are considered in this particular case. F is positive semidefinite means some of the state, weight given to some of the final state may be 0.

Similarly, weight on the state at any instant any state I can make it to 0, but anytime I cannot make any control to be 0 because all my system is controlled by the u t . So, always the certain rates I have to give to all my controls. So, that is why we are selected R to be the positive definite. So, we will take F positive semi definite, Q as positive semi definite, R to be the positive definite and we are not considering any constraint on the control. So, I have my plant which is given as \dot{x} is A x plus B u , I have my

performance index given as the J and in this problem we have to find our objective is to find the u which will minimize the performance index as well as satisfy the plant condition.

So, if you will recall this was my variational approach to the control problem. So, we can directly use my Hamiltonian approach to solve this problem. So, we have to use equation, control equation, state equation and the costate equation to solve this linear quadratic optimal problem.

(Refer Slide Time: 23:10)

Linear Quadratic Optimal Control Systems

Formulate the Hamiltonian as

$$\mathcal{H}(\mathbf{x}(t), \mathbf{u}(t), \boldsymbol{\lambda}(t)) = \frac{1}{2} \mathbf{x}'(t) \mathbf{Q}(t) \mathbf{x}(t) + \frac{1}{2} \mathbf{u}'(t) \mathbf{R}(t) \mathbf{u}(t) + \boldsymbol{\lambda}'(t) [\mathbf{A}(t) \mathbf{x}(t) + \mathbf{B}(t) \mathbf{u}(t)]$$

where, $\boldsymbol{\lambda}(t)$ is the costate vector of n th order

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

(Refer Slide Time: 23:18)

$$\mathcal{H}(t) = \frac{1}{2} (\mathbf{x}'(t) \mathbf{Q}(t) \mathbf{x}(t) + \mathbf{u}'(t) \mathbf{R}(t) \mathbf{u}(t)) + \boldsymbol{\lambda}'(t) [\mathbf{A}(t) \mathbf{x}(t) + \mathbf{B}(t) \mathbf{u}(t)]$$

Control $\rightarrow \frac{\partial \mathcal{H}(t)}{\partial \mathbf{u}} = \mathbf{R}(t) \mathbf{u}(t) + \mathbf{B}'(t) \boldsymbol{\lambda}(t) = 0$

$$\mathbf{u}(t) = -\mathbf{R}^{-1}(t) \mathbf{B}'(t) \boldsymbol{\lambda}(t)$$

State $\rightarrow \dot{\mathbf{x}}(t) = \left(\frac{\partial \mathcal{H}(t)}{\partial \mathbf{x}} \right)_{*} = \mathbf{A}(t) \mathbf{x}(t) + \mathbf{B}(t) \mathbf{u}(t)$

$$\dot{\mathbf{x}}(t) = \mathbf{A}(t) \mathbf{x}(t) - \mathbf{B}(t) \mathbf{R}^{-1}(t) \mathbf{B}'(t) \boldsymbol{\lambda}(t)$$

Costate $\rightarrow \dot{\boldsymbol{\lambda}}(t) = -\left(\frac{\partial \mathcal{H}}{\partial \boldsymbol{\lambda}} \right) = -\mathbf{Q}(t) \mathbf{x}(t) - \mathbf{A}'(t) \boldsymbol{\lambda}(t)$

So, my first steps to write the Hamiltonian H which is equal to my v plus lambda prime f . So, what is my v ? v is nothing, but my quadratic function which is $x^T Q x + u^T R u$ and this whole we are dividing I taking as 1 by 2. This 1 by 2 is used to only to simplify the calculation which is come in the later part. This is my v plus lambda prime t into F . What is my f ? Here \dot{x} equal to $A x$ this is $A^T x + B^T u$.

So, I am taking this as my H which is half $x^T Q x$ plus half $u^T R u$ plus lambda prime $A^T x + B^T u$. Lambda t is my Lagrangian multiplier, here we will take as a costate vector because my system is of the n th order therefore, the order of my lambda will also be of the n th. So, lambda is a n th order costate vector.

My first equation is $\frac{\partial H}{\partial u} = 0$. So, in the given H if I will differentiate this H with respect to u this is this time is a function of u and in the second my this lambda prime $B^T u$ is a function of u . So, their differentiation if the first time will give me 0 second because $u^T R u$ this will be cancelled out so this will given me as $R^T u$ and if I will differentiate this plus $B^T \lambda$. So, differentiation of $\frac{\partial H}{\partial u}$ is $R^T u + B^T \lambda$ and this must be equal to 0. So, therefore, I can directly write my u to be minus $R^{-1} B^T \lambda$. So, we got this equation has u equal to minus $R^{-1} B^T \lambda$.

(Refer Slide Time: 27:12)

Linear Quadratic Optimal Control Systems

Obtain the optimal control $u^*(t)$ using the control relation

$$\frac{\partial \mathcal{H}}{\partial \mathbf{u}} = 0 \longrightarrow \mathbf{R}(t)\mathbf{u}^*(t) + \mathbf{B}'(t)\boldsymbol{\lambda}^*(t) = 0$$

$$\mathbf{u}^*(t) = -\mathbf{R}^{-1}(t)\mathbf{B}'(t)\boldsymbol{\lambda}^*(t)$$

4

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

(Refer Slide Time: 27:15)

Linear Quadratic Optimal Control Systems

The state and costate equations

$$\dot{\mathbf{x}}^*(t) = + \left(\frac{\partial \mathcal{H}}{\partial \mathbf{x}} \right)_* \quad \text{leads to} \quad \dot{\mathbf{x}}^*(t) = \mathbf{A}(t)\mathbf{x}^*(t) + \mathbf{B}(t)\mathbf{u}^*(t)$$

$$\dot{\boldsymbol{\lambda}}^*(t) = - \left(\frac{\partial \mathcal{H}}{\partial \boldsymbol{\lambda}} \right)_* \quad \text{leads to} \quad \dot{\boldsymbol{\lambda}}^*(t) = -\mathbf{Q}(t)\mathbf{x}^*(t) - \mathbf{A}'(t)\boldsymbol{\lambda}^*(t)$$

The canonical system (also called Hamiltonian system) of equations

$$\begin{bmatrix} \dot{\mathbf{x}}^*(t) \\ \dot{\boldsymbol{\lambda}}^*(t) \end{bmatrix} = \begin{bmatrix} \mathbf{A}(t) & -\mathbf{E}(t) \\ -\mathbf{Q}(t) & -\mathbf{A}'(t) \end{bmatrix} \begin{bmatrix} \mathbf{x}^*(t) \\ \boldsymbol{\lambda}^*(t) \end{bmatrix}$$

where

$$\mathbf{E}(t) = \mathbf{B}(t)\mathbf{R}^{-1}(t)\mathbf{B}'(t).$$

Then I have to write my state and the costate equation. State equation is $\dot{\mathbf{x}}$ equal to $\frac{\partial \mathcal{H}}{\partial \mathbf{x}}$. So, $\frac{\partial \mathcal{H}}{\partial \mathbf{x}}$ if we will take, so this is my control state equation is $\dot{\mathbf{x}} = \frac{\partial \mathcal{H}}{\partial \mathbf{x}}$ and what is the value of this.

So, the first term is independent of my $\boldsymbol{\lambda}$. So, this all will not give me anything and this will give me with respect to $\boldsymbol{\lambda}$. So, this is nothing but my $\mathbf{A} \mathbf{x} + \mathbf{B} \mathbf{u}$ I am getting and \mathbf{u} is we already got \mathbf{R}^{-1} this, so this will be my optimal value. So, this is nothing, but my $\mathbf{A} \mathbf{x}$. So, I can say this will be my optimally state as $\mathbf{A} \mathbf{x} - \mathbf{B} \mathbf{R}^{-1} \mathbf{B}' \boldsymbol{\lambda}$. So, this will be my state equation costate equation $\dot{\boldsymbol{\lambda}} = -\frac{\partial \mathcal{H}}{\partial \boldsymbol{\lambda}}$ is my nothing but $\dot{\boldsymbol{\lambda}}$.

So, my first term is a function of \mathbf{x} . So, this is giving me due to this negative sign $\mathbf{Q} \mathbf{x}$ and another \mathbf{x} dependent term is $\boldsymbol{\lambda}' \mathbf{A} \mathbf{x}$ I have to differentiate this term, if I will differentiate this term we will get minus $\mathbf{A}' \boldsymbol{\lambda}$. So, here prime represent my transpose. So, we are saying this is the \mathbf{A} transpose and \mathbf{B} transpose. So, I got the 2 equations as $\dot{\mathbf{x}} = \mathbf{A} \mathbf{x} - \mathbf{B} \mathbf{R}^{-1} \mathbf{B}' \boldsymbol{\lambda}$ and the costate equation is $\dot{\boldsymbol{\lambda}} = -\mathbf{Q} \mathbf{x} - \mathbf{A}' \boldsymbol{\lambda}$.

So, these 2 equations we are getting here and this equation I can write in this particular form which is called the Hamiltonian system.

(Refer Slide Time: 31:47)

$$\begin{bmatrix} \dot{x}(t) \\ \dot{\lambda}(t) \end{bmatrix} = \begin{bmatrix} A(t) & -B(t)R^{-1}(t)B'(t) \\ -Q(t) & -A'(t) \end{bmatrix} \begin{bmatrix} x(t) \\ \lambda(t) \end{bmatrix}$$

$$\left[\left(\frac{\partial S}{\partial x} \right)_{*} \Big|_{t=t_f} - \lambda^*(t_f) \right] = 0$$

$$\lambda(t_f) = \left(\frac{\partial S}{\partial x} \right)_{*} \Big|_{t=t_f} = \frac{\partial}{\partial x(t_f)} \left(\frac{1}{2} x'(t_f) F(t_f) x(t_f) \right)$$

$$\lambda(t_f) = F(t_f) x(t_f)$$

So, I am writing a state and the costate equation in terms of a matrix form some clubbing \dot{x} and $\dot{\lambda}$ is $\begin{bmatrix} \dot{x} \\ \dot{\lambda} \end{bmatrix}$ is $\begin{bmatrix} A & -B R^{-1} B' \\ -Q & -A' \end{bmatrix} \begin{bmatrix} x \\ \lambda \end{bmatrix}$. So, with the $\begin{bmatrix} \dot{x} \\ \dot{\lambda} \end{bmatrix}$ I will have the $\begin{bmatrix} A & -B R^{-1} B' \\ -Q & -A' \end{bmatrix}$ matrix. So, I got this equation where I am representing as $\begin{bmatrix} A & -B R^{-1} B' \\ -Q & -A' \end{bmatrix}$.

So, using this we have converted this into the Hamiltonian system. So, this is giving me the state and the costate equation which is converting my system into the Hamiltonian system.

(Refer Slide Time: 33:20)

Linear Quadratic Optimal Control Systems

The boundary condition is given by

$$\left[\mathcal{H}^* + \frac{\partial S}{\partial t} \right]_{t_f} \delta t_f + \left[\left(\frac{\partial S}{\partial x} \right)_{*} - \lambda^*(t_f) \right]_{t_f} \delta x_f = 0$$

t_f is specified i.e. $\delta t_f = 0$ and $x(t_f)$ is free i.e. δx_f is arbitrary.

Therefore, the coefficient of δx_f becomes zero

$$\begin{aligned} \lambda^*(t_f) &= \left(\frac{\partial S}{\partial x(t_f)} \right)_{*} \\ &= \frac{\partial \left[\frac{1}{2} x'(t_f) F(t_f) x(t_f) \right]}{\partial x(t_f)} = F(t_f) x^*(t_f) \end{aligned}$$

Next is my boundary condition here, the general boundary condition given as $H + \frac{\partial S}{\partial t} + \frac{\partial S}{\partial x} \dot{x} - \lambda^T (\dot{x} - f) = 0$. Say in this case if you will recall what is my problem, my problem is to transfer the state from initial state which is $x(t_0)$ means t_0 and $x(t_0)$ both are given to me to the final state in a specified time this will the t_f is a specified. If t_f is a specified, so this $\frac{\partial S}{\partial t}$ will be 0, so I have left only with the $\frac{\partial S}{\partial x} \dot{x} - \lambda^T \dot{x}$ at t_f point \dot{x} . So, if I will consider my $\frac{\partial S}{\partial t}$ to be 0 I am left with the condition $\frac{\partial S}{\partial x} \dot{x}$ at t equal to t_f point minus $\lambda^T \dot{x}$ say $\lambda^T \dot{x}$ at the t_f point that must be equal to 0.

So, my $\lambda^T \dot{x}$ is nothing but $\frac{\partial S}{\partial x} \dot{x}$ at t equal to t_f point. Now if you will see what is my terminal cost, my terminal cost is $\frac{1}{2} x^T(t_f) F x(t_f) + x^T(t_f) \phi$, $x^T(t_f) \phi$ and this is nothing but my S , S equal to this. So, this means if I have to differentiate this with respect to x . So, this is nothing, but $\frac{\partial S}{\partial x}$ of t_f of this my $\frac{1}{2} x^T F x$ this is my S , F of t_f x of t_f this value I have to find and this is nothing but my F of t_f , x of t_f , this is giving me λ^T of t_f . So, by this we got my λ^T of t_f of F of t_f , x of t_f . So, I am getting my λ^T of t_f of F of t_f and x of t_f . So, this is my terminal condition. So, what I will have here? I have my Hamiltonian system given as $\dot{x} = A x - B R^{-1} B^T \lambda - A x$. So, this is my Hamiltonian system with final condition as $\lambda^T(t_f) = F x(t_f) + \phi$.

So, today we stop here and in the next class we will complete our derivation to obtain the optimal control law for a linear quadratic optimal control system.

Thank you very much.
