Lecture - 03
The Basic Variational Problem

Welcome friends to the session of our discussion. In the previous session we are discussing about the basic concept of the calculus of variation. So, we have defined the function; functional increment in a function, increment in a functional. Important in this is the variation of a functional which we will find, if we will, we can define the increment in J as $J(x(t) + \delta x(t)) - J(x(t))$.

(Refer Slide Time: 00:57)

Calculus of Variations

Variation of a Functional:
Consider the increment of a functional

$$\Delta J = J(x(t) + \delta x(t)) - J(x(t))$$

Expanding $J(x(t) + \delta x(t))$ in a Taylor series

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, this means we are subtracting the value of J at x t point from the value of J which is at the variation of delta x t in the x t we will have.

(Refer Slide Time: 01:18)

Calculus of Variations

Variation of a Functional:

$$\begin{aligned}\Delta J &= J(x(t)) + \frac{\partial J}{\partial x} \delta x(t) + \frac{1}{2!} \frac{\partial^2 J}{\partial x^2} (\delta x(t))^2 + \dots - J(x(t)) \\ &= \frac{\partial J}{\partial x} \delta x(t) + \frac{1}{2!} \frac{\partial^2 J}{\partial x^2} (\delta x(t))^2 + \dots \\ &= \delta J + \delta^2 J\end{aligned}$$

where $\delta J = \frac{\partial J}{\partial x} \delta x(t)$ $\delta^2 J = \frac{1}{2!} \frac{\partial^2 J}{\partial x^2} (\delta x(t))^2$

δJ and $\delta^2 J$ are called the first variation (or simply the variation) and the second variation of the functional J , respectively.

So, to explain this we expand it using the Taylor series and we find that the variation can be expressed as the first variation, second variation and the other higher order terms, where first variation is defined as the linear term which is δJ by δx into δx . The second variation is $\frac{1}{2!}$ factorial to $\delta^2 J$ by δx square δx .

So, this variation will become important once we will find out the optimum values. So, we say, the optimum point δJ should be 0 that will see little bit later on.

(Refer Slide Time: 01:59)

Optimum of a Function

A function $f(t)$ is said to have a relative optimum at the point t^* if there is a positive parameter ϵ such that for all points t in a domain D that satisfy $|t - t^*| < \epsilon$, the increment of $f(t)$ has the same sign (positive or negative).

$\Delta f = f(t) - f(t^*) \geq 0$ then, $f(t^*)$ is a relative local *minimum*.

$\Delta f = f(t) - f(t^*) \leq 0$ then, $f(t^*)$ is a relative local *maximum*.

So, today we will start our discussion with the optimum of a function. Means we are trying to find out the optimal value if a function is given. By definition we can define, a function $f(t)$ is said to have a relative optimum at a given point say t^* if there is a positive parameter ϵ such that for all points t in a domain D that satisfy $|t - t^*| < \epsilon$ the increment of $f(t)$ has the same sign, either positive or negative.

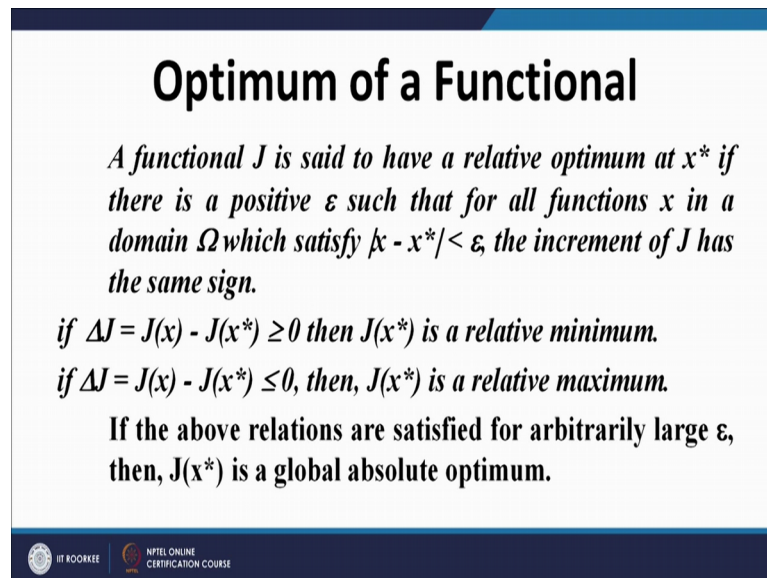

(Refer Slide Time: 02:39)

This means if we will have a function $f(t)$ which can vary in a different ways. So, at a given point we will try to find out what actually will be my optimum point. So, if I will select suppose the lowest point which normally we said to be the optimum. So, in that case what we are saying my t is bounded between $t - \epsilon$ to $t + \epsilon$.

So, if I will take this access as a t , so I can say this is my t^* point. So, a region we are selecting which is less than what is the region we have taken as the ϵ . So, the increment $f(t)$ has the same sign. So, this means if I will get the increment of the $f(t)$ which will be $f(t) - f(t^*)$ that always will be positive if I have a local minima. So, this means all the points beyond this either on this side or in this side will have a value greater than $f(t^*)$. So, if $f(t^*)$ is subtracted from any value here then we said my point is a local minima because local in the sense I have selected this for a very bounded region because if I will go further maybe my another point can appear here, this may be say t_1^* .

(Refer Slide Time: 06:00)

Optimum of a Functional

A functional J is said to have a relative optimum at x^ if there is a positive ε such that for all functions x in a domain Ω which satisfy $|x - x^*| < \varepsilon$, the increment of J has the same sign.*

if $\Delta J = J(x) - J(x^) \geq 0$ then $J(x^*)$ is a relative minimum.*

if $\Delta J = J(x) - J(x^) \leq 0$, then, $J(x^*)$ is a relative maximum.*

If the above relations are satisfied for arbitrarily large ε , then, $J(x^*)$ is a global absolute optimum.

IIT POORKEE | NPTEL ONLINE CERTIFICATION COURSE

Similarly, we can define the optimum of a functional here functional is a function of. So, J is a function of a function x^* . So, what we are saying let J will have the optimum value of the function is a x^* . So, in this case there is a positive epsilon such that all function x in a domain which satisfy x minus x^* less than epsilon the increment J as the same sign. So, this means if x^* is my optimal point then if J will find the increment then $J(x) - J(x^*)$ will be greater than 0 then $J(x^*)$ is nothing, but a relative minimum point. And similarly if ΔJ is less than 0 $J(x) - J(x^*)$ is less than 0 then $J(x^*)$ is a relative maximum.

So, if the above relations are satisfied arbitrarily for large sigma then we say $J(x^*)$ is a global absolute optimum, optimum means if its increment is greater than 0 we say is a minima, increment is less than 0 we say its maximum. And the increment of a functional we have seen that this is given as my first variation, second variation and the higher variation.

So, naturally if my first variation will set to 0 then the sign of ΔJ is governed by the my second variation and at optimum point as my slope will goes 0. So, when the first variation will become 0 that will be my optimum point and the sign will be governed by the second variation.

(Refer Slide Time: 08:05)

Optimum of a Functional

THEOREM

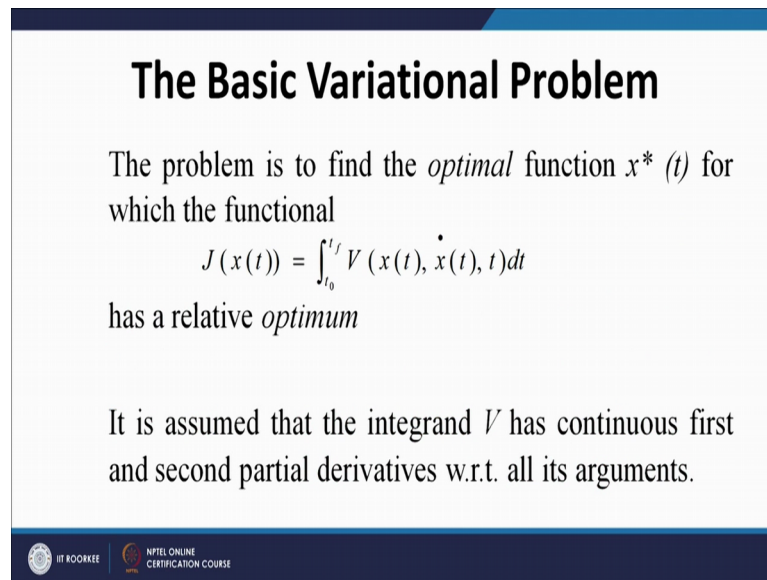

For $x^*(t)$ to be a candidate for an optimum, the **(first variation)** of J must be zero on $x^*(t)$, i.e., $\delta J(x^*(t), \delta x(t)) = 0$ for all admissible values of $\delta x(t)$. This is a **necessary condition**. As a **sufficient condition for minimum**, the second variation $\delta^2 J > 0$, and for **maximum** $\delta^2 J < 0$.

So, on this basis we will have, the fundamental theorem of calculus of variation which state that: For x^* to be a candidate for an optimum, the first variation of J must be zero, this means we are saying J is equal to 0 if x^* is an optimum point. So, this will be my necessary condition and has a sufficient condition for minimum, $\delta^2 J$ must be greater than 0 and $\delta^2 J$ must be less than 0 for maximum that we can see again from my increment point if my first variation is 0 then the sign of $\delta^2 J$ will be governed by the second variation. So, $\delta^2 J$ should be positive for minima, therefore, $\delta^2 J$ should be positive. $\delta^2 J$ should be negative for maxima, so $\delta^2 J$ should be negative. So, that is my fundamental theorem of calculus of variation.

At optimum point my δJ will be 0 which satisfy by necessary condition and $\delta^2 J$ is greater than 0 if I have a minimum point and $\delta^2 J$ is less than 0 if I will have the maximum point.

(Refer Slide Time: 09:21)

The Basic Variational Problem

The problem is to find the *optimal* function $x^*(t)$ for which the functional

$$J(x(t)) = \int_{t_0}^{t_f} V(x(t), \dot{x}(t), t) dt$$

has a relative *optimum*

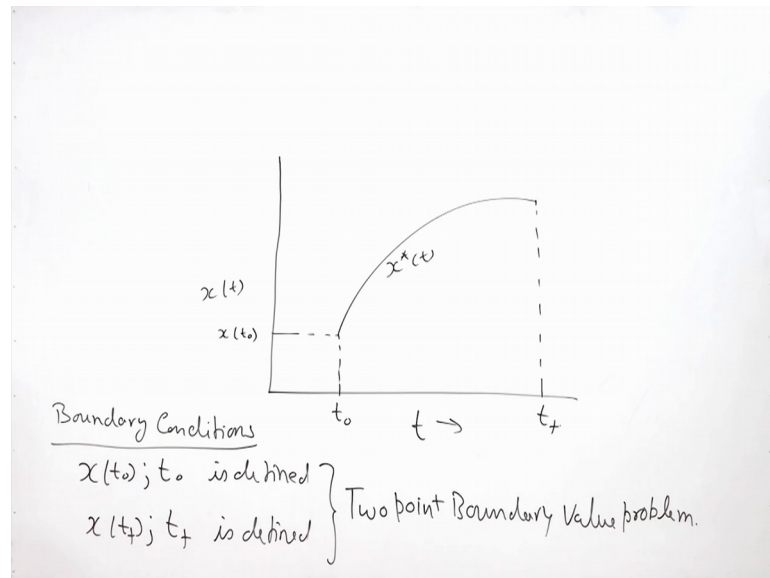

It is assumed that the integrand V has continuous first and second partial derivatives w.r.t. all its arguments.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, based on this we apply our knowledge of function functional increment and variations to determine what is the optimal value of a function x^* which will give me the optimum value for J . So, my objective is the problem is to find the optimal function x^* for which the functional J will have a relative optimum point.

So, what I have to do? Basically I have to find the increment, from increment we will find out the first and the second variation, we set the first variation to 0 for my necessary condition and this will lead to me a differential equation which we have to solve subjected to the boundary condition and then we will check whether my second variation is positive or negative, if it is positive this will be maxima if it is negative then this will be minima.

(Refer Slide Time: 10:44)

So, for the given J we assume let my x^* , I already have say x^* . So, let this represent my optimal trajectory x^* of t . t_0 is my starting point, at t_0 let I will have the value as $x(t_0)$, this is my t_f point. Now once we are solving this optimal problem we must be defined with the boundary condition what may be the boundary condition means? What is the value of my function $x(t)$ at t_0 and t_f , normally from control point of if we will see $x(t_0)$ and t_0 is defined, defined means this values are given from where we are starting and what is the my initial conditions.

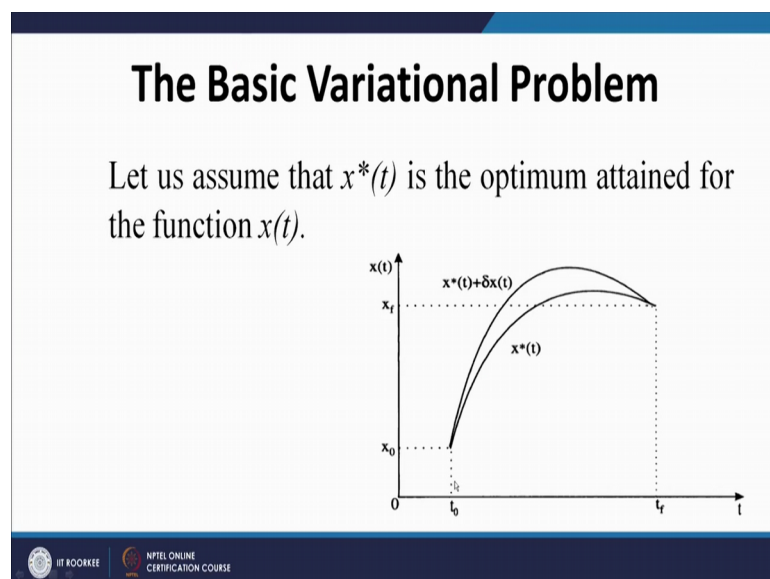

But final condition depends upon the nature of the problem. The first problem we are taking in which $x(t_f)$ and t_f is defined; this means we also know what is my t_f and what is my x of t_f . So, this is known as the two point boundary value problem. So, we are given with the initial point, we are given with the final point - t_0 t_f both are given, $x(t_0)$ and $x(t_f)$ are also given, so my optimal trajectory starting from the t_0 and terminating at the t_f .

(Refer Slide Time: 13:56)

So, at final points I know where is my trajectory. Let us consider a variation of $\delta x(t)$. So, I can say this is my $x(t)$ which is not at the optimal point. So, we are considering let there exist a optimal trajectory $x^*(t)$ starting from the t_0 and terminating to the t_f point we are considering a variation of $\delta x(t)$ in $x^*(t)$, my terminal points are bounded. So, my variation is also starting from the t_0 point and terminating to the t_f point.

(Refer Slide Time: 14:56)

So, this is my condition I am given with the t_0 and $x(t_0)$ and $x(t_f)$ which is the value at the t_f point this is my optimal trajectory and this is the variation in the optimal trajectory. So, for a given value of the x , I can write J at the x^* point and J at the x point.

(Refer Slide Time: 15:24)

$$\begin{aligned}
 \Delta J &= J(x^*(t_0) + \delta x(t_0)) - J(x^*(t_0)) \\
 \Delta J &= \int_{t_0}^{t_f} [V(x^* + \delta x, \dot{x}^* + \delta \dot{x}, t) - V(x^*, \dot{x}^*, t)] dt \\
 &\quad \downarrow \text{Expanding using Taylor Series} \\
 &= \int_{t_0}^{t_f} \left[V(x^*, \dot{x}^*, t) + \left(\frac{\partial V(\cdot)}{\partial x} \right)_x \delta x(t) + \left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right)_x \delta \dot{x}(t) + h.o.t \dots - V(x^*, \dot{x}^*, t) \right] dt \\
 &= \int_{t_0}^{t_f} \left[\left(\frac{\partial V(\cdot)}{\partial x} \right)_x \delta x(t) + \left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right)_x \delta \dot{x}(t) + h.o.t \right] dt
 \end{aligned}$$

So, as my to start my problem my objective is to find out the increment in the J and by definition increment on the J is defined as J at $J x^*$ plus delta x t point minus J at x^* of t point. This will give me the increment in J , so $J x^* t$ plus delta x t and as we have considered V to be a function of x dot and t .

(Refer Slide Time: 16:00)

The Basic Variational Problem

The increment in J

$$\begin{aligned} \Delta J(x'(t), \delta x(t)) &= J(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) - J(x'(t), \dot{x}'(t), t) \\ &= \int_{t_0}^{t_f} V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) dt - \int_{t_0}^{t_f} V(x'(t), \dot{x}'(t), t) dt \\ &= \int_{t_0}^{t_f} [V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) - V(x'(t), \dot{x}'(t), t)] dt \end{aligned}$$

If I am giving a variation in x at t , so there is a variation in the \dot{x} at t also. So, that is why we are saying x at t plus δx at t and \dot{x} at t plus $\delta \dot{x}$ at t minus J of x star at t and \dot{x} star at t . So, that is we have considered a general form of the functional which is the function of x star at t as well as the function of the \dot{x} star at t . And we know J is V of x star at t and \dot{x} star at t . So, this is $\int_{t_0}^{t_f} V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) dt - \int_{t_0}^{t_f} V(x'(t), \dot{x}'(t), t) dt$. So, these 2 integrals we can combine together because their limits are similar from t_0 to t_f and we can write $\int_{t_0}^{t_f} [V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) - V(x'(t), \dot{x}'(t), t)] dt$. So, my objective is to find out what actually will be my increment.

So, now, this first term I can explain using the Taylor Series. So, we can write ΔJ as $\int_{t_0}^{t_f} V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) dt - \int_{t_0}^{t_f} V(x'(t), \dot{x}'(t), t) dt$. So, I am dropping out the t by writing here because t is repeated. So, I am simply writing as $V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) - V(x'(t), \dot{x}'(t), t)$. This will be x star plus δx , \dot{x} star plus $\delta \dot{x}$ and t minus V of x star and \dot{x} star and t . We are expanding the first term only. So, only the first term we are expanding using Taylor Series. So, what actually we will get - $\int_{t_0}^{t_f} V(x'(t) + \delta x(t), \dot{x}'(t) + \delta \dot{x}(t), t) dt - \int_{t_0}^{t_f} V(x'(t), \dot{x}'(t), t) dt$. So, my first term will be $V(x'(t), \dot{x}'(t), t)$, my second is the first variation $\frac{\partial V}{\partial x} \delta x + \frac{\partial V}{\partial \dot{x}} \delta \dot{x}$ at my optimal point into δx and $\delta \dot{x}$ plus higher order terms and my last term is minus $V(x'(t), \dot{x}'(t), t)$ into dt . So, in this I can cancel out this term. So, I am left with $\int_{t_0}^{t_f} \frac{\partial V}{\partial x} \delta x + \frac{\partial V}{\partial \dot{x}} \delta \dot{x} + \text{higher order terms} dt - \int_{t_0}^{t_f} V(x'(t), \dot{x}'(t), t) dt$. So, V already have been cancelled out. So, we are simply

defining the del V by del x, del V by del x dot delta x dot 1 by factorial to my higher order term which is my the second order term plus the another higher order terms.

(Refer Slide Time: 21:06)

The Basic Variational Problem

$$\Delta J = \int_{t_0}^{t_f} \left[\frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial x} \delta x(t) + \frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial \dot{x}} \delta \dot{x}(t) + \frac{1}{2!} \left[\frac{\partial^2 V(\dots)}{\partial x^2} (\delta x(t))^2 + \frac{\partial^2 V(\dots)}{\partial x^2 \partial \dot{x}} (\delta x(t) \delta \dot{x}(t)) + 2 \frac{\partial^2 V(\dots)}{\partial x \partial \dot{x}} \delta x(t) \delta \dot{x}(t) \right] + \dots \right] dt$$

\dot{x}

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, del J I can write in this form. The first 2 term are basically representing my first variation and this is representing my second variation.

(Refer Slide Time: 21:33)

The Basic Variational Problem

The first variation

$$\delta J(x^*(t), \delta x(t)) = \int_{t_0}^{t_f} \left[\frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial x} \delta x(t) + \frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial \dot{x}} \delta \dot{x}(t) \right] dt$$

Considering

$$\int_{t_0}^{t_f} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \delta \dot{x}(t) dt = \int_{t_0}^{t_f} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \frac{d}{dt} (\delta x(t)) dt = \int_{t_0}^{t_f} \left(\frac{\partial V}{\partial \dot{x}} \right)_* d(\delta x(t))$$

$$= \left[\left(\frac{\partial V}{\partial \dot{x}} \right)_* \delta x(t) \right]_{t_0}^{t_f} - \int_{t_0}^{t_f} \delta x(t) \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right)_* dt$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, I can write my first variation is delta J equal to del V by del x delta x plus del V by del x dot delta x dot. So, the first variation will have the 2 terms - one in delta x t form, other is as the coefficient of delta x dot of t. So, in the next we will try to convert the

second term which is in the delta x dot of t form in delta x t form and this we can do using the property of the integration and integrating it by parts.

(Refer Slide Time: 22:25)

Consider the IInd term of first Variation

$$\int_{t_0}^{t_1} \left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right)_* \delta \dot{x} dt$$

$$= \int_{t_0}^{t_1} \left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right)_* \frac{d(\delta x)}{dt} dt$$

$$= \int_{t_0}^{t_1} \underbrace{\left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right)_*}_u d \underbrace{(\delta x)}_v$$

$$= - \int_{t_0}^{t_1} \delta x(t) \frac{d}{dt} \left(\frac{\partial V(\cdot)}{\partial \dot{x}} \right) dt + \left[\frac{\partial V(\cdot)}{\partial \dot{x}} \cdot \delta x(t) \right]_{t_0}^{t_1}$$

$$\left\{ \begin{aligned} \int_{t_0}^{t_1} d(uv) &= \int_{t_0}^{t_1} v du + \int_{t_0}^{t_1} u dv \\ \int_{t_0}^{t_1} u dv &= - \int_{t_0}^{t_1} v du \\ &+ [uv]_{t_0}^{t_1} \end{aligned} \right.$$

So, we are considering consider the second term of first variation and what is my second term? That is integral t 0 to t f del v, I am simply writing del V dot by del x dot at optimal point into delta x dot d t. So, we are considering only this term del V by del x dot delta x dot and this we are integrating by parts. So, we are you using say if I will write the d u v. So, this is nothing but v d u plus u d v. If I will integrate this with the given limit let us say t 0 to t f, t 0 to t f, t 0 to t f and write this term. So, I can write integral t 0 to t f u d v as minus integral t 0 to t f, v d u plus. So, if I will integrate this, what actually I am getting? I am getting simply u v, t 0 to t f means u and v we evaluated at t 0 and t f point. So, this if I will write as t 0 to t f v dot by del x dot and this I will write d by d t into delta x.

So, delta x what I am writing d by d t o delta x. So, this is giving me the delta x dot and this is multiplied with the d t. So, naturally if d t d t will be cancelled out. So, this is t 0 to t f del V by del x dot and this I will right the delta x. So, what I say? Let us say this is my u d of v and delta x is my v. So, what I can write from here? So, this is my u d v, u of d v is minus integral of v, v is nothing but my delta x, d u means d of del V dot by delta x dot. So, this is the v d u plus u d v and u is my del V dot by del x dot into delta x of t

because this δx is a function of time. This means this is also my $\delta x(t)$ because I have drop out the t , I am taking this t inside varying from t_0 to t_f . So, this is my case.

So, if I will write this is d by $d t$ and I multiply $d t$ here. So, this term I can simply represent as $\frac{\partial V}{\partial x} \delta x$ from t_0 to t_f which is my last term here and minus integral t_0 to t_f $\delta x \frac{d}{dt} \frac{\partial V}{\partial \dot{x}}$ into $d t$. So, this second term I can expand by these 2 terms. And if I will substitute this second term in this form what actually I will get. So, you can see here this is $\frac{\partial V}{\partial x} \delta x$, this is d by $d t$ $\frac{\partial V}{\partial \dot{x}}$ by δx .

(Refer Slide Time: 28:38)

The Basic Variational Problem

The first variation

$$\begin{aligned} \delta J(x^*(t), \delta x(t)) &= \int_{t_0}^{t_f} \left(\frac{\partial V}{\partial x} \right)_* \delta x(t) dt + \left[\left(\frac{\partial V}{\partial \dot{x}} \right)_* \delta x(t) \right]_{t_0}^{t_f} - \int_{t_0}^{t_f} \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \delta x(t) dt \\ &= \int_{t_0}^{t_f} \left[\left(\frac{\partial V}{\partial x} \right)_* - \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \right] \delta x(t) dt + \left[\left(\frac{\partial V}{\partial \dot{x}} \right)_* \delta x(t) \right]_{t_0}^{t_f} \end{aligned}$$

Using boundary conditions

$$\delta J(x^*(t), \delta x(t)) = \int_{t_0}^{t_f} \left[\left(\frac{\partial V}{\partial x} \right)_* - \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \right] \delta x(t) dt$$

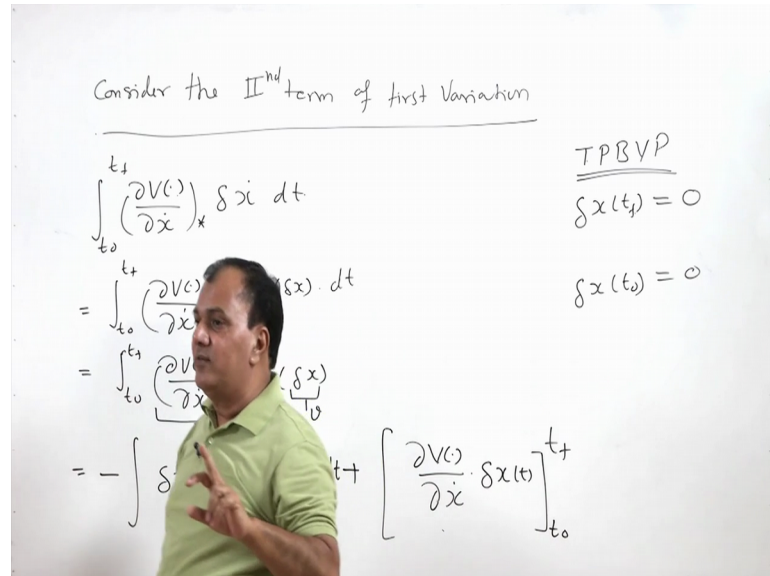

So, I can simply write this as $\frac{\partial V}{\partial x} \delta x$ this is my first term, this is boundary point minus d by. So, this whole represent my second term.

So, this 2 integral I will club together to write as $\frac{\partial V}{\partial x} \delta x$ minus d by $d t$ $\frac{\partial V}{\partial \dot{x}}$ by δx multiplied with δx . Now this δx is a common factor plus $\frac{\partial V}{\partial x} \delta x$. Now see what the boundary conditions we have considered. So, in this, if we will see; so the 2 term here one is integral term, other is the term with the limits t_0 to t_f . So, what is, if I will place the value of t_0 and t_f here? So, this is this variation is at the t_0 point and $\delta x(t_f)$ is the variation at the t_f point. So, that is why this boundary condition. So, I can say the last term in this expression is giving me the boundary conditions while the first term giving me a differential equation in d by $d t$ form.

So, this is a non-linear equation which I am getting and another term and getting as a boundary condition.

(Refer Slide Time: 30:14)

In our, this two point boundary value problem my initial and the final point is. So, two point boundary value problem TPBVP, two point boundary value problem if you are considering. So, this means I have the one term delta x of t f and another term is delta x of t 0 and as we have considered the case at t 0 my this value is fixed so there is no delta x of t 0 this will be 0 and a t f again my this point is fixed. So, this will be delta x of t f. So, this means I can set this value to 0, this value to 0, but only in the case of the two point boundary value problem. Later we will see the free end point problem in which we will make, we will keep the initial point fixed, but we will make the final time as well as the final state to be free.

So, in this case if we will consider the two point boundary value problem. So, my first variation is simply equal to t 0 to t f del V by del x minus d by d t del V by del x dot delta x t d t and what is my fundamental theorem to get the optimum value? My first variation must be equal to 0 at the optimum point.

(Refer Slide Time: 31:52)

The Basic Variational Problem

For the optimum $x^*(t)$ to exist,

$$\delta J(x^*(t), \delta x(t)) = 0$$
$$\int_{t_0}^{t_f} \left[\left(\frac{\partial V}{\partial x} \right)_* - \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right)_* \right] \delta x(t) dt = 0$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, for optimum x is start t_2 adjust my δJ must be equal to 0, this means my t_0 to t_f δV by δx minus $\frac{d}{dt} \delta V$ by $\delta \dot{x}$ must be equal to 0. But this term is with the integral, now if you will see this whole rule of the 2 major parts one is in this bracket δV by δx minus $\frac{d}{dt} \delta V$ by $\delta \dot{x}$ and the δx .

(Refer Slide Time: 32:22)

The Basic Variational Problem

LEMMA

If for every function $g(t)$ which is continuous,

$$\int_{t_0}^{t_f} g(t) \delta x(t) dt = 0$$

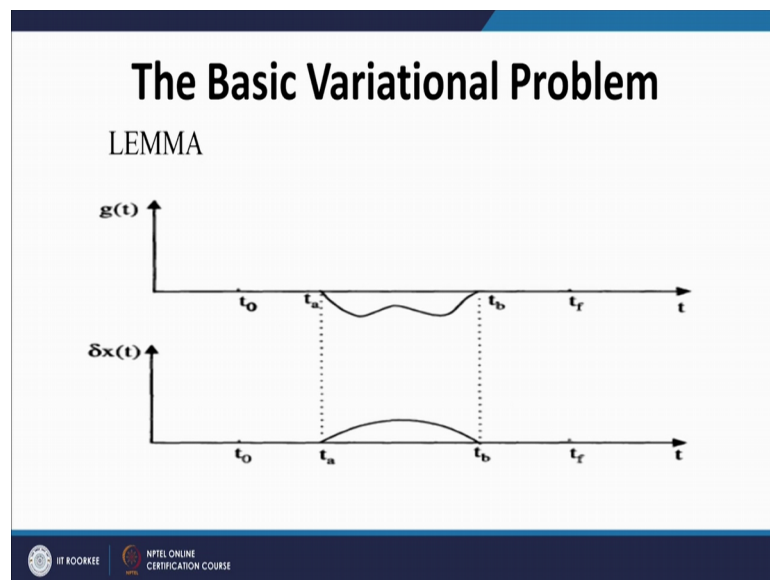

where the function $\delta x(t)$ is continuous in the interval $[t_0, t_f]$, then the function $g(t)$ must be zero everywhere throughout the interval $[t_0, t_f]$.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, we use the fundamental lemma which is given as $\int_{t_0}^{t_f} g(t) \delta x(t) dt = 0$. Now in this case my $\delta x(t)$ is the variation which is arbitrary which normally cannot be 0. So, if $\delta x(t)$ cannot be 0 this means my $g(t)$ value should be 0, this is called my

fundamental lemma for every function $g(t)$ which is continuous given as t_0 to t_f , $\int_{t_0}^{t_f} g(t) \delta x(t) dt = 0$ where the function $\delta x(t)$ is continuous in integral then the $g(t)$ must be 0 everywhere throughout the integral. So, throughout the interval t_0 to t_f if $\delta x(t)$ is continuous.

(Refer Slide Time: 33:15)

This we can prove your let in some interval $\delta g(t)$ is not 0 if $\delta g(t)$ is not 0, $x(t)$ is changing $d(t)$ is changing. So, during this interval what is my assumption? The product of $g(t)$ and $\delta x(t) dt$ must be 0 that is not true. So, this is contradicting my assumption let $g(t) \delta x(t) dt = 0$. So, this means if $\delta x(t)$ is arbitrary my $g(t)$ will be 0 and in this case I can say this is my $\delta x(t)$ and if my $g(t)$ is this. So, for this integral to be 0 $\delta x(t)$ is arbitrary and continuous; my $d(t)$ will be 0 this means my δV by dx minus d by dt δV by δx dot will be equal to 0.

(Refer Slide Time: 34:04)

The Basic Variational Problem

Using lemma to fundamental theorem, a necessary condition for $x^*(t)$ to be an optimal of the functional J

$$\left(\frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial x}\right)_* - \frac{d}{dt} \left(\frac{\partial V(x^*(t), \dot{x}^*(t), t)}{\partial \dot{x}}\right)_* = 0$$
$$\left(\frac{\partial V}{\partial x}\right)_* - \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}}\right)_* = 0$$

for all $t \in [t_0, t_f]$.

This equation is called the Euler equation

In simple form we can directly write $\frac{\partial V}{\partial x}$ at optimal point minus $\frac{d}{dt} \frac{\partial V}{\partial \dot{x}}$ at optimal point that must be equal to 0 for the complete interval from t_0 to t_f and this is called my Euler equation.

So, I stop my discussion for this session at this point and more detail of this basic variational problem we will discuss in the next class. And we will also take up an example to see the application of this basic variational problem.

Thank you very much.
