Lecture - 37
The Hamilton-Jacobi-Bellman (HJB) Equation

Welcome friends to the session of our discussion. In today session we will discuss about the application of the dynamic programming on continuous time system; in the previous class we have seen that how the dynamic programming approach can be applied to a discrete system.

This dynamic approach is basically based on our principle of optimality which we have discussed in the previous class we say the optimal policy as the property that whatever the previously stated decisions the remaining decisions was must constitute an optimal policy with regard to the state resulting from the previous decisions.

(Refer Slide Time: 01:04)

The Hamilton-Jacobi-Bellman (HJB) Equation

Consider the plant as

$$\dot{\mathbf{x}}(t) = \mathbf{f}(\mathbf{x}(t), \mathbf{u}(t), t)$$
$$\mathbf{x}(t) = \mathbf{x}_0$$

and the cost function

$$J(\mathbf{x}(t), \mathbf{u}(t), t) = S(\mathbf{x}(t_f), t_f) + \int_t^{t_f} V(\mathbf{x}(\tau), \mathbf{u}(\tau), \tau) d\tau$$

Objective is to find the optimal control $\mathbf{u}^*(\tau)$ using the principle of optimality which applied to the plant gives optimal state $\mathbf{x}^*(k)$.

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

Let us consider a continuous plant given as $\dot{x} = f(x, u, t)$ general plant we are considering maybe linear or non-linear with initial condition $x(t) = x_0$ t is my variable parameter which varies from t to t_f . So, this means the initial point we are considering as t and t can take any value.

(Refer Slide Time: 01:50)

$$\begin{aligned}
 & \text{Minimum Cost} \quad J(x(t), t) = S(x(t), t) + \int_t^{t_f} V(x(\tau), u(\tau), \tau) d\tau \quad \left| \begin{array}{l} J(x(t_f), t_f) = S(x(t_f), t_f) \\ J(x(t), t) = S(x(t), t) \end{array} \right. \\
 & J^*(x(t), t) = \min_{u(\tau)} \left\{ \int_t^{t_f} V(x(\tau), u(\tau), \tau) d\tau + S(x(t_f), t_f) \right\} \\
 & = \min_{u(\tau)} \left\{ \int_t^{t+\Delta t} V(\cdot) d\tau + \underbrace{\int_{t+\Delta t}^{t_f} V(\cdot) d\tau + S(x(t_f), t_f)}_{\substack{\text{Cost to transfer state } x(t+\Delta t) \text{ to } x(t_f) \\ J^*(x(t+\Delta t), t+\Delta t)}} \right\} \\
 & \text{By principle of optimality} \\
 & J^*(x(t), t) = \min_{u(\tau)} \left\{ \int_t^{t+\Delta t} V(x(\tau), u(\tau), \tau) d\tau + J^*(x(t+\Delta t), t+\Delta t) \right\} \\
 & J^*(x(t+\Delta t), t+\Delta t) \text{ is the minimum cost to transfer } x(t+\Delta t) \text{ to } x(t_f) \\
 & x(t+\Delta t) = x(t) + \int_{t+\Delta t}^t \dot{x}(x, u, \tau) d\tau = x(t) + \Delta x(t)
 \end{aligned}$$

Now, we define a Cost function as $J(x, t)$ as a function of x and t which defines the terminal cost plus the integral value as $\int_t^{t_f} V(x, u, \tau) d\tau$ here τ lies between t to t_f . So, here what the $J(x, t)$ represents this represents the cost of transferring the state x at t to x at t_f in a time interval of t to t_f .

So, this $J(x, t)$ representing my cost to transfer the state at its initial value, let us say x at t to x at t_f value now the objective here is again to find out the optimal value of the u^* using the principle of optimality which applied to the plant and gives the optimal states. So, as we have defined my J which we are saying as x at t my terminal cost S of t_f plus integral $\int_t^{t_f} V$, we are seeing the τ here using the variable u and θ . So, this is my Cost function and $J(x, t)$ to represent the cost to transfer the state from x at t to x at t_f .

So, if I will write the boundary point as $J(x, t_f)$ which is nothing but my S of t_f . So, this is my terminal point at terminal point this is the only cost which is involved. So, I can see this will be my optimal cost at the terminal state x at t_f because x at t_f is my final state beyond this I am not transferring. So, at this stage terminal point whatever be the cost that I can say will be my optimal cost now this $J(x, t)$, I can write by breaking the integral or see let us say what is my minimum cost minimum cost means what is the optimal value of the $J(x, t)$ this I can write as I have to minimize u where τ is

varying between t to t_f with let us say I write in this form t to t_f $V \times \tau u \tau d \tau$ plus s of x of t_f t_f .

This means I have to minimize this objective function with respect to $u \tau$ because my objective is to find out the optimal value of the u . So, that I will get this function get minimized and I will get the minimized cost as J^* . So, this I can write as $u \tau t$ plus sorry t_f and this integral I break from t to t plus Δt $V d \tau$ plus t plus Δt to t_f τ plus my s this is x of t_f t_f point.

Now, what this represent here second τ this second term is the cost to transfer the state from $x t$ plus Δt this is the cost to transfer state $x t$ plus Δt to x of t_f . So, this is my cost to transfer the state from this point $x t$ plus Δt to x of t_f and if I will say this is nothing but my $J x t$ plus Δt $u t$ plus Δt and t plus Δt . So, this means if I will apply the principle of optimality by the principle of optimality if my; this cost is minimum I can assume my this cost to be the minimum. So, I can simply write as my $J^* x t$ as minimum $u \tau$ and I am minimizing the $u \tau$ only for t to t plus Δt and let beyond t plus Δt to t_f I already have my minimum cost. So, I can write this as t to t plus Δt V I am writing the full $x \tau u \tau \tau d \tau$ plus this I can write as $J^* x t$ plus Δt t plus sorry t plus Δt .

So, at this stage this is I already have minimized with respect to u . So, this J^* is independent for my u , but this x will be as x plus 1, we have considered as the $f x u t$. So, this is my f . So, this means we still my whole expression will depend on $u \tau$ between the time interval t to t plus Δt . So, this is my minimum cost. So, we can say $J^* x t$ plus Δt t plus Δt is the minimum cost to transfer x from t plus Δt to x of t_f . So, this will be my minimum cost and what is my $x t$ plus Δt this is nothing but my $x t$ the initial cost which is given as the x_0 we have considered plus whatever be the state resulting from t plus Δt to t_f point if I will solve my $f x u t d t$ and this I can simply write as $x t$ plus Δx of t . So, means my initial state to determine this is varying which we can find out by this. So, this is the meaning of my $J^* s t$ plus Δt $d t$.

Now, we can expand now expand $J^* x t$ plus Δt t plus Δt because the variation at the point t using Taylor series. So, we can expand this using the Taylor series what actually we will get by this $J x t$ plus Δt t plus Δt if I will expand.

(Refer Slide Time: 13:07)

$$\begin{aligned}
 & J(x(t_1), t_1) = S(x(t_1), t_1) + \int_t^{t_1} V(x(\tau), u(\tau), \tau) d\tau \quad \left| \quad \underline{J^*(x(t_1), t_1)} = S(x(t_1), t_1) \right. \\
 \text{Minimum Cost} & \\
 J^*(x(t_1), t_1) &= \min_{u(\cdot)} \left\{ \int_t^{t_1} V(x(\tau), u(\tau), \tau) d\tau + S(x(t_1), t_1) \right\} \\
 &= \min_{u(\cdot)} \left\{ \int_t^{t+\Delta t} V(\cdot) d\tau + \underbrace{\int_{t+\Delta t}^{t_1} V(\cdot) d\tau + S(x(t_1), t_1)}_{\substack{\text{Cost to transfer state } x(t+\Delta t) \text{ to } x(t_1) \\ J^*(x(t+\Delta t), u(t+\Delta t), t+\Delta t)}} \right\} \\
 \text{By principle of optimality} & \\
 J^*(x(t), t) &= \min_{u(\cdot)} \left\{ \int_t^{t+\Delta t} V(x(\tau), u(\tau), \tau) d\tau + J^*(x(t+\Delta t), t+\Delta t) \right\} \\
 \text{Expand } J^*(x(t+\Delta t), t+\Delta t) & \text{ using Taylor Series} \\
 J^*(x(t+\Delta t), t+\Delta t) &= J^*(x(t), t) + \frac{\partial J^*(x(t), t)}{\partial t} \Delta t + \frac{\partial J^*(x(t), t)}{\partial x(t)} \Delta x(t) + \text{h.o.t.} \\
 & \quad \uparrow \text{Independent of } u \quad \leftarrow \text{Independent of } u \quad \rightarrow \text{Neglect}
 \end{aligned}$$

So, what I am getting J^* of x t plus $\frac{\partial J^*}{\partial t} \Delta t$ because now my I have the variation in the t which is varying from t to $t + \Delta t$. So, I have the term $\frac{\partial J^*}{\partial t} \Delta t$ plus. Now second is x t by Δx of t Δx t plus my higher order terms and higher order terms will also be the function of your Δt and Δx , but if you will consider the variation in Δt to be very small. So, from this we can neglect this higher order term these terms we neglect.

So, in this expression this J^* x t plus Δt plus Δt we can replace by this whole term and this whole term if you will see this is my minimum which is not dependent on my u . So, this term will be independent of u similarly $\frac{\partial J^*}{\partial x(t)}$ also independent; independent from independent of u .

(Refer Slide Time: 15:36)

$$J^*(x(t), t) = J^*(x(t), t) + \frac{\partial J^*(t)}{\partial t} \Delta t + \text{Min}_{u(\tau) \in S, t \leq \tau \leq t+\Delta t} \left\{ \int_t^{t+\Delta t} V(x(\tau), u(\tau), \tau) d\tau + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \Delta x \right\}$$

dividing both side by Δt

$$0 = \frac{\partial J^*(t)}{\partial t} + \text{Min}_{u(\tau) \in S, t \leq \tau \leq t+\Delta t} \left\{ \frac{1}{\Delta t} \int_t^{t+\Delta t} V(\cdot) d\tau + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \frac{\Delta x}{\Delta t} \right\}$$

As $\Delta t \rightarrow 0$

$$\lim_{\Delta t \rightarrow 0} \frac{1}{\Delta t} \int_t^{t+\Delta t} V(\cdot) d\tau = V(x(t), u(t), t)$$

$$\lim_{\Delta t \rightarrow 0} \left[\frac{\partial J^*(x(t), t)}{\partial x(t)} \right]^T \frac{\Delta x}{\Delta t} = \left[\frac{\partial J^*(t)}{\partial x} \right]^T \dot{x} = \left[\frac{\partial J^*(t)}{\partial x} \right]^T f(x(t), u(t), t)$$

$$0 = \frac{\partial J^*(t)}{\partial t} + \text{Min}_{u(t)} \left\{ V(x(t), u(t), t) + \left[\frac{\partial J^*(t)}{\partial x} \right]^T f(x(t), u(t), t) \right\}$$

or $J^*(x(t+\Delta t), t+\Delta t)$ using Taylor Series

$$J^*(x(t+\Delta t), t+\Delta t) = J^*(x(t), t) + \frac{\partial J^*(x(t), t)}{\partial t} \Delta t + \left[\frac{\partial J^*(x(t), t)}{\partial x(t)} \right]^T \Delta x(t) + h.o.t$$

Independent Δt Independent Δx Neglect

So, these 2 terms we get. So, for $J^* x t$ what we are writing say in this expression if I will replace them this is independent of u this is independent of u . So, these 2 terms I can take it outside from the minimization. So, if I will write here. So, these 2 terms I can write outside from my minimization I am writing. So, this is $J^* x t$ plus $\frac{\partial J^*}{\partial t}$ having the same meaning by $\frac{\partial J^*}{\partial t} \Delta t$ plus minimization of u where τ is within the interval of t to $t + \Delta t$ I have V sorry integral from t to $t + \Delta t$ $V x \tau u \tau d \tau$ plus my second term $\frac{\partial J^*}{\partial x}$ say if we will make this. So, this is nothing but because we have to multiply x is my vector and this will be also be $\frac{\partial J^*}{\partial x} \Delta x$ by $\frac{\partial J^*}{\partial x} \Delta x$. So, I have to take to transpose to this. So, actually this term will be $\frac{\partial J^*}{\partial x}$ by $\frac{\partial J^*}{\partial x}$ whole transpose multiplied with $\frac{\partial x}{\partial t}$. So, this is transpose Δx and the higher terms we already have been neglected.

So, in this equation these 2 we cancelled out so this will be 0. And now dividing both sides by Δt . So, what actually we will get this side will be $0 = \frac{\partial J^*}{\partial t} + \text{Min}_{u(\tau) \in S, t \leq \tau \leq t+\Delta t} \left\{ \frac{1}{\Delta t} \int_t^{t+\Delta t} V(\cdot) d\tau + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \frac{\Delta x}{\Delta t} \right\}$. So, this will be 1 plus minimum u where τ is within my range t to $t + \Delta t$. So, I will say this is 1 by Δt integral t to $t + \Delta t$ I am writing this simply as $V \cdot d\tau$ plus this I am writing as $\frac{\partial J^*}{\partial x} \dot{x}$ which will be $\frac{\partial J^*}{\partial x} \dot{x} \Delta t$ as we are saying we are considering Δt to be very small. So, if we will limit Δt approaching to 0.

So, my terms will be limit delta t approaching to 0 my first term is 1 upon delta t to t plus delta t V dot d tau with this limit. So, this is nothing but my V x t. So, this is my V x t u t t we can write for 1 by delta t integral V dot t and limit delta t tends to 0 del J star this is my x t t by delta x t the actual is this. So, this we are basically dropped out in this transpose del x by sorry del t which can be written as with this limit to this. So, this is nothing but your del J star by del x transpose and this is nothing but my x dot which is d x by d t or simply I can write this as del J star by del x transpose and x dot is nothing but my f x t u t t. So, my; this term is replaced by this and this term can be replaced by the second term.

So, I can write this equation as 0 del J star by del t plus minimum. So, now, this whole term is I can take this simply as my u t. So, my first term is replaced by V x t u t t and my second term is del J star by del x transpose f x t u t t. So, I can write.

(Refer Slide Time: 23:18)

The image shows a handwritten derivation on a whiteboard. It starts with the discrete-time cost function:
$$J^*(x(t), t) = J^*(x(t+dt), t) + \frac{\partial J^*(t)}{\partial t} \Delta t + \min_{u(t)} \left\{ \int_t^{t+dt} V(x(u), u(u), t) dt + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \Delta x \right\}$$
Then, it says "dividing both sides by dt" and shows:
$$0 = \frac{\partial J^*(t)}{\partial t} + \min_{u(t)} \left\{ \frac{1}{\Delta t} \int_t^{t+dt} V(\cdot) dt + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \frac{\Delta x}{\Delta t} \right\}$$
As $\Delta t \rightarrow 0$, it simplifies to:
$$0 = \frac{\partial J^*(t)}{\partial t} + \min_{u(t)} \left\{ V(x(t), u(t), t) + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \dot{x} \right\}$$
The term in the braces is identified as the Hamiltonian:
$$0 = \frac{\partial J^*(t)}{\partial t} + \min_{u(t)} \left\{ \underbrace{V(x(t), u(t), t) + \left[\frac{\partial J^*(t)}{\partial x} \right]^T \dot{x}}_{\text{Hamiltonian}} \right\}$$
Finally, it is written as:
$$0 = \frac{\partial J^*(t)}{\partial t} + \min_{u(t)} \left\{ H(x(t), u(t), \frac{\partial J^*(t)}{\partial x}, t) \right\}$$

So, now I will define this whole as my this is equal to I will define this as my Hamiltonian which will be the function of my x t u t this del J star sorry this is del x and naturally t. So, this Hamiltonian is the function of x u del J by del x and t. So, I can write this equation simply as del J by del t plus minimum of u t which is nothing but my h function of x t u t del J by del x and t.

So, this means in the minimization of this I have to minimize the h with respect to u. So, what we have done.

(Refer Slide Time: 25:02)

$$H(x(t), u(t), \frac{\partial J^*}{\partial x}, t) = V(x(t), u(t), t) + \left[\frac{\partial J^*}{\partial x} \right]^T f(x(t), u(t), t)$$

Optimal Value of Control $\frac{\partial H(\cdot)}{\partial u} = 0$

$$u^* = u^*(x(t), \frac{\partial J^*}{\partial x}, t)$$

$$\min_{u(t)} \{ H(x(t), u(t), \frac{\partial J^*}{\partial x}, t) \} = H^*(x(t), \frac{\partial J^*}{\partial x}, t)$$

$$0 = \frac{\partial J^*}{\partial t} + H^*(x(t), \frac{\partial J^*}{\partial x}, t)$$

Hamilton-Jacobi-Bellman's Equation (HJB Eqn)

$$0 = \frac{\partial J^*}{\partial t} + \min_{u(t)} \{ H(x(t), u(t), \frac{\partial J^*}{\partial x}, t) \}$$

We have defined the Hamiltonian which is a function of x , u , $\frac{\partial J^*}{\partial x}$ by $\frac{\partial J^*}{\partial x}$ as my x , u , t , $\frac{\partial J^*}{\partial x}$ plus $\frac{\partial J^*}{\partial t}$ multiplied with $f(x, u, t)$ and to satisfy this equation I have to get the minimum value of the h . So, for optimal control for optimal value of control we have $\frac{\partial h}{\partial u}$ equal to 0 if we will apply this. So, we will this give me the optimal control u^* and we have this u^* will be the function of x, t because we are determining the u in terms of the $x, \frac{\partial J^*}{\partial x}$ and t . So, naturally this; my optimal u is independent of the u term because u, V still determining in terms of the $x, \frac{\partial J^*}{\partial x}$ and t form.

So, I can write this minimum of if I will write u, t as $h(x, t, \frac{\partial J^*}{\partial x}, t)$ and I am substituting u into this. So, I will get nothing but my h^* which will be the function of $x, t, \frac{\partial J^*}{\partial x}, t$. So, I can simply write this equation as $\frac{\partial J^*}{\partial t}$ plus the minimum value of the h which is the function of my $x, t, \frac{\partial J^*}{\partial x}, t$ and this equation is called my Hamilton Jacobi Bellman's equation and more precisely we say HJB equation.

(Refer Slide Time: 29:05)

The Hamilton-Jacobi-Bellman (HJB) Equation

HJB Equation $\frac{\partial J^*(\mathbf{x}^*(t), t)}{\partial t} + \mathcal{H}(\mathbf{x}^*(t), \frac{\partial J^*(\mathbf{x}^*(t), t)}{\partial \mathbf{x}^*}, \mathbf{u}^*(t), t) = 0$

Boundary condition $J^*(\mathbf{x}^*(t_f), t_f) = S(\mathbf{x}^*(t_f), t_f)$

Alternatively $J_t^* + \mathcal{H}(\mathbf{x}^*(t), J_x^*, \mathbf{u}^*(t), t) = 0$

$J_t^* = \frac{\partial J^*(\mathbf{x}^*(t), t)}{\partial t}$ $J_x^* = \frac{\partial J^*(\mathbf{x}^*(t), t)}{\partial \mathbf{x}^*}$

This equation, in general, is a *nonlinear partial differential equation* in J^* , which can be solved for J^* . Once J^* is known, its gradient J_x^* can be calculated and the optimal control $\mathbf{u}^*(t)$ is obtained.

So, we got $\frac{\partial J^*}{\partial t} + \mathcal{H}(\mathbf{x}^*, \frac{\partial J^*}{\partial \mathbf{x}^*}, \mathbf{u}^*, t) = 0$ because \mathbf{u} is replaced by the optimal value of \mathbf{u} equals to 0 this is nothing but my HJB equation and what was the boundary condition $J^*(\mathbf{x}^*(t_f), t_f) = S(\mathbf{x}^*(t_f), t_f)$. So, this means I have to solve this equation subjected to the boundary condition given by $J^*(\mathbf{x}^*(t_f), t_f)$ and this terminal cost is known to me.

So, with the known terminal condition I have to solve this HJB equation, this equation in more general form we also write as $J_t^* + \mathcal{H} = 0$ where J_t^* is $\frac{\partial J^*}{\partial t}$ and J_x^* here is $\frac{\partial J^*}{\partial \mathbf{x}^*}$ it is a non-linear partial differential equation in J^* which can be solved for the J^* this means we can find out the optimal cost once J^* is known $\frac{\partial J^*}{\partial \mathbf{x}^*}$ means that gradient can be calculated and by this we can also find out the can find out the optimal value of the control.

So, we have the application of the HJB equation to solve the optimal control problem. So, this lecture I stop it here. And in the next lecture, we will discuss about how we can implement the HJB equation to determine the optimal control value.

Thank you very much.
