Lecture - 23
Problem on Signal Geometry

So, let us have some interactive problem solving sessions by students who have taken this course. So, you will see some illustrations and examples into problem solving which is useful to understand and digest the concepts learnt during the lectures.

I am taking PhD student at IISC. So, today we are going to see look into a problem that discusses the signal classification. So, we have studied signal geometry in the class. So, we are going to apply it for some kind of a practical example. So, here we have a source that transmits one of the 4 signals; S 1, S 2, S 3 or S 4. So, it transmits one at a time.

(Refer Slide Time: 00:51)

The image shows a screenshot of a Notepad window titled "Notes - Windows Journal". The text is handwritten and reads:

Question:
A source transmits one of the four signals $\{s_1(t), s_2(t), s_3(t), s_4(t)\}$
where $s_i(t) = \sqrt{2} \cos(2\pi t - \theta_i)$ $i = 1, 2, 3, 4$ & $\theta_1 = \frac{\pi}{4}, \theta_2 = \frac{3\pi}{4}, \theta_3 = \frac{5\pi}{4}$ & $\theta_4 = \frac{7\pi}{4}$.
Signal $s_i(t)$ is transmitted with probability p_i , $p_1 = 0.1, p_2 = 0.2, p_3 = 0.3$ & $p_4 = 0.4$.

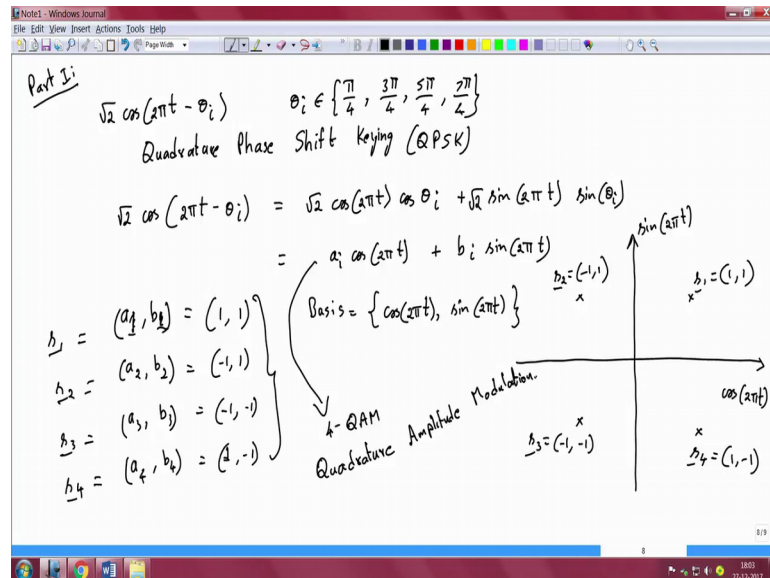

- 1) Choose an appropriate basis to represent the signals as points in the corresponding signal space.
- 2) Let the channel be noisy, resulting in independent Gaussian noise $\sim N(0, \sigma^2)$ added to each co-ordinate in the chosen basis. Identify the decision boundaries in the signal space to classify the received noisy signal.

Where each signal S_i is given by a cos signal $\cos 2\pi t$, but shifted by different phases. So, the first signal is offset by $\pi/4$, the second one by $3\pi/4$, third one $5\pi/4$ and fourth one by $7\pi/4$. So, and each of these probability signals are transmitted with certain probability either 0.1, 0.2, 0.3 or 0.4 respectively. So, the question here we have is; so, we have these signals and the question asks us to represent these signals using appropriate basis in a signal space and the second question second

part of the question; it asks us to identify the regions within the signal space in order to make a proper classification of a signal. So, we will get into the details of this question.

So, first part one.

(Refer Slide Time: 01:53)

So, notice that the signal $\sqrt{2} \cos(2\pi t - \theta_i)$ and θ_i , they belong to $\pi/4, 3\pi/4, 5\pi/4$ and $7\pi/4$. So, these signals these are called quadrature phase shift key in signals of QPSK. So, we can actually expand this cos term as $\cos \theta_i$ as $\sqrt{2} \cos(2\pi t) \cos \theta_i + \sqrt{2} \sin(2\pi t) \sin \theta_i$.

So, this $\sqrt{2}$ is missing. So, this can be written as $a_i \cos(2\pi t) + b_i \sin(2\pi t)$ where the coordinates a_i, b_i depending on the phase shifts we can write them as $(1, 1)$ or I would say a_1, b_1 as $1, 1$, a_2, b_2 is $-1, 1$, a_3, b_3 is $-1, -1$, a_4, b_4 is $1, -1$ and if you notice this signal is written as a summation of 2 orthogonal signals $\cos(2\pi t)$ linear combination of signals other than signals $\cos(2\pi t)$ and $\sin(2\pi t)$ and in fact, you can easily verify that $\cos(2\pi t)$ and $\sin(2\pi t)$ also normals signals also that is energy each of the signals is one.

So, essentially here we have the basis is nothing, but this $\sqrt{2} \cos(2\pi t)$ and $\sqrt{2} \sin(2\pi t)$ and these form the signal points I can call them as S_1, S_2, S_3, S_4 . So, these 4 forms a

points in the signal space. So, in order to visualize what it means here we have $\sin 2\pi t$ $\cos 2\pi t$ we have S_1 equal to 1 comma one S_2 is minus 1 comma 1 S_3 is minus 1 comma minus 1 and S_4 is 1 comma minus 1.

So, this represents the signal space that we have signal space and the 4 signals S_1, S_2, S_3, S_4 ; they represented as points in this particular signal space. So, now, moving to a quick comment, here this particular form is called a quadrature amplitude modulation here we have 4 points. So, it is called 4 QAM. So, now, moving to the part 2.

(Refer Slide Time: 06:51)

Part 2 With noise, the received signal $\hat{s} = (x, y) = (a_i + n_x, b_i + n_y)$
 where $n_x, n_y \sim \mathcal{N}(0, \sigma^2)$

For maximum a posteriori probability (MAP) detection,
 we want to identify signal \hat{s}_i for which
 $P(\hat{s}_i | \hat{s}) = \frac{P(\hat{s}_i) P(\hat{s} | \hat{s}_i)}{P(\hat{s})}$ is maximized for $i=1,2,3,4$
 i.e. $\frac{P(\hat{s}_i) P(\hat{s} | \hat{s}_i)}{P(\hat{s}_i)}$ is maximized.
 We know, $P(\hat{s}_i) = P_i$
 $P(\hat{s} | \hat{s}_i) = P(x = a_i + n_x, y = b_i + n_y) = P(n_x = x - a_i, n_y = y - b_i)$
 $= P(n_x = x - a_i) P(n_y = y - b_i) = \frac{1}{4\pi\sigma^2} e^{-\frac{(x-a_i)^2}{2\sigma^2}} e^{-\frac{(y-b_i)^2}{2\sigma^2}}$

The diagram shows a 2D coordinate system with four points labeled $\hat{s}_1, \hat{s}_2, \hat{s}_3, \hat{s}_4$ in the four quadrants. Each point is surrounded by a dashed circle representing a Gaussian noise distribution centered at that point.

So, with noise, the received signal you can write. So, if x comma y are the values, they are going to be of the form a_i plus n_x or comma B_i plus n_y where n_x and n_y are Gaussian noise samples with 0 comma sigma square 0 mean and Variance sigma square.

So, essentially what it means is we have these 4 signals S_1, S_2, S_3, S_4 ; however, because of this noise each coordinate, there is going to be some noise that gets added. So, the actual received samples may will not fall exactly at this basis, but it could be anywhere outside it could be issue it at somewhat like this. So, if we plot all these received samples, it forms a cloud centered around these individual points S_1, S_2, S_3 and S_4 . So, for optimal detection, what we need to do is we need to maximize a posteriori probability. So, this is a criteria that we choose. So, we need to;

So, essentially we want to identify a signal S_i for which its posterior probability given by probability of S_i given the signal which is given by probability that using Bayes theorem we write it as probability of S given as i times probability times S_i by probability of S is maximized.

So, what it essentially means is we have received a signal S and we want to maximize this a posteriori probability for different choices of i and see which signals maximizes this a posteriori probability and that that signal is that we will make. So, that is optimalization. So, essentially because of the denominator is same for all i 's we want to maximize probability of S given S_i hence probability of S_i is maximized. So, we know here in order to compute these we have a probability of S_i equal to p_i the values are given and in order to compute this probability of S with this other term.

So, we just expand it. So, probability of S given S_i is nothing, but probability that x is a_i plus n_x comma y is B_i plus n_y . So, which we can write it as probability that the noise sample n_x is nothing, but x minus a_i and the noise sample in the y coordinate is nothing, but y minus B_i and we know this it was given that these noise samples n_x n_y are independent. So, we can write them as probability of n_x probability n_x equal to x minus a_i p times probability n_y equal to y minus B_i and using the Gaussian distribution we can just write them as $\frac{1}{\sqrt{2\pi}} e^{-\frac{(x - a_i)^2}{2\sigma^2}}$ times $\frac{1}{\sqrt{2\pi}} e^{-\frac{(y - B_i)^2}{2\sigma^2}}$.

So, this gives us the terms that we that are involved in computing this a posteriori properties and towards making the decisions. So, now, consider the decision boundary between 2 signals.

(Refer Slide Time: 12:30)

The decision region for the signal s_1 is where

$$p(s_1|b_1) P_r(b_1) > p(s_i|b_i) P_r(b_i) \quad i = 2, 3, 4$$

all hold true. Similarly for s_2, s_3 & s_4 .

Consider the decision boundary $B_{ij}(x,y)=0$ between s_i & s_j given by

$$B_{ij}(x,y) = p(s_i|b_i) P_r(b_i) - p(s_j|b_j) P_r(b_j) \quad i \neq j$$

$$B_{ij}(x,y) = -B_{ji}(x,y) \quad i \neq j$$

$$D_1 = \{ (x,y) | B_{12}(x,y) > 0 \} \cap \{ (x,y) | B_{13}(x,y) > 0 \} \cap \{ (x,y) | B_{14}(x,y) > 0 \}$$

$$B_{ij}(x,y) > 0 \Rightarrow \frac{1}{\sqrt{2\pi}} e^{-\frac{(x-a_i)^2}{2\sigma^2}} \frac{1}{\sqrt{2\pi}} e^{-\frac{(y-b_i)^2}{2\sigma^2}} \times p_i > \frac{1}{\sqrt{2\pi}} e^{-\frac{(x-a_j)^2}{2\sigma^2}} \frac{1}{\sqrt{2\pi}} e^{-\frac{(y-b_j)^2}{2\sigma^2}} \times p_j$$

$$\text{Take } \ln \Rightarrow -\frac{(x-a_i)^2}{2\sigma^2} - \frac{(y-b_i)^2}{2\sigma^2} > \ln \frac{p_j}{p_i} - \frac{(x-a_j)^2}{2\sigma^2} - \frac{(y-b_j)^2}{2\sigma^2} \quad a_i^2 = a_j^2 = 1$$

$$\Rightarrow \frac{1}{2} (x-a_i)^2 - \frac{1}{2} (x-a_j)^2 + \frac{1}{2} (y-b_j)^2 - \frac{1}{2} (y-b_i)^2 > \sigma^2 \ln \frac{p_i}{p_j} \quad b_i^2 = b_j^2 = 1$$

So, the decision boundary or let us say we call the decision region. So, the decision region for the signals let us see the pick S 1 a particular signal S 1 is where this probability that we have written down earlier times probability that S 1 is greater than the same probability for any other signal S i for all.

So, whenever these conditions hold true for all i equal to 2, 3 and 4 we say that the received signal S is very we make a decision to receive a signal S is based on the signal S one. So, similarly we can extend it for other signals this definition S 2 S 3 and S 4. So, now, based on this inequity that we have we can define a decision boundary between the 2 signals. So, essentially this B i j of x y it forms a decision boundary we can is given by. So, I say B i j equal to 0 is a boundary between with between signals S i j and S i S j regions which is given by B i j x comma y which is nothing, but I just take this up difference between these 2 terms probability times S i minus probability S probability S j and looking at this we can easily say that B i j of x comma y is minus of b j i of x comma y. So, this is for all i not equal to j.

So, what this essentially means is the decision region for the signal S 1 is the intersection of all these sets or all these basis B 1 2 x comma y greater than or equal to 0 or I will just stick to inequality intersection x comma y B 1 3 is greater than 0 intersection x comma y B 1 4 x comma y is greater than 0. So, this is essentially decision region for the signal S 1. Similarly we can define the decision region for S 2, S 3 and S 4, it is going to be in the

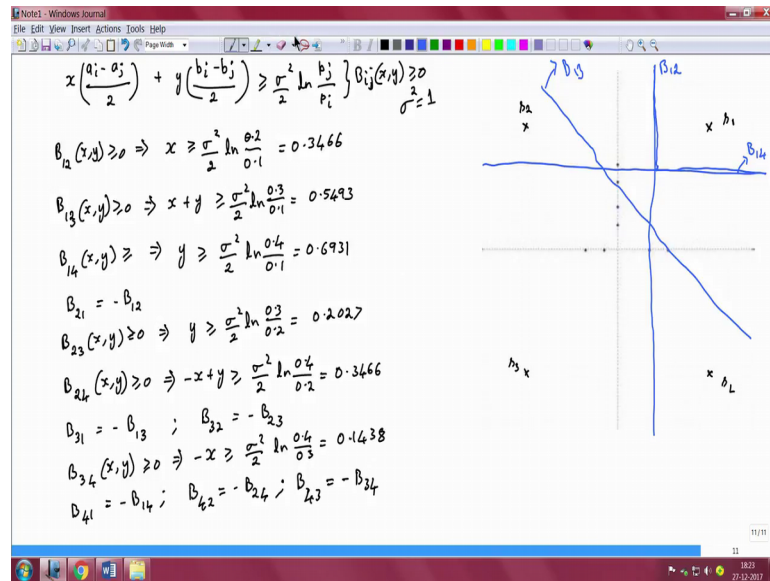

signal form where it is going to be the intersection of 3 sets now to conclude this part we have to compute this decision boundaries. So, let us look at this condition $p_i \geq p_j$ x comma y is greater than 0. So, I compute these terms or I substitute this from our earlier derivation.

So, we have one by root $2\pi e$ power minus x minus a_i whole square by $2\sigma^2$ times one by root $2\pi e$ power minus y minus B_i whole square by $2\sigma^2$ times probability of x_i is p_i minus the similar term for S_j x minus a_j whole square by $2\sigma^2$ tends one by root $2\pi e$ power minus y minus b_j whole square by $2\sigma^2$ is a times p_j is greater than 0 or I will just say this. So, we take log. So, what we get on both sides.

So, what we get is. So, these terms cancel out here and p_i instead of p_j it is sorry it is p_j and taking log of them we have minus x minus a_i whole square by $2\sigma^2$ minus y minus B_i whole square by $2\sigma^2$ is greater than logarithm of p_j by p_i minus x minus a_j whole square by $2\sigma^2$ minus y minus b_j whole square by $2\sigma^2$. So, this further can be written as half of x minus a_j whole square minus half of x minus a_i whole square. So, I am just rearranging these terms and multiply it both the sides by σ^2 plus half of y minus b_j whole square minus half of y minus B_i whole square is greater than $\sigma^2 \log p_i$ by p_j .

So, this is what we have and further simplifying. So, also note that a square is same as a j square; say equal to 1. Similarly B_i square equal to b_j square equal to 1 because a_i and a_j are either plus or minus one. So, certain all this terms a_j square a_i square b_j square B_i square and x square from both these terms. So, all of them get cancelled out and you will be left with a linear equation which will be of the form x times a_i minus a_j by 2 plus y times B_i minus b_j by 2 is greater than equal to $\sigma^2 \log p_j$ by p_i .

(Refer Slide Time: 20:30)

So, this is nothing, but $B_{ij}(x,y) \geq 0$. So, this is the decision boundary between the signal i and j .

So, we will just come substitute these points. So, for that; I mean to demonstrate that I brought this graph paper. So, we have the signals S_1, S_2, S_3 and S_4 . So, let us look at each individual boundaries. So, if we look at B_{12} if we look at the boundary $B_{12}(x,y) \geq 0$ this is given by.

So, between the signals 1 and 2 the only x coordinate changes and y coordinates are the same. So, essentially B_{12} and B_{21} are the same, but a_1 and a_2 are different and hence will be left with just a term x is greater than $\frac{\sigma^2}{2} \ln \frac{p_2}{p_1}$ is point 2 by point one and let us assume σ^2 equal to 1.

So, we will use this for convenience of plotting. So, this comes out 2.3466. Similarly, we compute the boundary between one 3 implies. So, here a_1 and a_2 ; a_3 are different B_{13} and B_{31} are also different. So, we will have both x and y terms is greater than or equal to $\frac{\sigma^2}{2} \ln \frac{p_3}{p_1}$ by 0.1. So, this comes out to 0.5493 $B_{14}(x,y)$.

So, between 1 and 4, only the B_{14} and B_{41} are different a_1 and a_4 are going to be the same. So, we will have only the y term is greater than $\frac{\sigma^2}{2} \ln \frac{p_4}{p_1}$ by point one this comes out 2.6931 instead of taking these values.

So, that I can plot here; I will show you and we know that $B_{2,1}$ is same as $B_{1,2}$ with a negative sign and $B_{2,3}$ x comma y. Similarly following the same procedure we have between 2 and 3 only the y coordinate is different. So, if you have we have y is greater than sigma square by 2 logarithm of ratio of the probabilities which is 0.3 by 0.2 and this comes out 2.20 to 27.

Similarly, $B_{2,4}$ between 2 and 4 both x and y coordinates are different and if you substitute you will get this and for 3 one we know it is B a negative of one 3 and $B_{3,2}$ it is negative of 2 3 and $B_{4,2}$. So, between 3 and 4 it is only the x coordinate that is different. So, you will have minus x greater than or equal to sigma square by 2 logarithm of point 4 by point 3 which is 1438 and for 4, it can be computed from the remaining boundaries. So, we have 4 one is minus $B_{1,4}$ $B_{4,2}$ is minus $B_{2,4}$ $B_{4,3}$ is minus $B_{3,4}$. So, all these terms are already computed here all these boundaries. So, let us plot these boundaries one by one individually.

So, I will use a different color. So, let us look at $B_{1,2}$. So, $B_{1,2}$ is x greater than equal to 0.34 or x equal to 0.3466. So, the boundary looks like this $B_{1,2}$. Similarly let us look at $B_{1,3}$ x plus y is 0.5493. So, boundaries going to look like this and $B_{1,4}$ is y greater than or equal to 0.6931. So, these are the boundaries that we have and we classify the signal as S 1 when it lies within the intersection of all these boundaries. So, essentially it is this region. So, so for that what I will do is; yeah essentially it is this region let me remove the unnecessary boundaries that are not in use.

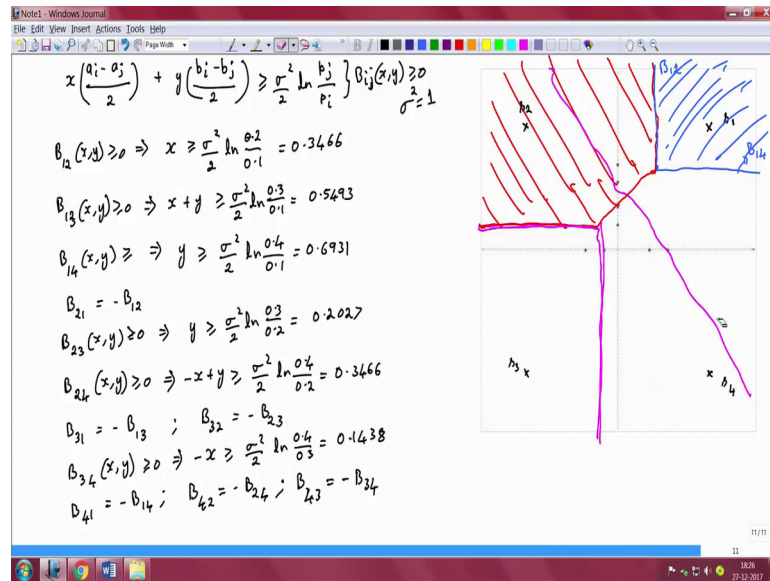

(Refer Slide Time: 27:10)

So, this is the decision region for S one. So, let me share it a bit. So, this is the decision region for S 1. Now similarly for we can continue this for S 2. So, between 1 and 2, we have this boundary that is already present and between 2 and 3. So, we have it is greater than 0.2027. So, it is going to look like this and between 2 and 4, it is minus x plus y is 0.3466 it is going to look something like this and the intersection of all these regions is going to be this.

So, let me re and some of the other boundaries they are not necessary. So, I will just erase these extra portions of the boundaries. So, this red portion that gives the decision boundary for S 2.

(Refer Slide Time: 28:44)

So, this is for S 2 similarly for S 3, I will use a different color. So, between S 2 and S 3 we already have this boundary between S 3 and S 1, we have a boundary which goes like this and between S 3 and S 4 the decision boundary is 0.1438. So, it is minus x is greater than or is equal to 0.1438. So, it is going to look like this.

So, now the intersection of all these regions is essentially this. So, let me remove again the unnecessary boundaries that we saw yeah. So, this is the decision region for S 3.

(Refer Slide Time: 30:22)

And remaining space is decision region for S 4. So, this gives the decision boundaries for various signals S 1, S 2, S 3 and S 4 within the signal space that we have seen. So, yeah.

Thank you.
