Lecture – 57
Structure of subspaces in MRA

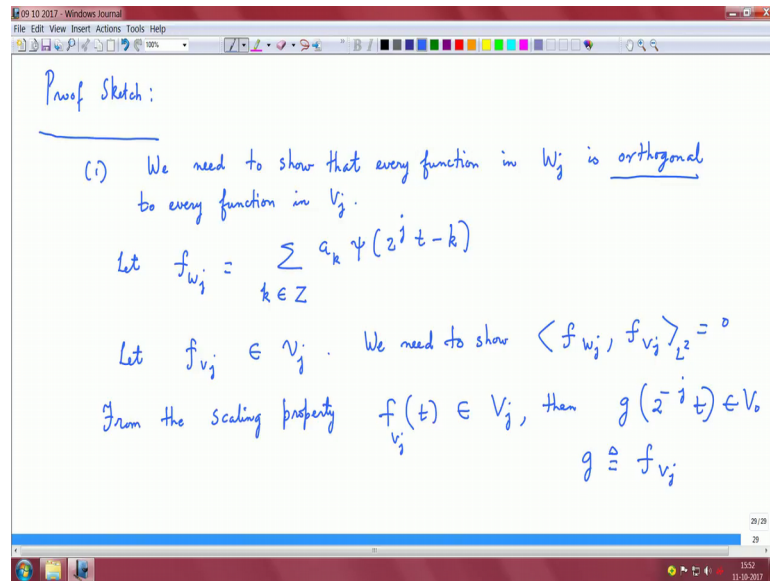

Let us get started with some properties into wavelets and these properties will essentially help us for a wavelet decomposition forwarding decomposition using wavelet discrete wavelet transforms ok. So, we start with this theorem.

(Refer Slide Time: 00:36)

So, let w_j be the space of all functions such that $\sum_{k \in \mathbb{Z}} a_k \psi(2^j t - k)$, this is the function is described by this form and a_k s are basically real numbers. So, we need to show that w_j is the orthogonal complement of v_j in v_{j+1} and then v_{j+1} is basically written as v_j direct sum with w_j .

(Refer Slide Time: 01:14)

So, I will go with a proof sketch for one of the parts and for the other part I will leave this as an exercise and we can discuss the solution to the exercise. So, for the part one; we need to show that every function in the w_j space is orthogonal to every function in the v_j space.

So, let us start with some typical function in the w_j space and let that function be f_{w_j} which is summation k belonging to some set of integers $a_k \chi_{2^j t - k}$ this is basically a linear combination of the shift orthonormal wavelets in this scale right in the j th scale.

Now, let some function f_{v_j} belong to v_j space, right, then what we need is we need to show that f_{w_j} and f_{v_j} their inner product is 0 in the L^2 space, right, I mean this; their inner product is basically 0 now from the scaling property. So, if f_{v_j} belongs to v_j , then basically let me just denote this in simple form as some f and some g here.

So, f_{v_j} of t if this belongs to v_j , then if I just call this simple function as say g like f_{v_j} is g , then I would say g of $2^j t$ belongs to v_0 and called g is basically synonymous to my f_{v_j} I am getting rid of this v_j . So, that it does not confuse as much; I could call them g and f , but I just put these subscripts v_j and w_j to indicate what spaces will it belongs to ok. So, by the scaling property this belongs to v_0 .

(Refer Slide Time: 05:51)

Consider

$$\int_{-\infty}^{\infty} \sum_{k \in \mathbb{Z}} a_k \chi(t-k) g(2^{-j}t) dt = 0 \quad \left(\because \chi \text{ is orthogonal to } V_0 \right)$$

CHANGE OF VARIABLE
 $t' = 2^{-j}t$
 $dt' = 2^{-j}dt$

$$\Rightarrow 2^j \int_{-\infty}^{\infty} \sum_{k \in \mathbb{Z}} a_k \chi(2^j t' - k) g(t') dt' = 0$$

$$\Rightarrow \int_{-\infty}^{\infty} f(t') g(t') dt' = 0$$

So, any $g \in V_j$ is orthogonal to $f \in W_j$

Now, consider there is integral minus infinity to plus infinity sigma k belongs to z a k chi of t minus k now we will just translate everything in the scale for j equal to 1 right. So, now, this times g of 2 power minus j times t; let us consider this inner product and this is 0 because chi is orthogonal to v 0, right, it is orthogonal to the functions in v 0, now this implies I want to simplify this further. So, what I would do is I would define a variable t dash is to power minus j times t.

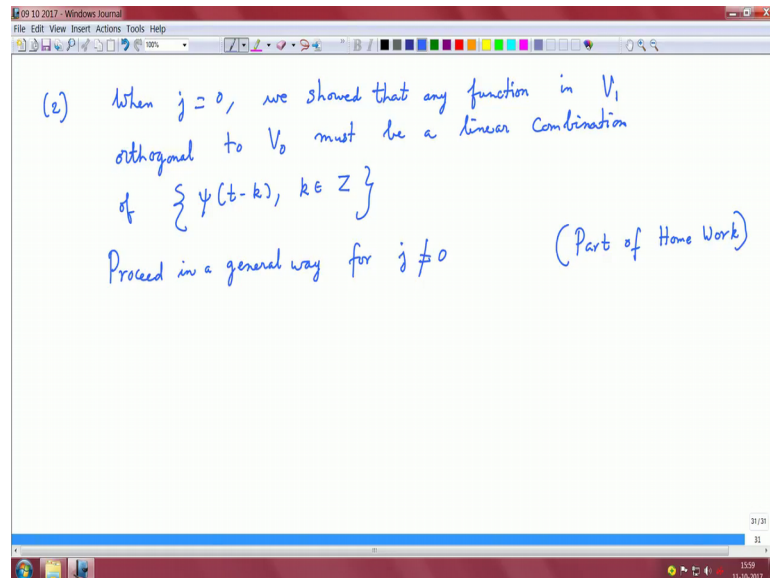

So, just focus on this I do a change of variable here; so, when I say t dash is 2 power minus j t when I let this change of variable d t dash is 2 power minus j times d t right. Now, I can rewrite this integral slightly differently this is going to be 2 power j times integral minus infinity to plus infinity summa k belonging to z a k chi 2 power j t dash minus k times g of t dash d t dash.

This is basically 0 d t is 2 power j times d t dash. So, therefore, this 2 power j is pulled outside here ok; now what we do is; so, this would imply integral minus infinity to plus infinity I can pull the 2 power j outside. So, let me call this function as possibly f of t dash, right, I call this as f of t dash just for simplified notation this is f of t dash times g of t dash d t dash and this is 0.

So, this implies any g belonging to v j is orthogonal to some f belonging to the space w j ok, this is a straightforward result, there is nothing out there, basically, we use the

definition of the inner product figure out what functions reside in what space and then we just expand using the basis in that space and then through the property.

(Refer Slide Time: 10:45)

So, this is pretty straightforward, now for the second part; I will give you the idea and I believe this deliberately as a homework. Now, when j equals 0, we showed that any function in v_1 orthogonal to v_0 must be a linear combination of basically these shift orthonormal wavelets, you saw that example and from an example basically, you have to formalize this result and then proceed in a general way for j not equal to 0 and fill in the missing gaps ok.

So, now, with this we will have we will we will establish another lemma and probably that lemma might be useful for you in this proof let me sketch that statement.

(Refer Slide Time: 13:02)

Lemma: Let $f_l = \sum_k a_k \phi(2t-k) \in V_1$
 $f_l \perp V_0$ i.e., to each of $\{\phi(t-k)\}_{k \in \mathbb{Z}}$
 iff $a_1 = -a_0, a_3 = -a_2, \dots$

Proof: $\phi(t-l) = \phi(2t-l) + \phi(2t-l-1)$ — (1)
 Consider $\langle \sum_{k \in \mathbb{Z}} a_k \phi(2t-k), \phi(t-l) \rangle$ — (2)
 Use (1) in (2)
 $= \sum_{k \in \mathbb{Z}} a_k [\langle \phi(2t-k), \phi(2t-l) \rangle + \langle \phi(2t-k), \phi(2t-l-1) \rangle]$
 $\Rightarrow a_l + a_{l+1} = 0$ by $\delta_{k-l} = 0, 1, 2, \dots$ and $\delta_{k-l-1} = 0$

Let f_l be summation over k of $a_k \phi(2t-k)$ and this belongs to V_1 , right, this is some function in V_1 this function f_l is orthogonal to V_0 that is to each of the shift orthonormal scaling functions if and only if this property holds $a_1 = -a_0, a_3 = -a_2, \dots$. So, let us see the proof of this lemma.

Now, $\phi(t-l)$, this is basically the scaling function in V_0 which is time translated, this can be written using the scales in the V_1 space as $\phi(2t-l) + \phi(2t-l-1)$. Now, let us consider the inner product of summation k belonging to \mathbb{Z} of $a_k \phi(2t-k)$ with $\phi(t-l)$. So, what we need is if f_l is orthogonal to V_0 .

Then this property must hold so; that means we should consider the inner product set that to 0 and then examine what we can; now let us look at the inner product of f_l with $\phi(t-l)$. So, this can be written as $\sum_{k \in \mathbb{Z}} a_k \langle \phi(2t-k), \phi(t-l) \rangle$ because not we can exchange the summation I mean you we have studied this property of inner products.

So, you can exchange the summation and then you can take the inner product of $\phi(2t-k)$ with $\phi(2t-l)$ because I expand it let us say if I say this is equation work say this is equation 2, I say use 1 in 2, right, then I could do this way plus the inner product of $\phi(2t-l-1)$ with $\phi(2t-k)$.

When these terms really look ugly, but you know it is very easy to simplify them now just ponder at this inner product here both of these are boxcar functions L^2 space, but with different time translates and they exist when k and l coincide.

So, basically, this can be written as δ_{k-l} when k equals l it exists otherwise it vanishes similarly you look at these inner product this is basically existing when k coincides with $l+1$ right and this can be written as δ_{k-l-1} now these are this is a summation on the outside you have some a_k s and then you have deltas and they will exist only when k equals l here.

So, therefore, you land up with a trivial statement that $a_{l+1} + a_{l+1}$ is 0 this implies $a_{l+1} + a_{l+1} = 0$. So, it will again l equals 0, 1, 2, dot dot dot and I think I should write this be equated to 0 because this is where we start with a condition that f one is orthogonal to each of three of $t-k$ now there is at least one existential result here you can figure out what is one nature of this function f_1 , if it has to be orthogonal to v_0 .

So, hopefully, you will use this property in proving the result which I gave you as a homework for part b.
