Art and the Brain
Part – 1

(Refer Slide Time: 00:18)

Trapped in a daydreaming loop

- Patients with unresponsive wakefulness syndrome (UWS), patients in a minimally conscious state (MCS), and healthy controls – compared for Brain differences along this gradient of consciousness.
- Inability among most unresponsive to “de-activate” their default network.
- These poor subjects were trapped within a daydreaming loop, unable to exercise their executive regions to pay attention to the world outside.
- Problems with deactivation of the default network observed Alzheimer’s & schizophrenia → end result is that their mind’s eye is always focused inwards.

Now, why am I talking about this day dreaming thing, because sometimes day dreaming can become pathological; that, you stay in your default mode network. And it happens to some people who have some mental illness. For example, people who have schizophrenia, you heard of disorders like schizophrenia, they stay in that default mode network; and, they cannot come out and access what is happening in the real world.

(Refer Slide Time: 00:45)

Get better at being bored

It's not enough to simply daydream.

Letting mind drift off is easy part. Much more difficult (and more important) is maintaining a touch of meta-awarenessif you happen to come up with useful new idea while in shower or sitting in traffic you're able to take note; the breakthrough isn't squandered.

Instead of completely zoning out, work on staying a little more self-aware, so there's still some activity in executive areas of the brain.

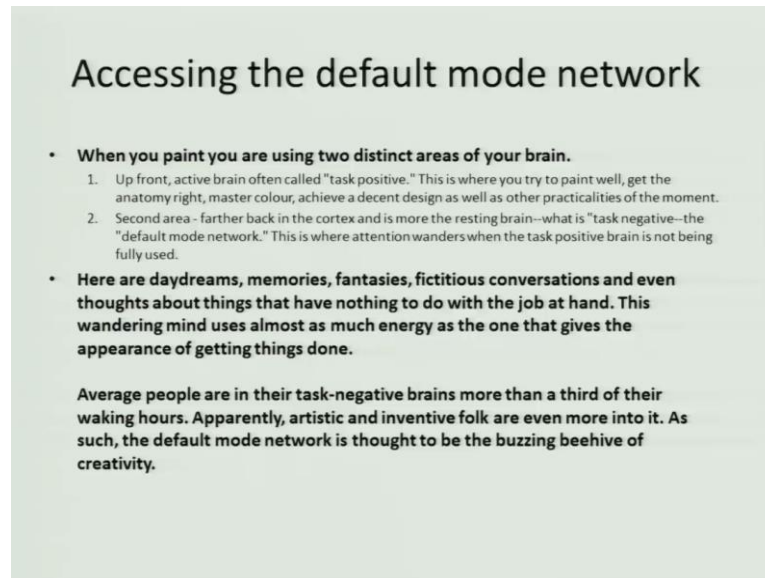

Ennui is a cognitive gift, but must be properly unlocked.

We can get better at being bored!!!

But, what might interest you is, how you can get better at being bored, how can you get bored more efficiently. Now, it is not simple enough, not enough to simply daydream, you know, letting the mind drift is the easy part, you know. Much more difficult is to maintain a touch of awareness that is called meta-awareness, see what has happening more or less.

And, if you happen to come up with something useful in your daydreams, come back to reality and say, you know what, that make sense, that is write it down or let us you know put a yellow posted note and that is very important. So, whole thing are annoying, which is why I am bored is a gift, but it is only a gift if you are able to do stop, start, and you are able to have some amount of control over it. So, as create a people, that is a gift that you must exercise and you need to learn how to turn it, off and on.

(Refer Slide Time: 01:51)

Accessing the default mode network

- **When you paint you are using two distinct areas of your brain.**
 1. Up front, active brain often called "task positive." This is where you try to paint well, get the anatomy right, master colour, achieve a decent design as well as other practicalities of the moment.
 2. Second area - farther back in the cortex and is more the resting brain--what is "task negative--the "default mode network." This is where attention wanders when the task positive brain is not being fully used.
- **Here are daydreams, memories, fantasies, fictitious conversations and even thoughts about things that have nothing to do with the job at hand. This wandering mind uses almost as much energy as the one that gives the appearance of getting things done.**

Average people are in their task-negative brains more than a third of their waking hours. Apparently, artistic and inventive folk are even more into it. As such, the default mode network is thought to be the buzzing beehive of creativity.

So, we can actually get better at being bored; how do we do that? That is something that painters have learnt to do. You know, when you are, when I am talking about these parts of the brain activity, when you paint, you are using 2 distinct areas of the brain – one, in front, is called the task positive. I know what I am doing. You know, when I am drawing a line, every part of my brain, especially the frontal part is telling me, that ok I am drawing it straight, am I drawing it straight, right; standing in front of you, this part is controlling here.

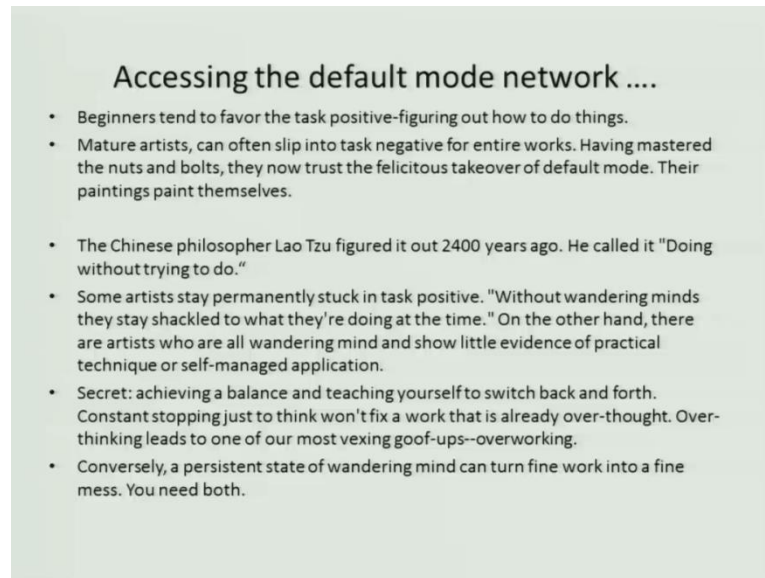

And yet, there is a part behind which is called the task negative whose job is to say, you know what this line is actually part of a tree. Because, the task negative is the part of the brain where the attention wanders, and here are the day dreams, memories and fantasies that we have. So, it is necessary to be aware of that, while one is drawing. I am sure, all you design students do that all the time, that you are using both parts of your brain; you are wandering from one to the other.

You are, when you are doing something, you are aware of, where it needs to be, how it needs to be, how precise it needs to be. But, you have a meta thinking that it needs to be part of a bigger story, right. I am standing here, part of my brain is saying, am I doing the right thing, am I saying the right words; did I say the last sentence, is it a continuation of what I am going to say next.

And yet, this one part of my brain saying, why am I talking to all these people, what is the larger picture that I want to give, does it relate to what I know; so as creative people,

when you get bored, you need to learn to do both of this. I will come back to how one does that.

(Refer Slide Time: 03:57)

The slide has a light green background and a black border on the right side. The title is centered at the top. Below the title is a list of seven bullet points.

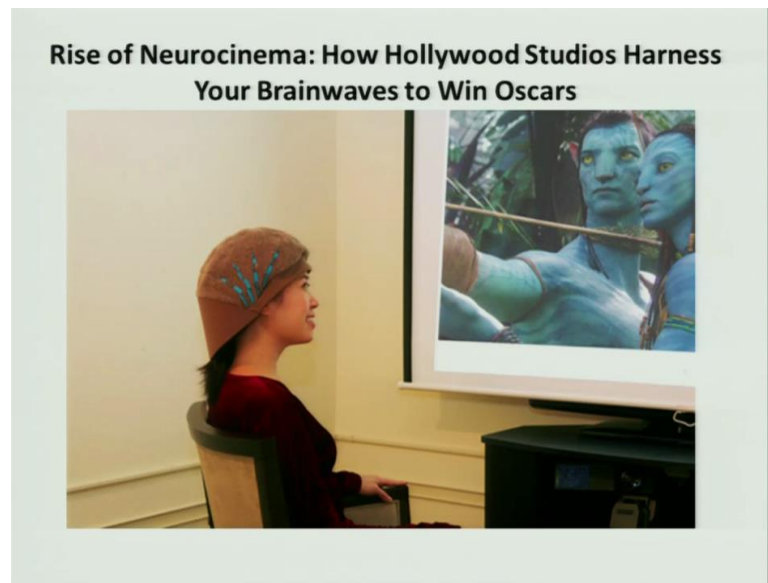

Accessing the default mode network

- Beginners tend to favor the task positive-figuring out how to do things.
- Mature artists, can often slip into task negative for entire works. Having mastered the nuts and bolts, they now trust the felicitous takeover of default mode. Their paintings paint themselves.
- The Chinese philosopher Lao Tzu figured it out 2400 years ago. He called it "Doing without trying to do."
- Some artists stay permanently stuck in task positive. "Without wandering minds they stay shackled to what they're doing at the time." On the other hand, there are artists who are all wandering mind and show little evidence of practical technique or self-managed application.
- Secret: achieving a balance and teaching yourself to switch back and forth. Constant stopping just to think won't fix a work that is already over-thought. Overthinking leads to one of our most vexing goof-ups--overworking.
- Conversely, a persistent state of wandering mind can turn fine work into a fine mess. You need both.

This line, the Chinese philosopher Lao Tzu called it, "Doing without trying to do". Sometimes you try to do too much, and there are people who spend a lot of time in draftsmanship, in penmanship; they get 2 precise in that and then they cannot go back to the task positive, that the task negative.

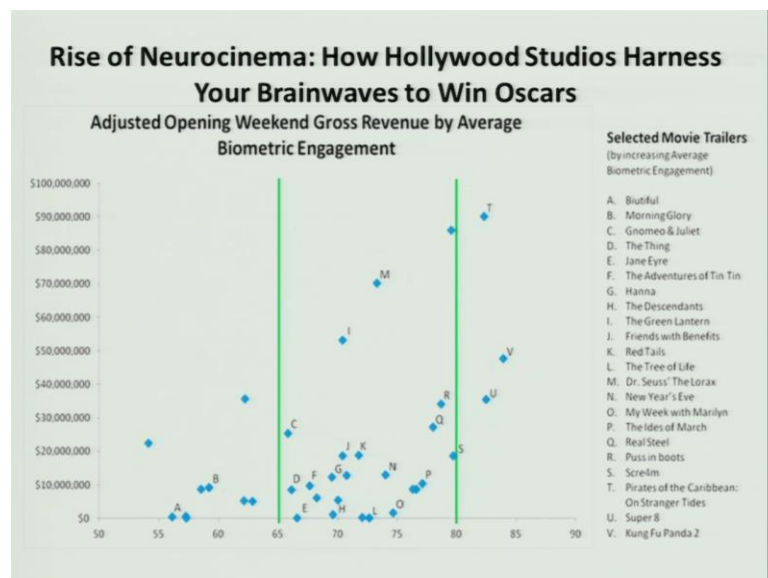

There are some people who are trying to do abstract thought without doing the task positive; and, they cannot use the task positive. And so what happens is, you know, backward clouds they create, but it is not a painting. And then, there are some people who do precise things and it is not a painting, it is just a technical drawing. So, for creative people, one needs to know how to go back and forth.

(Refer Slide Time: 04:56)

I will just end this portion with something that, you know, I found fascinating, some of you guys do cinema; are you aware of something called neurocinema? And that, bolly, hollywood is now using neurocinema to try and see whether their films will be successful or not. It started out very early, it is infancy, and I am just mentioning it as a joke to you guys.

(Refer Slide Time: 05:21)

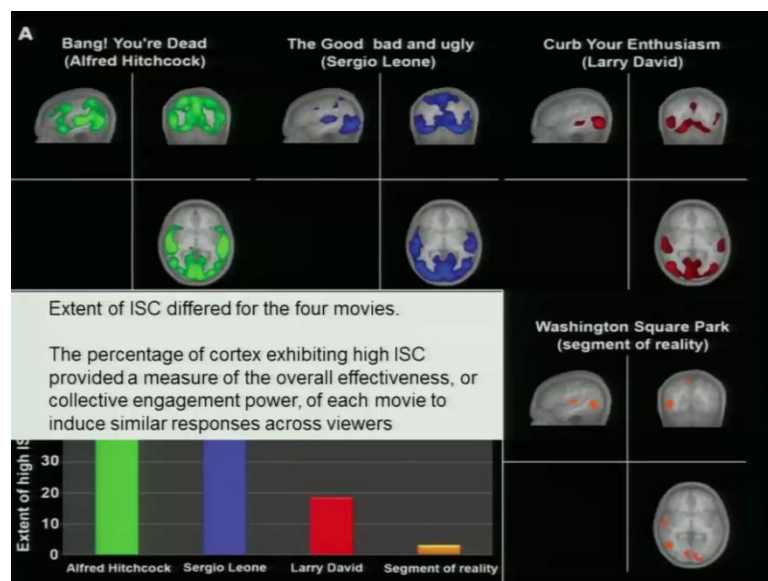

But, what they found is that, they could, using these principles, predict the gross revenue of the films, as to whether film [fl], this is something all the bollywood producers are worried about know; he put in so much, there is going to be run or not.

(Refer Slide Time: 05:42)

So, how they do it is, they show people a film. And then they basically look at, how people, the target audience reacts to the film. And they worked out certain co ordinates which is called inter subject correlation; that is, suppose they are 5 people, do all 5 respond to the film in the same way? Let me just show you examples.

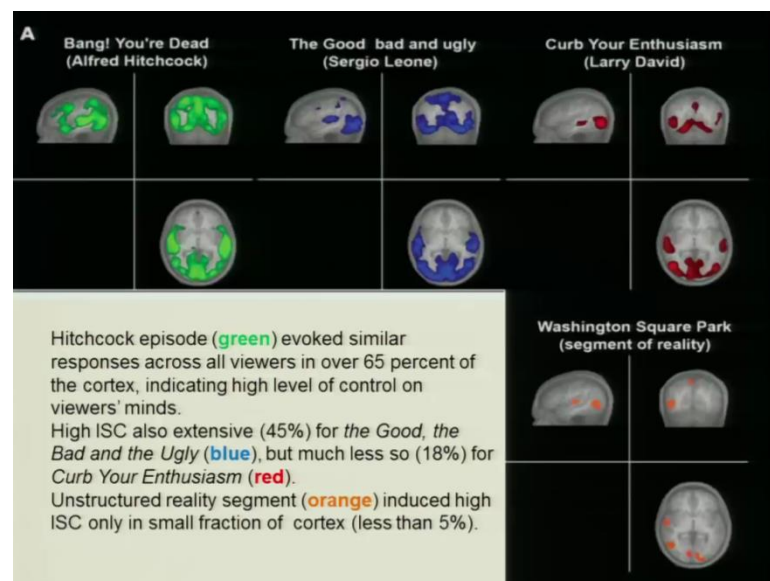

(Refer Slide Time: 06:13)

This is a response to an Alfred Hitchcock film. This is the extent of the involvement across, so if, I think, they use some 10 people. And they found that there was a commonality of activity. This was the commonality of activity to good, the bad and the ugly, you have seen that film. This was the commonality of activity to comedy TV serious called cubby or enthusiasm; some of you might have seen it. And this was the activity to an unstructured documentary, shot in Washington square; just they kept the camera there, and then they shot it.

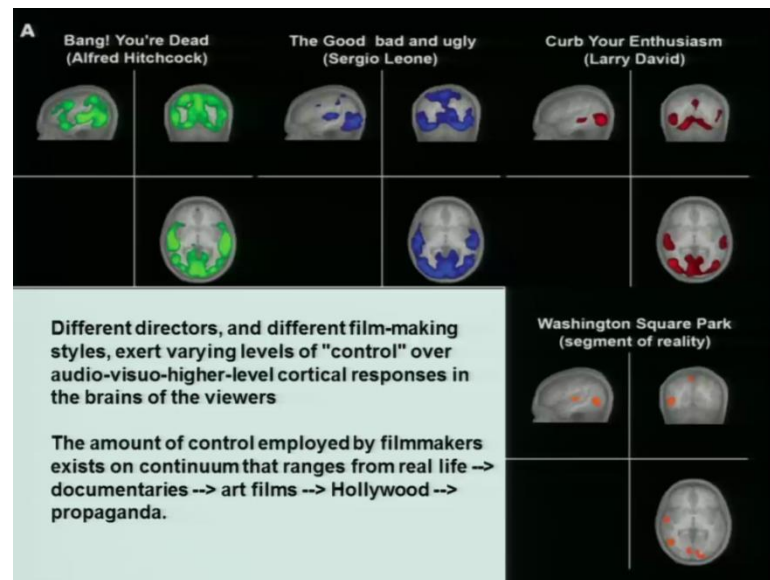

As you have seen, people responded much more to this particular film, to the Alfred Hitchcock film, which the guys who did these experiments said, this is understandable; Alfred Hitchcock catches your thing, and it is very well constructed. So, the extent of the ISC differed for the 4 movies. The percentage of the brain, exhibiting high ISC, provided a measure of the overall effectiveness or collective engagement power, of each movie to induce similar responses to other viewers.

(Refer Slide Time: 07:49)

So, like I said, you know, I have already explained that the Hitchcock got the greatest number of, I mean, the greatest amount of response indicating a high level of control on the viewers mind. And this had the lowest level of control on the viewers mind.

(Refer Slide Time: 07:59)

So, different directors, and different film making styles, apparently exert varying levels of control over the cortical response of the brain responds of viewers. Now, the amount of control what these guys are saying, this is very early earn. I cannot really say that this is established.

What these guys are saying, this is the amount of control employed by filmmakers exists on continuum that ranges from real life, least amount of control, to a well scripted Hollywood film where every line, every comma, every breath, is scripted. And if it is, then it is more likely to catch hold people's imaginations.

What I am going to talk about today is, basically about how the human brain perceives art; why does it, why does the human brain create art, how it looks at art, how does it process art. And you know, I am at the end of the day a clinician, so the question that I ask myself is, can one use art as a window to the troubled mind; and, most important is, can we use art to heal.

(Refer Slide Time: 09:24)

Art in human life

- Human beings in every culture seek out variety of experiences classified as “aesthetic”—activities linked to perception of external objects, but not to any apparent functional use these objects might have.
- Looking at paintings, listening to music, or reading hedonic experiences in which humans consistently choose to engage.
- Relevant objects in and of themselves - have no immediate or direct value for survival or for the satisfaction of basic needs (food, shelter, reproduction), they nevertheless attract great value within human culture.
- What are the neural underpinnings of aesthetically moving experience?

So, I will try, and answer some of these questions from recent research that has been done. But, when you look at art, you are aware that the human beings in every culture have sort out a variety of experiences which have been described as aesthetic, which have been linked to perception of external objects. People have looked at paintings, listen to music, there is even art in cooking and tasting; but, what are the neural underpinnings? What are the brain underpinnings of say, listening to music or looking at a work of art?

(Refer Slide Time: 10:07)

Q1. How does art and aesthetics spring from the brain?

Three areas of interest: (1) Representation, (2) Emotion, and (3) Creativity.

- 1. Representation -how the brain transforms perceptual inputs into mental representations – images, musical structures, etc.**
 - Since the different art forms – visual art, music, literature, dance, etc. – target different perceptual systems most researchers tend to focus on only one modality, especially vision or music.
- 2. Emotion - (1) How are emotions emulated by works of art?
(2) How brains attach an aesthetic value to works of art?**

Art has human emotional life as its topic –ability to induce these emotions in the viewer. Ability of works of art to activate the brain’s emotional system is central to art. At the same time, art also activates the brain’s reward system, giving rise to such emotional reactions as feelings of beauty, ugliness, fascination, etc.
- 3. (artistic) Creativity**

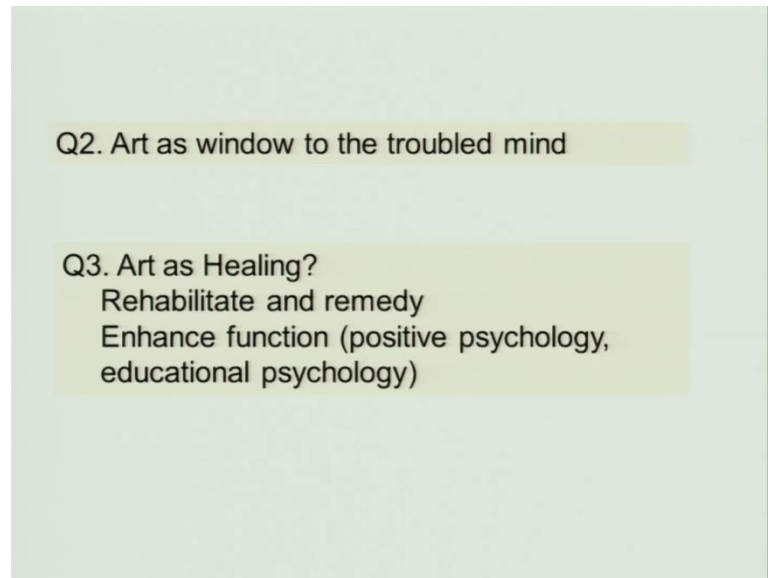

So, the question number 1 is, how does art and aesthetics spring from the human brain? You know, why am I talking mostly about humans, because we are not really sure, whether dogs and cats appreciate art. To the best of my knowledge, they do not create art. Although, sometimes, you would read of some elephant which is been taught to use a brush and splash paint and then you sell the painting at huge price, but still the juries doubt as to whether that really is art.

So, the 3 areas have interest are representation, emotion and creativity. How does one represent something, that one sees or experience, through the form of a painting, through music, etcetera? The second is, how does a work of art evoke certain emotion in you? And the third one is, of course, about creativity; you know, I might draw and paint, but if I am not creative it is not really going to evoke emotion. And if am I try very hard to do something, and I am cannot able to do it; and, somebody else you just wake up and do something and will have this ah ah reaction and will do it; so how does that happen?

So, representation is about how the brain transforms perceptual inputs into mental representations, whether there is images, musical structures, etcetera. Emotion is, how our emotions emulated by works of art, because the greatest works of art are actually emulating some emotion. You know, when you hear a piece of music, it supposed to invoke a particular emotion in you.

And, how brains attach in esthetic value to works of art? I might draw painting, but you see Picasso's painting and you will say, wow; you certainly pay much more for Picasso's painting than you will for mine, is it not? So, how do brains attach importance to that? And third is, of course, about creativity, artistic creativity.

(Refer Slide Time: 12:09)

The second area of question is, as I told you, I will talk about is, art as a window to the troubled mind. And the question number 3 is, whether art can used to heal, to rehabilitate remedy, to enhance function; not just necessarily people who are not well, but for people who are well, can they be made better.

(Refer Slide Time: 12:32)

So, how does art and aesthetics spring from the human brain?

(Refer Slide Time: 12:38)

Let us start off with different kinds of things, one needs to, when one talks of art, one is not really talking of great paintings, one is also talking about pretend, make believe that we do when we use a dolls and we pretend, that is really drama in the most primitive sense. When you go and see a painting and try to copy it, that is also art.

(Refer Slide Time: 13:07)

When you try to make sense out of a jumble which is a Jackson Pollock painting, you are also trying to fathom what is there; you using your brain to do that.

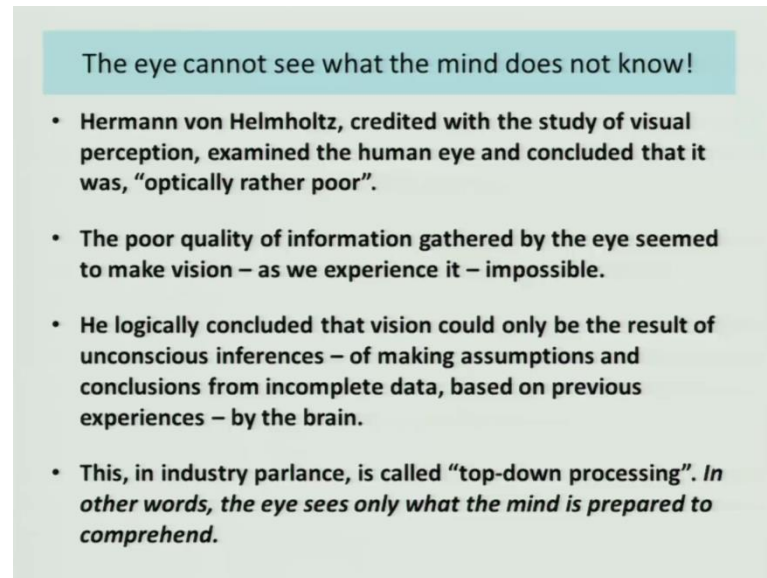

(Refer Slide Time: 13:22)

And of course, when you try and represent something, for example, this is somebody, a man, trying to imagine himself as a woman, and so therefore, wearing. You know, that there these therapy courses that are done to teach people about sensitivity, to gender sensitivity, etcetera. Sometimes you give dolls to young people and they carry these

crying dolls to their class, etcetera, to teach them how difficult it is to bring up children. So, that itself is also an art form in that sense.

(Refer Slide Time: 13:58)

The eye cannot see what the mind does not know!

- **Hermann von Helmholtz, credited with the study of visual perception, examined the human eye and concluded that it was, “optically rather poor”.**
- **The poor quality of information gathered by the eye seemed to make vision – as we experience it – impossible.**
- **He logically concluded that vision could only be the result of unconscious inferences – of making assumptions and conclusions from incomplete data, based on previous experiences – by the brain.**
- **This, in industry parlance, is called “top-down processing”. *In other words, the eye sees only what the mind is prepared to comprehend.***

But, the eye cannot see what the mind does not know, right. And basically, this is a very busy slide, but what I wanted to talk about is that, that if I do not know something exists, is it really there? Because, what you see and what I see, are different. It is the same object, this one, you know, what you see and I see are different; what you and I make out of it are different; but, we have learnt over the years to call it a pen, because, our sensory systems are different.

(Refer Slide Time: 14:49)

The Eye Sees Only What the Mind is Prepared to Comprehend

- visual system in humans allows us to assimilate information from the environment.
- The act of seeing begins when the lens of the eye focuses an image onto a light-sensitive membrane in the back of the eye called the retina.
- The interesting thing about visual perception is that what we see is not simply a translation of retinal images.

The eye sees only what the mind is prepared to comprehend. And we spent many years trying to understand that. But, having said that, the visual system and human beings allows us to assimilate information from the environment, but it is a mechanical thing. Somewhere in the brain, these have to be put together to make a representation of what is out there, and each ones brains make a different representation.

(Refer Slide Time: 15:20)

Goldfishes in a Bowl

- Reality that we perceive, so it seems, is not quite real.
- Our view of the world is constantly distorted by something or the other, starting with the genetic and cultural dispositions that we inherit.

The goldfish views world through curved glass walls of bowl. Although object outside bowl may be moving along a straight line, goldfish will view it as moving along a curved line. Certainly, we cannot fault the goldfish for believing itself to be right or for its perception of reality.

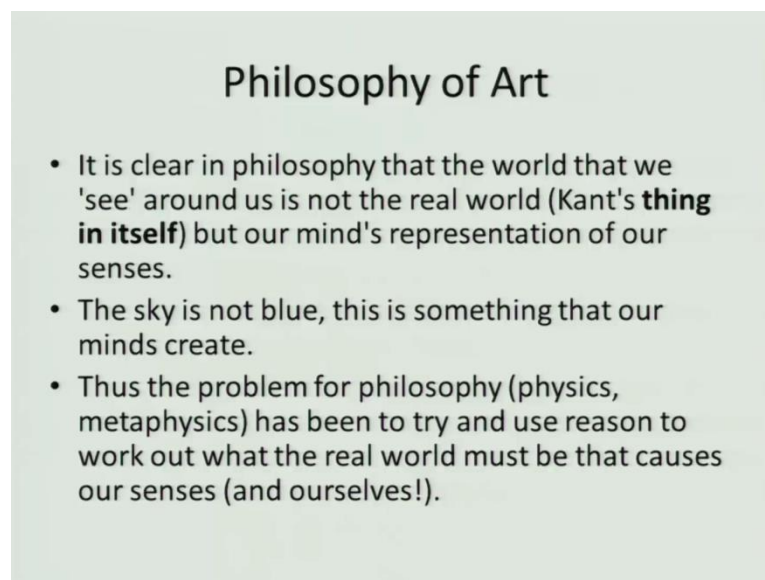

So, it is like, we have like, goldfishes in a bowl. Reality that we perceive is not quite real. You know, this is, we have gone into the field of philosophy, but our view of the world is

constantly distorted by something or the other, starting with our genetic makeup, without cultural predispositions, etcetera. For example, in some primitive societies, they cannot count upto 10; they count in units of 5. So, their perception, the world is based on their cultural, a cultural knowledge.

And, the classic thing which I will talk about later is, if we go and play a sitar to a foreign audience who having ever heard of a sitar or Indian music, they will probably describe it as screeching sound; they will not be able to perceive the beauty of it. You will be able to perceive the beauty of it because your culture has programmed you to understand the nuances of this cluster of sounds.

(Refer Slide Time: 16:36)

The slide is titled "Philosophy of Art" and contains three bullet points. The text is as follows:

- It is clear in philosophy that the world that we 'see' around us is not the real world (Kant's **thing in itself**) but our mind's representation of our senses.
- The sky is not blue, this is something that our minds create.
- Thus the problem for philosophy (physics, metaphysics) has been to try and use reason to work out what the real world must be that causes our senses (and ourselves!).

So, it is clear that the sky is not really blue, it is just that; that is what our minds create out of our perceptions. For some people whose minds cannot create it, they often see the sky is red or whatever color, you know, people who are were color blind, which is where we come to the ancient Sanskrit word of, rasa.

(Refer Slide Time: 16:55)

- 'Rasa,' in ancient Sanskrit means 'capturing the very spirit of something, the soul of something in order to evoke a specific mood or sentiment or emotion in the viewer's mind.'
- So the idea of art is to change the image in some way to more optimally titillate these 30 visual areas of the brain and excite visual emotions."

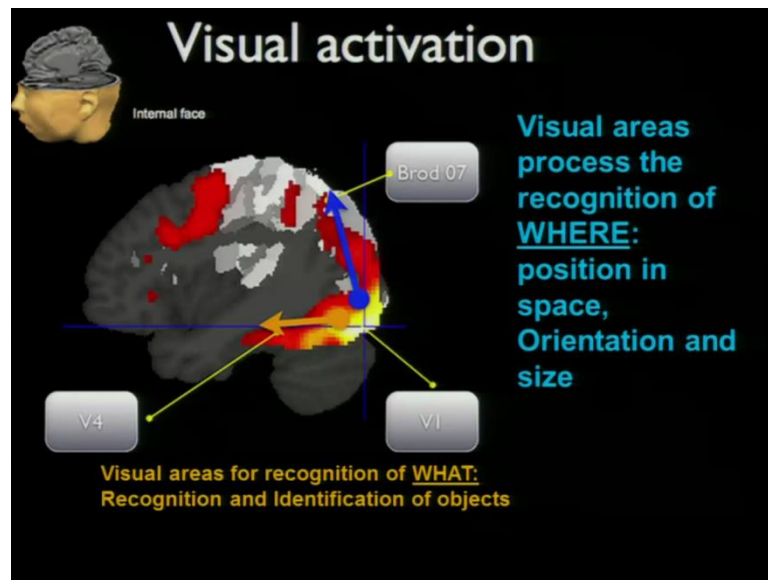

Rasa is to take, to insipitate, to squeeze out the meaning, and that is what the human brain does best; it gathers information, it gathers perceptions, and squeezes out a meaning.

(Refer Slide Time: 17:20)

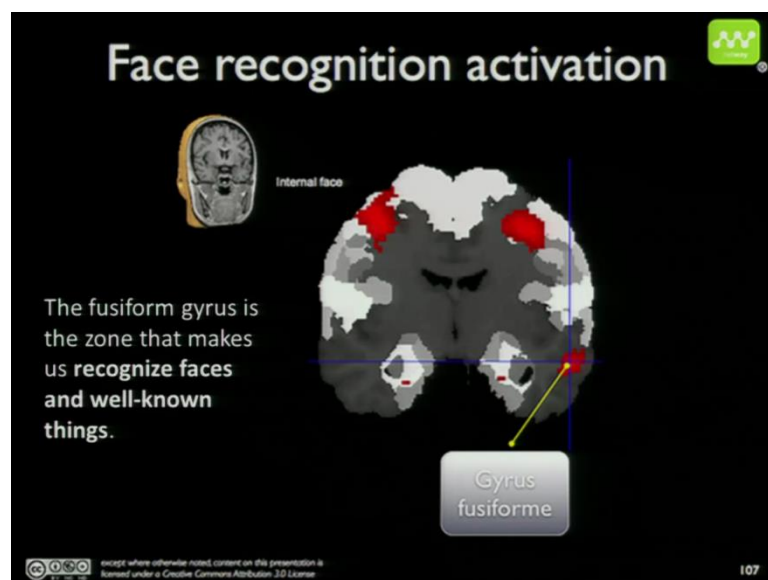

Let me go past. This is the picture of an antelope. You know why we see it? Because, as a part of evolution, parts of our brain have developed specialized forms, specialized functions to look at this special form, to recognize that this is a deer object, recognition, to detect the contour, to see the color, to see depth, but these are all done separately.

(Refer Slide Time: 18:02)

So, there are different parts in the brain; say, for visual activation. The part here, for example, in the visual area processes where, something else. These are the areas in the brain which process, what? What is this? What is this is different from where it is. You know, for people who have this area knocked out, they can say this is a moda, but they do not know how far it is.

(Refer Slide Time: 18:38)

Similarly, there are areas in the brain which are specialized for face recognition. Now, if I see, you sitting there, and have seen you earlier, all these 3 areas have to send me

information, and I have to work it out, that it is you who I seen earlier in the morning, right, sitting 6 feet away from me, and I recognize your face, but all 3 have to work together.

(Refer Slide Time: 19:10)

Then there is another area for semantic activation; that is, putting a name to it. You know, it is a great skill, putting a name to a face; it is unfortunately a skill which I am loosing very fast apart.

(Refer Slide Time: 19:28)

So, Picasso was one person who deconstructed this, the whole cubism movement. You know, by deconstructing this, space and form and contour, he used the brains ability of putting these together and by reconstructing it, to create mystery in your minds. And he very famously once said, every child is an artist. The problem is how to remain an artist once we grow up.

From the neuroscientist point of view, this is very significant because children see things differently from adults. You know how children see? Children see these different parts as different parts, and then they have to put it laboriously in their brain, they have to put it together. So, if you see how children draw, do you remember, or you do any work with children, they draw in ways which adult too try to learn how to draw. But, as they grow up this process of putting things together becomes an automatic thing.

So, the way adults see the world is very different from how the children see the world. So, for an adult to draw like a child you have to relearn the entire process. And Picasso says that, you had to relearn the entire process of looking at the world as a child and redrawing, I mean, drawings like a child. Kids see differently than adults. Kids under the age of 12 perceive visual information differently. Kids separate visual information.

The childhood methods of processing may allow kids to fine-tune their visual methods thus they grow, but once you fine-tuned it, then you have to unrefine it, to be able to see you know, when you create a work of art you have to then unrefine it again.

(Refer Slide Time: 21:33)

So, we come to how art enthralls the brain. Again, to quote Picasso, “Art is the lie that reveals the truth”. You know, just nearly representing what is, what you are seeing, is not interesting; a plain photograph is not interesting. And ever since the discovery of photography, artists has stopped representing reality, as they see it. They are trying to reconstruct, deconstruct, bend, catch the attention, you know.

There was a, you heard of E.M. Foster, the writer. He said, as far as art is concerned, whether it is literature, etcetera, there is only one thing that you need to do; he said, only connect; that is you have to, whatever you do, has to connect to a human brain. And however you do it, is actually the process of art.

(Refer Slide Time: 22:36)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

The image shows a Chola bronze statue of a woman, likely a deity or a royal figure, standing in a graceful pose. The statue is highly stylized, with a very thin waist and long, slender limbs, which are characteristic of the 'peak shift' principle mentioned in the text. The statue is set against a dark background, highlighting its golden-brown color and intricate details.

So, you heard of Doctor Ramachandran, Vilainoor Ramachandran, the fantomlim person. He and others have worked on this whole thing of neuroaesthetics, as to what is the neurology of esthetics. You know, what is esthetic, and why something is esthetic? And they worked out certain principles of why something is esthetic and why something is not, why does it catch the eye, why does it catch the human brain, why does it connect, and, some of these things that I will go through.

He says that any great work of art which is what is called a peak shift; that is, if you look at a Chola bronze, you will immediately know that this is not how real women look. Real women do not have such thin waists; they do not have such long hands; they do not have such protuberant dress, but that is what the artist does; he shifts the peak; here, she shifts the peak. The peak has been shifted; this has been shifted and immediately grabs your attention. So, that is one of the principles that artist use knowingly or unknowingly to grab the attention of the brain.

(Refer Slide Time: 23:58)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

Figure 1
A jumble of splotches or a face?

The other one is called perceptual grouping. What you see in this? Is this a jumble or splotches, or do you see a face here? Why that a face? Because, in your mind all these clutches have got grouped together and you see the face, is it not? So, this is something which the brain does, and the artist has overtime realized that if you exploit this, the brain say, wow.

(Refer Slide Time: 24:37)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

Then, the other one is contrast. This is, you know, this is pal clay. What is this? You use this and you contrast this with a different color, different temperature; and, immediately this hits you; it strikes out.

(Refer Slide Time: 24:54)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

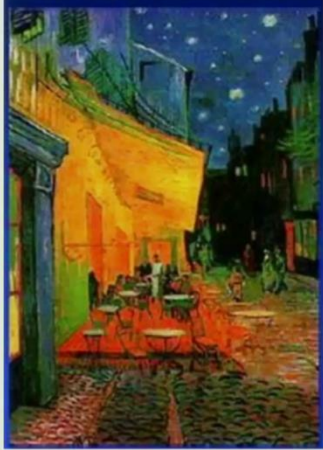

Isolation; what you see in this picture? The red dot; it is isolated. You have the splotching yellows, and you have the red dot, that isolated by the black, right.

(Refer Slide Time: 25:09)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

This is called perceptual problem solving. There are lots of things here, but he as shows it, is given to you, your brain would say, what it cannot make sense, what is this? But, then it becomes very interested and you see the yellows, you see the reds, and you see that this is a café seen. So, so on and so far, I am not going to go into all of these.

(Refer Slide Time: 25:34)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

(Refer Slide Time: 25:36)

V.S. Ramachandran's 10 principles of art

- Peak shift
- Perceptual Grouping and Binding
- Contrast
- Isolation
- Perceptual problem solving
- Symmetry
- Abhorrence of coincidence/generic viewpoint
- Repetition, rhythm and orderliness
- Balance
- Metaphor

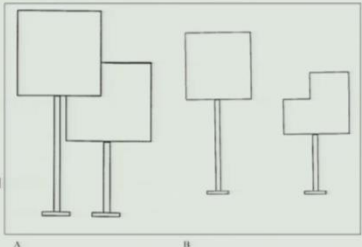

Figure 3
One square is seen as occluding the other. It is hard to see A as B viewed from a unique vantage point. The brain prefers the generic view.

There is another thing. For example, this is abhorrence of coincidence; the brain does not like coincidence. So, what is this? Is these 2 things, one behind the other, is this perspective, or is it actually 2 shapes like this. If I did not show you this, what would you think with this? One behind the other. Because, the brain does not want this; and so it automatically criticizes the letters one behind the other. This is something that artists and designers used.

(Refer Slide Time: 26:12)

So, anyway, I do not want to bore you by going through all these things, what. Again, let me give you an example in ways in which artists have learnt to hack the brain. This is Monet's field of poppies, Coquelicots. What you see? Just look very closely at the painting. No, look at the painting what is happening there. They are moving; what is moving? Not the people; if you see, the movement comes from somewhere else. No, it is the poppies which are moving, but you saw the movement, is it not? But, this will movement, Monet drew this a more 100 years ago.

Why do you see movement there? Let me do one thing. Let me take the color out. Where are the poppies? No poppies, right. Monet discovered one great artistic principle; then we bring the color back again. He actually painted these at the same color temperature. They just contrast, but the color temperature is the same. So, what happens is, the parts in our brain which seen black and white, which is the part in our brain which actually supposed to look for distance, for shape, etcetera, keeps firing and looks at it in black and white. Hence is no difference.

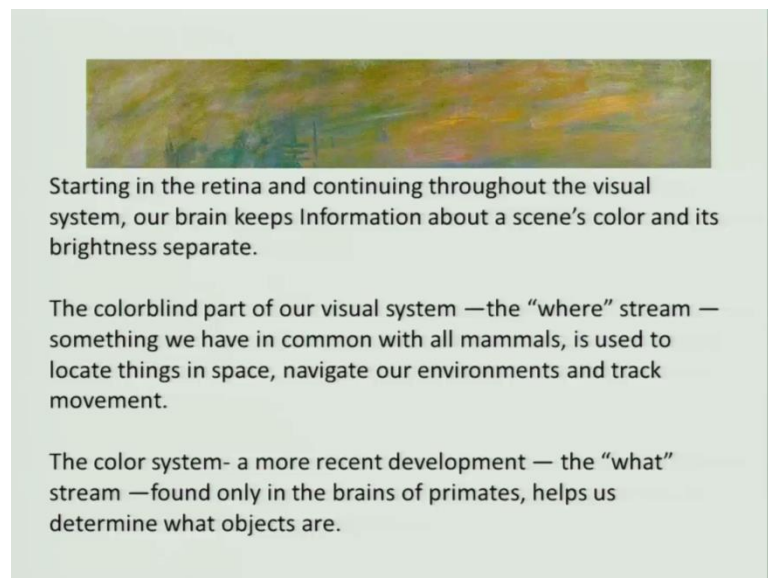

The poppy and the green fields are the same. The parts of our brain which code for color vision, fire at another time, and this is the red green, red green, red green, difference. So, your brain is moving from black and white, no difference; to color, difference. And so there is, you shifting from one to the other and you see movement. So, artists have learnt to hack it. I am sure, Monet did not know neuroscience; it is just that.

(Refer Slide Time: 28:20)

Again, this is the sunset; let me take off the color, is know, that comes back again; then you can see once you do that which seem as this moves. So, like I said, one that is like a, you actually see simultaneously one that is like a white photocopy, and other that is like a full color picture and keeps moving from one to the other.

(Refer Slide Time: 28:56)

So, starting in the retina and continuing through the visual system, our brain keeps information about the scene's color and its brightness separately. So, the colorblind part of our visual system - the “where” stream - something that we have in common with all

mammals; you know that dogs do not see color; you know, is used to locate things in space, navigate environment, etcetera.

The color system is more recent - the “what” stream - what is it. So, it is found only in the brains of primates, apes upwards; it helps us determine what this is; is this an apple or is this a poisonous berry; you know, color is very important there; that is different; so it keeps going from one to the other.

(Refer Slide Time: 29:44)

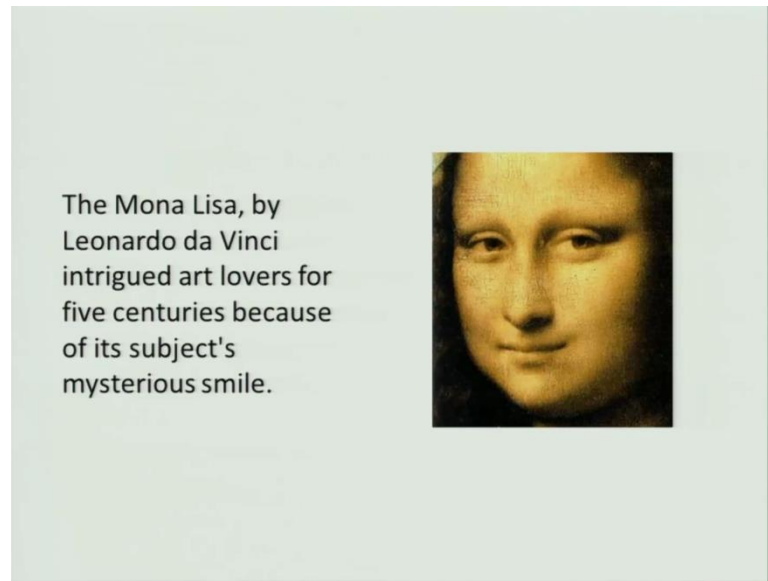

The sun and the sky have exactly the same level of brightness (luminescence), making them invisible to the parts of our brain that locate things in space.

So, while we can see the sun, it's hard to see exactly where it sits in the sky.

A lot of the motion in Monet's paintings comes from the fact he used equal luminescence, and gives Monet's work liveliness and a sense of interactivity with the viewer

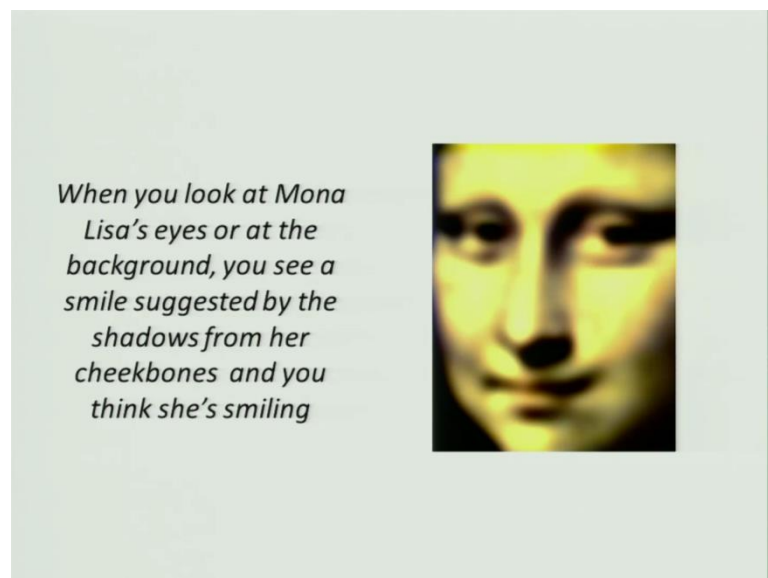

So, like I was saying, the sun and the sky have exactly the same level of brightness, luminescence, making them invisible to the parts of the brain which locate it in space. So, while we can see the sun, it is hard to see exactly where it sits in the sky. A lot of motion in Monet's paintings actually comes from this principle.

(Refer Slide Time: 30:07)

Let me go to another picture; you all know this picture, right. This is Mona Lisa, most famous painting on earth. The biggest mystery with this painting is, whether the Mona Lisa a smiling or is she frowning, right. Look at the picture, what happens? Again this movement here; you think sometimes she is smiling, sometimes she is frowning; why does that happen?

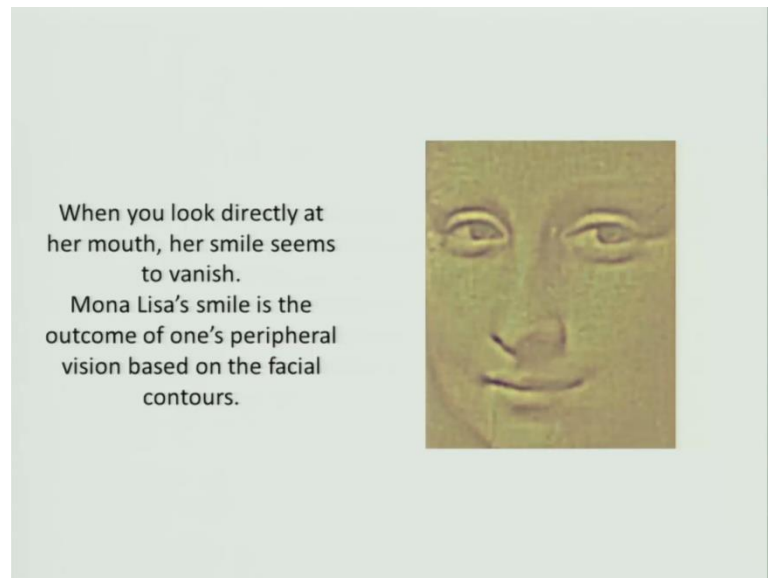

(Refer Slide Time: 30:51)

Let me again do a little bit of manipulation. I have manipulated the picture, a little bit. So, I have taken out the shading here, what do you see? When you look at the Mona

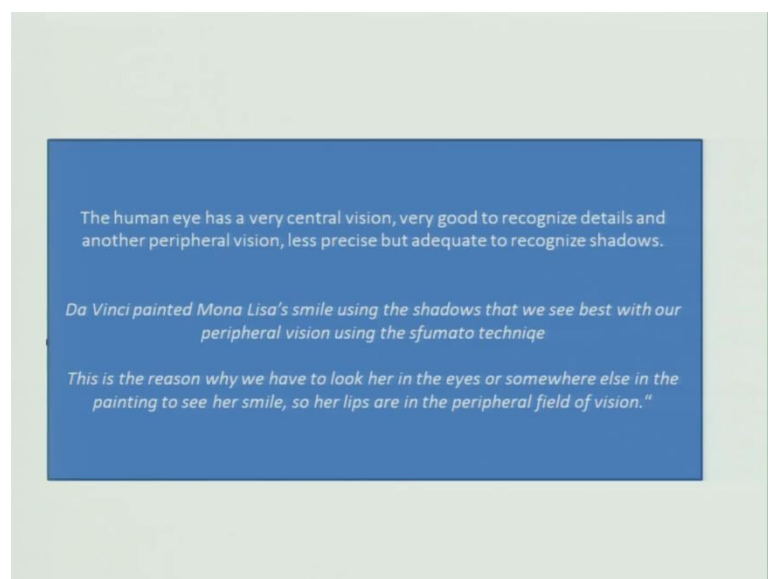

Lisa's eyes or at the back ground, you see a smile, because there is shadow under her cheekbones, right. Leonardo used a very new technique which the renaissance painters have just discovered; it was called a sfumato technique, which was the use of, using dots to make the shadow, instead of making a solid layer.

(Refer Slide Time: 31:38)

So, when you do that, when you look directly at her mouth, her smile seems to vanish because you are basing it not on this, but only on this.

(Refer Slide Time: 31:55)

The human eye has a central vision which is very good, and it is used to recognize details and another peripheral vision which is used to see shadows. Because, again, we want to see this, but I also want to see movement here because, you know, danger might be coming from there. Remember, we are not all sitting in class rooms, 40000, 50000 years back. So, we needed to see shadows moving, but you also needed to see what is right there. So, these are 2 different systems, and they work independently.

(Refer Slide Time: 32:40)

Why is Impressionist painting so popular?

- *A study of more than 90,000 people in the UK, aged 13 to 90, found that they preferred Impressionist art over cubism, Renaissance or Japanese styles*

*British Journal of Psychology, vol 100, p 501
Nature Neuroscience, vol 6, p 624*

So, artists have used these 2 different systems like, you saw in that painting; you know that Impressionist painting is most popular in the world, why? Not really; what is the thing about Impressionist painting? Some of you are art students here; gives an impression, does not give you the full details; why is it so fascinating to the human brain?

Student: It gives an opportunity to know more.

It gives you an opportunity to guess. This has actually linked to the brain early warning system. I will show you why?

(Refer Slide Time: 33:26)

Let us go to the, let me just go to the picture, and then I will come back. Let me just show you this picture first. What do you see here? This is Dalí's painting on the slave market. What do you see? That is the bust of a voltaire. So, the painting is actually called the bust of voltaire or the slave market. And your eyes go to this.

Once you discovered this, it is no longer the slave market; your face keeps, your mind keeps going back to this thing, why? Because, your, this is the mystery there. And once your brain has discovered the mystery, it keeps going back. Have you ever had a some cut in your mouth, your tongue keeps going, human brain is a very curious organ. So, once it discovers some mystery, keep going there; and coming back, going there.

(Refer Slide Time: 34:40)

Let me try and see whether, let us no, let us go to, what is this?

Student: It is a dog.

Are you sure?

Student: Yeah.

Not just leopard, but your brain has to make sense of this. Remember, you know, where this comes from; our brains are used. Human brains have had to for a long time make sense of whether that movement, is just lives moving, or it is a leopard. So, we have to develop this thing. So, the human brain is very good at sorting out mysteries, actually looks for mysteries, in our visual cues, in our music, etcetera.

So, even in music, you have something which is repetitive, your mind gets bored; you miss a beat, so your mind just says, wow, you know. And that is something that you do in art also. When you, I am, in painting, you represent something which is, we just represent the forms, you miss out the content, and becomes that much more pleasing; because, you allow the mind to recreate to, to add in the missing portions.

(Refer Slide Time: 35:52)

The Curious Brain

How magicians manage to fool the brain

The 7 Principles of Magic

- Palm:** To hold an object in an apparently empty hand.
- Ditch:** To secretly dispose of an unneeded object.
- Steal:** To secretly obtain a needed object.
- Load:** To secretly move a needed object to where it is hidden.
- Simulation:** To give the impression that something that hasn't happened, has.
- Misdirection:** To lead attention away from a secret move.
- Switch:** To secretly exchange one object for another.

And, this is something that the magicians rely on. The magicians will do something, and they will let your minds make 2 plus 2. Now, this lady is getting cut, and he will do something and you think that actually the saw is going through, when is really not happening. The slight of end that you do for cut tricks; your mind just adds up 2 plus 2 is equal to 4, because you expect that to happen.

When it does not happen, your eye is, your mind does not register, although your eye sees that. So, if you look at some of the TV magic, you will find that is, if you slow it down, you can see what is happening, but at the real place your mind is just preparing over the, ok.

(Refer Slide Time: 36:45)

The Curious Brain

- Our brains don't see everything—the world is too big, too full of stimuli. So the brain takes shortcuts, constructing a picture of reality with relatively simple algorithms for what things are supposed to look like.

*Magicians capitalize on those rules
. Tricks work only because
magicians know, at an intuitive
level, how we look at the world*

So, basically, what I am saying is, our brains do not see everything. The world is too big, too full of stimuli. So, the brain takes shortcuts, constructing a picture of reality with relatively simple algorithms for what things are supposed to look like. Magicians capitalize on these rules. Tricks work only because magicians know, at an intuitive level, how we all look at the world.

(Refer Slide Time: 37:10)

EMOTION -

- (1) How are emotions emulated by works of art?
Empathy!
- (2) How brains attach aesthetic value to works of art?

Emotion; how are emotions emulated by works of art? How brains attach aesthetic value to works of art?

(Refer Slide Time: 37:15)

How seeing a painting makes us *feel*

- What's going on in our brain when we have a strong emotional response to seeing a painting?
- This is a very old question and one that artists ask all the time. Will my painting evoke an emotional response when someone looks at it?

What is going on in our brain when we have a strong emotional response to seeing a painting? You know, artists are always asked you, guys always ask, that if I do this, a dream make somebody feel, wow.

(Refer Slide Time: 37:35)

1. Subjects told to rate a painting as 1 if they didn't like it, and 4 if they liked it a lot.
2. Looked at different paintings and gave ratings while in an MRI machine so that brain responses could be imaged.
3. When they saw a painting they liked a lot, it evoked a different response in their brains.

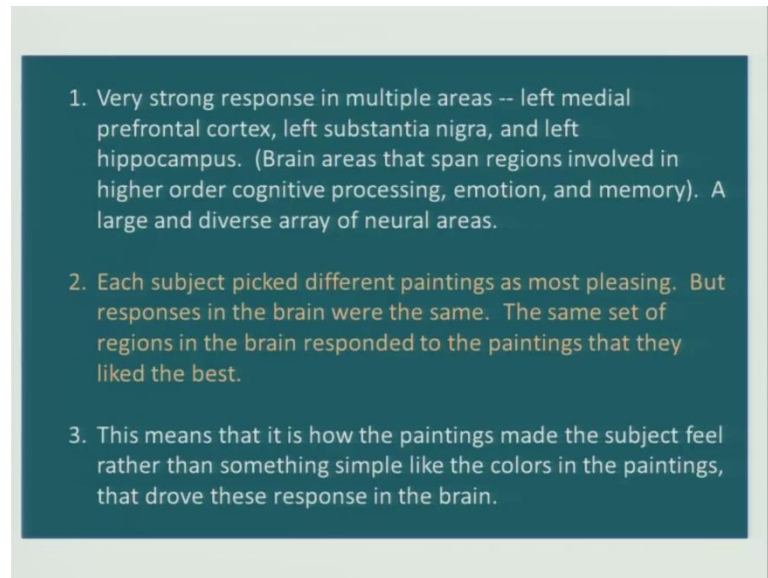

Chinese Restaurant – Max Ernst

This is the study that people did: subjects were told to rate a painting, in 1 if they did not like it and 4 if they like it a lot. They looked at different paintings and give ratings while sitting in an a line, or in an MRI machine. When they saw a painting they liked, it evoked

a different response in their brains; we all know that, is it not? This is, for example, is a expressionist painting by Max Ernst called Chinese Restaurant; and. do you like it? [FL].

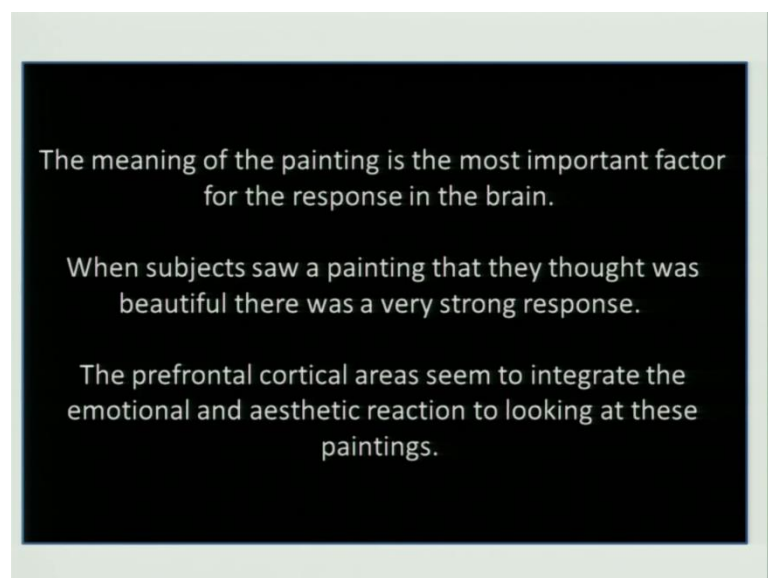

(Refer Slide Time: 38:13)

1. Very strong response in multiple areas -- left medial prefrontal cortex, left substantia nigra, and left hippocampus. (Brain areas that span regions involved in higher order cognitive processing, emotion, and memory). A large and diverse array of neural areas.
2. Each subject picked different paintings as most pleasing. But responses in the brain were the same. The same set of regions in the brain responded to the paintings that they liked the best.
3. This means that it is how the paintings made the subject feel rather than something simple like the colors in the paintings, that drove these response in the brain.

But, there was a very strong response in multiple areas in the brain when people like the painting. Each subject, there in this experiment, picked a different painting, that something as they liked. But, what is fascinating is, that some paintings made the subject feel, know, that they liked it more.

(Refer Slide Time: 38:36)

The meaning of the painting is the most important factor for the response in the brain.

When subjects saw a painting that they thought was beautiful there was a very strong response.

The prefrontal cortical areas seem to integrate the emotional and aesthetic reaction to looking at these paintings.

So, what happened was, the meaning of the painting appeared to be most important for emotional response in the brain, for people who saw. And so there were certain areas of the brain which are responsible for searching for meaning which seem to light up when they really liked a painting.

(Refer Slide Time: 39:05)

Let me show you the pictures. This is your brain on art. So, these are some of the areas where most liked, you know, increased activity rather than least like. And these are areas which are responsible for distinguishing between right and wrong. These are areas which look at error detection. These are areas which say, wow, when I have chocolate. And these are the same areas which are simulated when you look at a painting.

(Refer Slide Time: 39:43)

Areas activated in response to **aesthetic experience**

- Orbitofrontal cortex
- Cingulate gyrus
- nucleus accumbens
- Amygdala, extended limbic system
- Hippocampus, precuneus
- Visual areas

Kirk et al, 2009, Brain & Cognition
Vessel et al, 2010

This is more of the same. These are some of the areas which are activated in response to aesthetic experience. We would not go into that; this was made for a slightly more neuroscience audience.

(Refer Slide Time: 39:59)

Music & Poetry

- commonly reported response to listening to music or poetry is a shiver or a tingle down the spine. momentarily euphoric and is a physiological response to the perceptions.

Some people experience a lump in the throat or goose pimples, and in many the response is associated with tears.

Let me go, pass it an, music and poetry. Commonly reported response to listening to music or poetry is shiver, or a tingle down the spine. Some people experience a lump in the throat or goose pimples, or they get tears.

(Refer Slide Time: 40:18)

Emotional Responses to Music

- Emotional responses to music involve predominantly, right-sided neuronal circuits, with reciprocal connections between temporal and frontal structures.
- Key areas that **integrate memory, emotions, and cognition** are involved (amygdala, ventral striatum, parahippocampus, precuneus, and frontal cortex), as is the cingulate gyrus, so important for mammalian **play and bonding activities**
- Also, **music recruits the neural circuitry of the brain's reward systems (also activated by drugs of addiction), which forms part of a complex neuronal system that underpins normal social conditioning and bonding, as well**

Now, the emotional responses to music appear to occur in areas that integrate memory, emotions, and cognitions. And these are also the areas which are involved in play, in bonding, in material bonding, etcetera. So, it is not surprising that when you listen to music you get the same kind of, I am safe or I am happy, ok.

(Refer Slide Time: 40:46)

Default Mode Network

- Imaginedozing with a magazine on your lap. Suddenly, a fly lands on your arm. You grab the magazine and swat at the insect. What was going on in your brain after the fly landed? And what was going on just before?

Let we go pass this too much neurobiology here. But, imagine you are dozing with a magazine on your lap. Suddenly, a fly lands. So, what you do? You grab one magazine and swat it. But, what was going on in your mind before you did that, and what happens

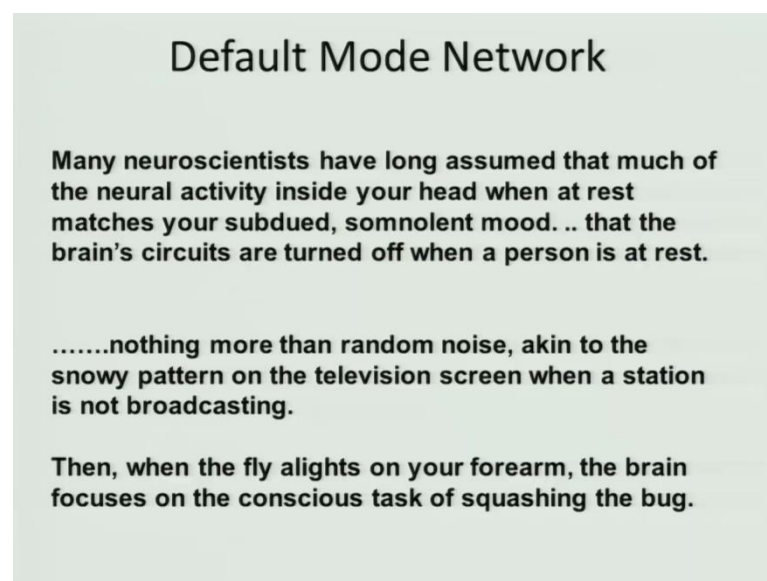

just after you do that? Now, why am I talking about this? Because, most of the time our creation is done; when do we do our creation? When our minds are active, or when our minds are passive? Actually both, what do you mean?

But, most of the time when you are doing creation, you are just flying down, what is called brown study, is it not? And then, suddenly you get an, ah hah, reaction. So, let us examine what happens there? When the mind is not working, when people are day dreaming, we are always state that the day dreaming is bad know, and people would day dream a later procrastinating, the lazy, they not doing their work, etcetera. So, what people did?

You know, there have been some people who have been working on the neurobiology of day dreaming. So, they said, ok, when the brain is not doing anything, you just lie in a scanner, do not do anything. And what they expected was, the activity in the brain would be the least; what they found, was fascinatingly wrong; that, when your brain is not doing anything, is the most active.

And, if then your brain is asked to do something, you woken up from your, then the brain has to take activity from this and devoted to something else. It is almost as if when you are doing nothing, parts of your brain are gossiping with each other and sharing information.

(Refer Slide Time: 43:02)

Default Mode Network

Many neuroscientists have long assumed that much of the neural activity inside your head when at rest matches your subdued, somnolent mood. .. that the brain's circuits are turned off when a person is at rest.

.....nothing more than random noise, akin to the snowy pattern on the television screen when a station is not broadcasting.

Then, when the fly alights on your forearm, the brain focuses on the conscious task of squashing the bug.

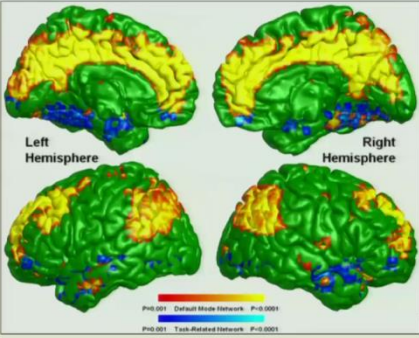

And, this is called the default mode network.

(Refer Slide Time: 43:09)

Default Mode Network

But recent neuroimaging technologies reveal that a great deal of meaningful activity is occurring in the brain when a person is sitting back and doing nothing at all.

When your mind is at rest—daydreaming quietly or asleep or anesthetized—dispersed brain areas are chattering away to one another.

And the energy consumed by this ever active messaging, known as the brain's default mode, is about 20 times that used by the brain when it responds consciously to a pesky fly or another outside stimulus.

Let me go to, these are some of the areas which are very active when you are doing nothing. And I will come back, and now, I will tell you why I brought this up.

(Refer Slide Time: 43:21)

It is like people gossiping. This is a normal Rockwell painting of people, a rumor gossip going, coming back to the same person.

(Refer Slide Time: 43:34)

Neuroscience and Theatre

"Theater is the art wherein human beings make human action worth watching."

Think seriously about the effect of an actor's action upon the nervous system of each audience member.

This slide is out of place; neuroscience and theatre, I will come back to it.

(Refer Slide Time: 43:40)

Mirror Neurons: Monkey see Monkey Do!

A group of Italian neuroscientists noticed that identical nerve cells discharged both when a monkey performs a specific action and when it observes another monkey performing that action.

Called these *mirror neurons* because of the way they apparently mirrored an observed action in the monkey's brain.

Monkey grabs peanut and monkey watching activates the same nerve pathways.

But actually, both monkeys are *doing* . One monkey is visibly making an action; the other monkey is *restraining* from making the exact same action.

The other part that I wanted to talk about neurobiology was about mirror neurons. That are something that, you know, if you get a monkey to do a particular activity say, take a banana, and you put a electrode in the brain, you can find out which area of the brain is firing. Take banana, you know, has one part of the brain working.

Now, if you give the monkey, or more pedestal, you give another monkey of banana; this monkey is take banana, part of the brain starts firing, you know; it is almost as if when I am seeing you do something, same area in my brain starts mirroring your activity.

And, this is very important in us, human beings understanding each other; how do I understand you, how do I understand that you are feeling bored right now, or that you are smiling that, you know, you are have amusement, and I can understand your amusement, I can, you know, because as soon as you are smiling, my smiling areas in the brain also get turned on. So, it is like a mirror, ok.

(Refer Slide Time: 45:07)

And, this is something that we learn to do as children. This is a famous experimental somebody did. You do this to a child, very small child, you know not children like us, very small, and the child will do it back to you. Do this, child do that at back to you. And this is Monkey see Monkey do. And we have areas in this, in the brain which are Monkey see Monkey do areas which allow us to understand other human beings, to understand.

These are called mirror neurons. And this is also very important when you create art. Because, when you see something somebody has done, you are also able to understand that. You see a picture of goya, is somebody is, you know, tearing of somebody's limb, visibly feel the pain yourself; you know, he, get in your mind and that is because artist have learned to utilize this; it is a neuroscientist are only now learning why the artist have done it, ok.

(Refer Slide Time: 46:13)

Mirror Neurons: Monkey see Monkey Do!

Mirror neurons are the cells that relate to empathy.

Via action, mirror neurons create a meaningful link between the self and the other by dissolving the boundary between the two.

When mirror neurons are activated, people feel empathy. And empathy is the baseline of the theater experience and the unspoken contract between actor and audience.

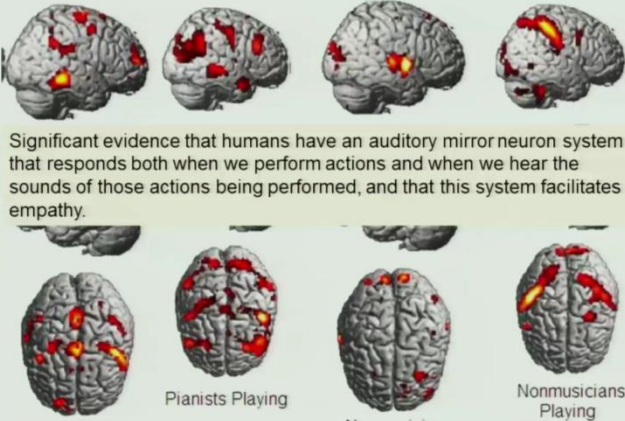

When Othello realizes his tragic mistakeer pistol, I feel myself inside of him.

This is something that we do in theatre. You know, when you see Othello killing his wife, and then say, oh my god what have I done; you know, you feel the, oh my god.

(Refer Slide Time: 46:29)

Mirror Neurons & Appreciation of Music

Significant evidence that humans have an auditory mirror neuron system that responds both when we perform actions and when we hear the sounds of those actions being performed, and that this system facilitates empathy.

Pianists Listening Pianists Playing Nonmusicians Listening Nonmusicians Playing

Bangert et al(2006). *NeuroImage*, 30, 917-926; Gazzola et al(2006). *Current Biology*, 16, 1824-1829

These are some of the mirror neurons which light up when you appreciate music. So, that is how art evokes emotion in, because somebody has put it emotionality into something, and you are able to appreciate somebody else's emotion through this something. So, it is significant evidence that humans have an auditory mirror neuron system. For example,

that responds both when perform actions and when we hear the sounds of these actions being performed.

So, if there is a musician and he sees the other musician playing, you immediately are able to do that in your mind. As a non musician, when I hear the sounds being played, I, my emotional areas raise on it at that level. And to give you an example, anybody who drives cars, is used to driving a car, you setting in the non driver seat and the other person is driving, you will see immediately the other guy brakes, your foot also goes on to the brake, you know, something like that, ok.

(Refer Slide Time: 47:50)

“..the sitar sound like a strangled cat..”

Dancers from London’s Royal Ballet and experts in capoeira, a Brazilian martial arts form known for its physical rigor and acrobatic feats.

Both groups watched videos of ballet or capoeira while hooked up to MRI scanners.

The mirror neuron system showed far more activity in individuals watching the discipline in which he or she was trained.

This demonstrates how a familiarity with the observed action stimulates more empathetic response than the less familiar action.

This is where culture comes. When the brittles were originally asked about Ravi Shankar’s sitar, they said, one of them I forget whom say, sounds like a strangled cat. But, then they came to India sat with Ravi Shankar, (Ref: 48:17) sat with Ravi Shankar, and they become great devotees.

Similarly, dances from the London Royal Ballet were shown, you seen capoeira, the martial art, dance from, you shown each other’s forms; and, the mirror neurons work better when they were shown each other’s forms, and worked less when they were shown somebody else’s form. So, culture also has a lot to do with it, ok.

(Refer Slide Time: 48:50)

Now, what next? So, basically, do not show cow your paintings; the cow does not share your mirror neurons.

(Refer Slide Time: 48:54)

(Refer Slide Time: 49:02)

(Refer Slide Time: 49:07)

Emotional significance & Aesthetic value

- Aesthetic value is influenced by context.
- Behavioural studies show that presenting artworks accompanied with titles, text, and other forms of cognitive information can significantly influence an observer's reported evaluation of the artwork

The slide features a title at the top. Below the title are two images. The left image shows a man in a black suit standing in front of a large, colorful abstract painting with red, yellow, and white tones. The right image shows a man in a dark jacket crouching on the floor, looking at a large, abstract drawing on the floor. Below the images is a bulleted list with two points.

Some of the difficulties that we have in emotional significance and aesthetic value; so aesthetic value is also influenced by context. So, if I see a Husain, a lot of it, is also related to the fact that I know it is Husain.

(Refer Slide Time: 49:14)

Emotional significance & Aesthetic value

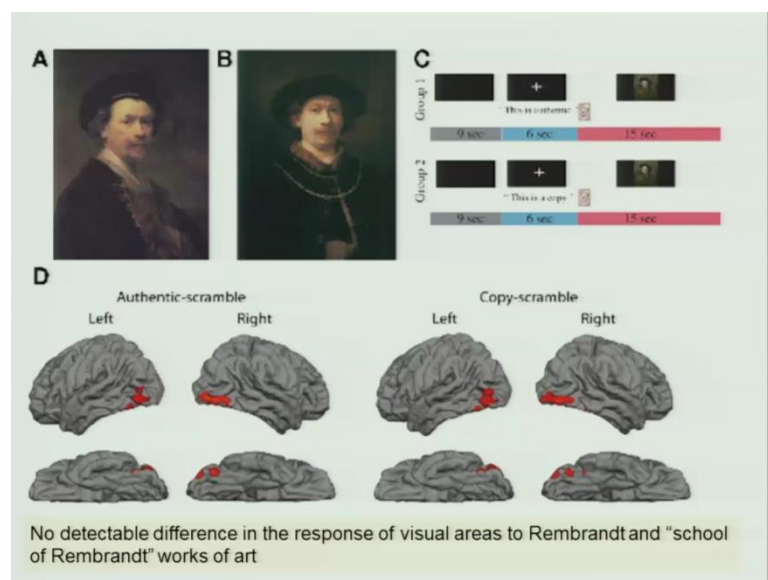

A tin was sold for €124,000 at Sotheby's on May 23 2007

- Aesthetic value is influenced by context.
- Behavioural studies show that presenting artworks accompanied with titles, text, and other forms of cognitive information can significantly influence an observer's reported evaluation of the artwork

Emotional significance and aesthetic value: a tin was sold for 124,000 Euros at Sotheby's on May 2007 containing this. So, aesthetic values strongly influenced by context. So, behavioral studies show that the presenting artworks accompanied with titles, text, and other forms of cognitive information can significantly influence an observer's reported evaluation of the artwork.

(Refer Slide Time: 49:49)

In fact, this is the study that they did. They showed Rembrandts and fake Rembrandts. And people were told this is a real Rembrandt, this is a fake Rembrandt. Sometimes, they

were told the opposite - for a real Rembrandt they were told fake, and for fake they were told real. And basically, to cut a long story short, the human brain reacts much better when you are told this is a real Rembrandt. Imagine you seeing a real Rembrandt and you told a fake, not good.

(Refer Slide Time: 50:35)

Let us go, pass this, because this is a very long lecture. So, I will, let us come to creativity. Where is creativity? Creativity is everywhere in the brain. You know, it would be nice to say, creativity occurs here. But, it is probably not; it is not monolithic; it is a culmination of many processes.

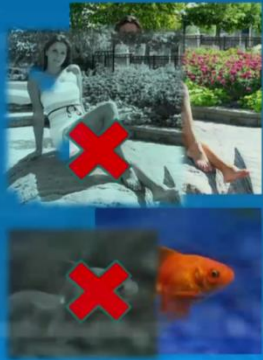

There used to be a myth that the right brain does something, left brain does something; and, there are right brainers who think differently and left brainers who think differently. What we now understand is, there is no such thing. And the right and the left have to work together to solve mathematical algorithms; and, the right and the left have to work together to create amorphous works of art.

(Refer Slide Time: 51:30)

Imagination is derived from imagery by transformation of the basic imagery.

Imagination essentially involves three steps:

1. Take a 'primary' representation (image that has truth relations to the outside world).
2. Then make a *copy* of this primary representation (a 'second-order' representation).
3. Finally, introduce some *change* to this second-order representation, playing with its truth relationships to outside world without jeopardising the important truth relationships that the original, primary representation needs to preserve.

Baron-Cohen (2007) Biology of Imagination

Imagination is derived from imagery by transformation of basic imagery. You know imagination; what is imagination? You know, you have a unique one, you have a horse with twisted horns; that is imagination. How do you put these things together? So, you have to use imagery which exists and modify it.

So, imagination involves 3 steps - one is, take a primary representation and imagine that has truth relations to the outside world. This is the girl, no doubt about it. So, my mind takes a girl. And then, this is the goldfish, right; this exists. Then what my mind does is, it makes copies of these. You know, it, for you guys it will be easy, just cut and paste. So, you take that and you paste it, in another part of your mind. So, then make a copy of this primary representation which is a second order representation.

Then, what it does, is that you knock off parts, introduce some change to the second representation, playing with its truth relationships to the outside world. But, not so much that it becomes totally un-understandable, and then put them together. So, what you get? You get this, ok.

(Refer Slide Time: 53:00)

Imagination is derived from imagery by transformation of the basic imagery.

Imagination essentially involves three steps:

1. Take a 'primary' representation (image that has truth relations to the outside world).
2. Then make a *copy* of this primary representation (a 'second-order' representation).
3. Finally, introduce some *change* to this second-order representation, playing with its truth relationships to outside world without jeopardising the important truth relationships that the original, primary representation needs to preserve.

Baron-Cohen (2007) Biology of Imagination

So, this is something that, when you are creating, you do unthinkingly, but what neuroscientist now doing is, able to track this process of how creativity occurs.

(Refer Slide Time: 53:17)

Development of imagination

Abilities to form second-order representations & distort these → Meta-representation capacity

- Ability for pretend play in 9-15 months infants and ability for mind reading or false-belief or Theory of Mind ability in older children (4 yr olds)
- Pretend play enables one to keep two copies (one primary + a false second-order representation) of an external object in mind simultaneously. Same time - enabling one to know that one is true and the other false or a pretense.
- Involves treating one object (e.g toy brick) as another object (e.g. telephone) and thus develops the capacity to distort the second order representation of an object.

This meta-representation ability in turn is the prerequisite for imagining future outcomes and thus for successful planning in older adults.

For example, development of imagination is something that does not exist in very young children, and you have to go through pretend play, to learn how to imagine, ok.

(Refer Slide Time: 53:36)

Imagination - Autism

- Children *delayed* in developing this special piece of hardware for meta-representation find it hard to mind-read others.

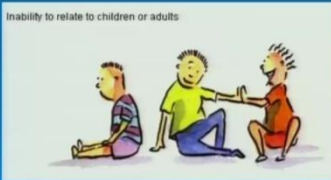

Exclusive interest in the real world, with no interest at all either in mind-reading, pretending, or fiction.

Enjoy making patterns with real objects, or watching how real objects behave, but cannot spare a thought for how someone else might be feeling or what they might be thinking, or understand why a mermaid or a unicorn is a fun idea.

Inappropriate toy play

Inability to relate to children or adults

And, some people are not able to imagine. And these are disorders of that we face. For example, children who are artistic, are not able to intimately relate to children or adults because you have to do pretend. They are able to play with inanimate objects because they lack the ability to do this pretend, they lack the ability to actually mirror neuron, to imagine what the other person is thinking; you do not have to imagine what a car is thinking.

(Refer Slide Time: 54:16)

How boredom makes us think

- When immersed in monotony- automatically lapse into a very special form of brain activity: *mind-wandering*.
- Derided as a lazy habit- kind of thinking we rely on when we don't really want to think. (Freud :“infantile” thinking!!)
- It's a sign of procrastination, not productivity!!
- Turns out - people are engaged in mind-wandering 46.9 percent of the time. In fact, the only activity in minds are *not* constantly wandering is love making.
- What's happening inside the brain when the mind wanders?

Let us go, pass this because, ok. Let me deal with this. Sometimes, most creators will tell you that the best flash of genius actually came; they were lying there doing nothing. Something flashes, you know, there is poem called the Daffodils written by Wordsworth. And Wordsworth said, it flashed upon his inward eye, while he was lying there doing nothing; watching the clouds go by, suddenly it arose in his mind.

And, boredom has always been blamed, but boredom actually makes us think. When immersed in monotony, we automatically lapse into what is called mind wandering. Now, it is always been thought as something bad. You know, Sigmund Freud say, it was infantile thinking, baby like thinking, and therefore, bad. You know, parents, throughout history has said, we should not be sitting and letting our mind wander.

It turns out, when people are engaged in mind wandering, it is a large proportion of your time that you spend mind wandering, you know; almost 50 percent of the time your mind is wandering, right. What is happening inside the brain when the mind wanders?

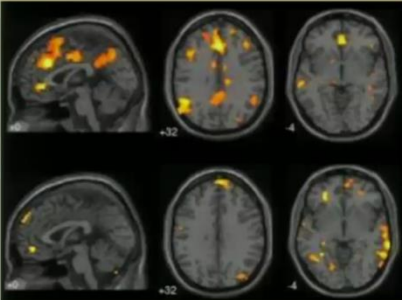

(Refer Slide Time: 55:44)

How boredom makes us think

Subjects (in fMRI) given an extremely tedious task, started to mind-wander within seconds.

Activation : in medial pre-frontal default network regions (assoc. with subjective self-reports of mind wandering & performance errors on concurrent tasks).

But this was additionally assoc. with executive network recruitment.

Activity strongest when subjects unaware of their own mind wandering, suggesting that mind wandering is most pronounced when it lacks meta-awareness.

Christoff & Schooler, 2009

So, what happens is, huge proportion of the brain is active when the mind is wandering. Remember, I showed you this, the picture of the default mode network; that is when the brain is actually talking to; you know, the parts of the brain have happily gossiping with each other; you know, picking up as to what did I know, what do I know, what have you learnt, what are you saying, and this is not in conscious, in consciousness.

As people have said, genius occurs only from a prepared mind. If you have not done a lot of perspiration before, you are not going to get that certain idea. You know, it does not come from the sky; you have to have done a lot of work and then go to sleep. So, the best way to actually create is think a lot about what you are going to do, and then go after sleep.

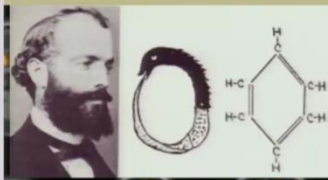

Because, if you have a, if you are trying to find a solution very hard, you will find that you cannot find the solution; 99.9 percent of the time, you cannot. Especially, when you have a thing that you have to deliver, you have to give your assignment in, you will find you just cannot do it; you are getting more anxious and anxious and anxious, but you cannot do it, right; and that is because of this.

(Refer Slide Time: 57:07)

How boredom makes us think

Mind wandering is not quite so mindless as thought!

People struggling to solve complicated problems -better off switching to a simpler task and letting mind wander.

"When you daydream, you may not be achieving your immediate goal – say paying attention in class –

but your mind may be taking that time to address more important questions in your life, such as advancing your career or personal relationships

Christoff & Schooler, 2009

Let me just take you to, how boredom makes you think. You have 2 examples - one is, of course, the, eureka, example of, was it, yes; then, this other example of guy called Federick was a Chemist who is working on this whole thing of carbon atoms, carbon. He, through all these things, he decided that there have to be 6 atoms; but how do 6 atoms fit together? And. he worked, worked in it, worked in it, worked in it, tried different kinds of things, just could put them together.

And, when he went of sleep, and in his dream he saw one snake swallowing another snake; and he woke up and said, wow, that is it; it is a ring, you know; and, that is how creativity, that is how things happen.
