Lecture – 9
Optimization Theory and Techniques Part-2

Welcome back to the lecture series on Microeconomics. Let us continue with the discussion on Optimization Techniques. Previously, we have seen a class of optimization problems which are known as unconstrained optimization. It means, that the decision variables or the choice variables we are dealing with can take any value, there is no constraint on them. But, in reality we find in many maximization or minimization type problems the decision variables are not allowed to take on just any value so; that means, that decision variables the choice variables have to satisfy some kind of side relation, and that is why they are constrained in nature.

So, if we are dealing with such constraints some side relations which we need to satisfy while we are optimizing we have the class of optimization problem which is known as constraint optimization problem.

Constrained optimization

- with equality constraints
- with inequality constraints

Simple constr. opt. prob. involving
2 choice var. and 1 const.

$$\max_{x_1, x_2} f(x_1, x_2) \quad \text{s.t.} \quad g(x_1, x_2) = 0$$

Lagrangian: $\mathcal{L} = f(x_1, x_2) + \lambda g(x_1, x_2)$
Lagrange multiplier

Three decision var. x_1, x_2, λ

$$\frac{\partial \mathcal{L}}{\partial x_1} = f_1 + \lambda g_1 = 0 \quad \frac{\partial \mathcal{L}}{\partial x_2} = f_2 + \lambda g_2 = 0 \quad \frac{\partial \mathcal{L}}{\partial \lambda} = g(x_1, x_2) = 0$$

And now we are going to discuss this class of problems. Constrained optimization type problems can be classified in 2 groups. One is with equality constraints and the second one is with inequality constraints.

Now, we are going to discuss the first type which is the optimization problem with equality constraints. And now we are going to learn a technique which is called Lagrangian constrained optimization technique. And this technique is named after an 18th century Italian mathematician named Joseph Louie Lagrange. So, we are going to start with a very simple constrained optimization problem involving 2 choice variables and 1 constant. Needless to say that we can easily generalize this, but let us start with a simple problem to see what is the matter.

So, let us assume we are dealing with a maximization problem. There is a continuous and differentiable function defined over x_1 and x_2 . And we need to maximize this function subject to this constraint. Now, the Lagrangian technique that we are going to study evolves around a function which is known as Lagrangian. And that Lagrangian function is to be defined as follows.

So, here the decision variables will be x_1 and x_2 . And we introduced this new entity or the concept called Lagrange multiplier, which is also unknown. So, in total we have 3 decision variables x_1 , x_2 and λ . Later we will see that this concept Lagrange multiplier has very interesting interpretation both in mathematical terms and also in economics. So, if we need to maximize this Lagrangian function λ , then what to do? We will take first order derivatives of this function with respect to the decision variables that is the way to go. So, we are talking about $\frac{\partial \lambda}{\partial x_1}$ and we get f_1 the first partial derivative of function f of the decision variable x_1 , plus λg_1 , we need to set that equal to 0.

Similarly, we now need to differentiate the Lagrangian function with respect to the second decision variable x_2 . And this will give this partial derivatives f_2 and g_2 . And, as we all know we need to equate this first order condition equal to 0. And do not forget λ . So, that is also you know a decision variable. So, we need to also differentiate the Lagrangian function with respect to this λ . And that will give us the third first order condition. So, we get 3 unknowns in 3 equations. So, of course, this system of equations is solvable.

x_1^*, x_2^*, λ^*
 S.O.C. Matrix of 2nd derivatives of \mathcal{L}

$$\begin{bmatrix} \frac{\partial^2 \mathcal{L}}{\partial \lambda^2} & \frac{\partial^2 \mathcal{L}}{\partial \lambda \partial x_1} & \frac{\partial^2 \mathcal{L}}{\partial \lambda \partial x_2} \\ \frac{\partial^2 \mathcal{L}}{\partial x_1 \partial \lambda} & \frac{\partial^2 \mathcal{L}}{\partial x_1^2} & \frac{\partial^2 \mathcal{L}}{\partial x_1 \partial x_2} \\ \frac{\partial^2 \mathcal{L}}{\partial x_2 \partial \lambda} & \frac{\partial^2 \mathcal{L}}{\partial x_2 \partial x_1} & \frac{\partial^2 \mathcal{L}}{\partial x_2^2} \end{bmatrix} = \begin{bmatrix} 0 & g_1 & g_2 \\ g_1 & \frac{\partial^2 \mathcal{L}}{\partial x_1^2} & \frac{\partial^2 \mathcal{L}}{\partial x_1 \partial x_2} \\ g_2 & \frac{\partial^2 \mathcal{L}}{\partial x_2 \partial x_1} & \frac{\partial^2 \mathcal{L}}{\partial x_2^2} \end{bmatrix}$$

$\begin{bmatrix} \alpha_{11} & \alpha_{12} & g_1 \\ \alpha_{21} & \alpha_{22} & g_2 \\ g_1 & g_2 & 0 \end{bmatrix}$ Bordered Hessian
 $\textcircled{H} \det(H) > 0$

The matrix is also shown as:

$$\begin{bmatrix} 0 & g_1 & g_2 \\ g_1 & \alpha_{11} & \alpha_{12} \\ g_2 & \alpha_{21} & \alpha_{22} \end{bmatrix}$$
 where the α terms are labeled as Hessian elements and the g terms are labeled as Border elements.

Now, after solving we will get the optimized values x_1^* , x_2^* and λ^* . So now, let us consider the second order condition of this maximally constrained maximization problem. So, we know we have to consider a matrix of second derivatives of the function that we are maximizing. In this case, that is this function Lagrangian. So, we construct this particular matrix. So, we first concentrate on the third first order condition, which is basically can be obtained by taking derivative of the Lagrangian function with respect to the Lagrange multiplier.

So, we first focus on that constraint, and then we will differentiate with respect to λ , x_1 and x_2 . Then after, we are done with that, we have to now differentiate the first and the second first order condition with respect to all 3 decision variables. And, that is how we are going to get our components of this matrix. So, this is the matrix that we create from the second derivatives of the Lagrangian function. Now of course, given the Lagrangian function it is easy to derive for certain components and if we do so we get the following.

So, this g_1 and g_2 are the first order partial derivatives of the constraint with respect to the decision variables 1 and 2. Now, we can simplify this further to a form which has easy to deal with notations. This is the matrix that we are going to consider when we are going to discuss our second order conditions. Now note that there is a very interesting stuff going on here. So, this is look at the square matrix here. This is looking more or less

like the Hessian that we have talked about previously. And now there is this border component coming, these border components are coming from the partials of the constraint.

So, this is the border that is generated, and it is bordering this Hessian and that is why it is called bordered Hessian matrix. So, note the difference, in the case of an unconstrained optimization problem we get imple Hessian matrix in the case of a constrained optimization problem we get a bordered Hessian matrix. Now you may ask why the border should be like this. Now, there is an alternative representation possible and if I go for that alternative representation, then bordered Hessian matrix can also be written like this.

So, this is also allowed. Now once these bordered Hessian matrix is constructed, let us see the second order condition how can we state the second order condition. For maximization problem Hessian has to be negative definite matrix subject to the constraint. Thus, if we name this matrix say H then determinant of this H matrix has to be positive and that is the second order condition for maximization.

(Refer Slide Time: 16:29)

What if we generalize to n choice var.?
 $n+1$: F.O.C.
 Bordered Hessian : $(n+1) \times (n+1)$
 Signs of the determinant from left to right $+, -, +, -$ etc.
 $\mathcal{L} = f(x) + \lambda g(x)$ λ^*
 n choice var. & 2 constraints
 $\max f(x_1, x_2, \dots, x_n)$ s.t. $g^1(x_1, \dots, x_n) = c_1$
 $g^2(x_1, \dots, x_n) = c_2$
 $\mathcal{L} = f(x_1, \dots, x_n) + \lambda_1 [c_1 - g^1(x_1, \dots, x_n)]$
 $+ \lambda_2 [c_2 - g^2(x_1, \dots, x_n)]$
 $n+2$: F.O.C.

Now, we have discussed a 2 variable one constraint case. What if we generalize to n choice variables. Then how my first order condition and second order condition are going to change? First order conditions will not change. You know, you have to take the first order partial derivatives set them equal to 0, and you know if there are n number of

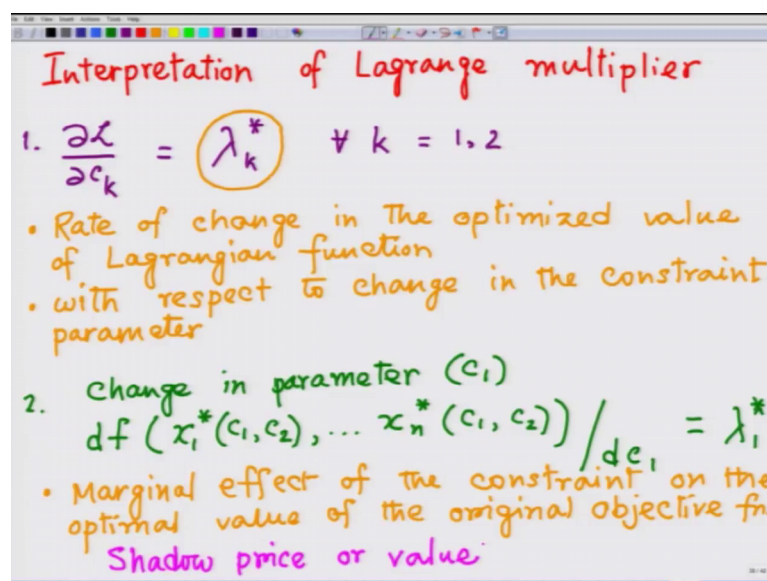

choice variables there will be n number of first order conditions. And of course, you need to differentiate with respect to the Lagrange multiplier λ .

So, if there are n number of choice variables you get $n + 1$ number of first order condition equations. So, in the case of n choice variables and one constraint model, you know the bordered Hessian matrix is going to be $n + 1$ by $n + 1$ matrix. And the signs of the determinants from left to right, we will change in sign we will alternate in sign. And the order should be plus minus plus minus etcetera.

Now, note one thing, we have defined our Lagrangian function as $f(x) + \lambda g(x)$. One may ask what if I replace this plus and you know I replace this plus with a minus. No change, only the sign of the Lagrange multiplier value the optimized value of λ^* we will have a different sign. So, only that much difference will happen if you replace plus with a minus here. Now, let us move on to an extension. And this extensions we will now have n number of choice variables, and 2 constraints.

So, let us write down a fresh maximization problem. Maximize $f(x_1, x_2, \dots, x_n)$ and subject to $g_1(x_1, x_2, \dots, x_n) = c_1$, this is function g_1 . There will be another function g_2 . So, in this case, how can we write the Lagrangian function? Now, the Lagrangian function we will take the following shape. So, of course, as there are n number of decision variables, and there are 2 Lagrange multipliers, there will be $n + 2$ number of decision variables, and you are expecting $n + 2$ number of first order conditions. And you know of course, you know following the way I have shown previously, you can construct the bordered Hessian (Refer Time: 21:56) all. But, now let us concentrate on the interpretation of this λ_1 and λ_2 . What are these variables? So, the issue at hand is to get the interpretation of Lagrange multiplier.

(Refer Slide Time: 22:11)

The image shows a whiteboard with handwritten notes in red, purple, and orange ink. The title 'Interpretation of Lagrange multiplier' is written in red at the top. Below it, there are two main points. Point 1 is written in purple and states that the partial derivative of the Lagrangian function with respect to the constraint parameter c_k is equal to the Lagrange multiplier λ_k^* for $k = 1, 2$. The λ_k^* is circled in orange. Point 2 is written in green and states that the change in the parameter c_1 is equal to the derivative of the optimal value of the original objective function with respect to c_1 , which is λ_1^* . Below point 2, there is a bullet point in orange stating that the Lagrange multiplier is the 'Marginal effect of the constraint on the optimal value of the original objective function' and is also known as 'Shadow price or value'.

Interpretation of Lagrange multiplier

1. $\frac{\partial \mathcal{L}}{\partial c_k} = \lambda_k^* \quad \forall k = 1, 2$
 - Rate of change in the optimized value of Lagrangian function
 - with respect to change in the constraint parameter
2. change in parameter (c_1)
$$\frac{df(x_1^*(c_1, c_2), \dots, x_n^*(c_1, c_2))}{dc_1} = \lambda_1^*$$
 - Marginal effect of the constraint on the optimal value of the original objective function

Shadow price or value

Now, we can approach this interpretation in 2 different way. So, in a general case where you know we are dealing with k number of constraints, we can write and this is the first way of looking at it. And of course, in the case that we were dealing with k takes 2 values, because in we were dealing with 2 constraints. So, this c are the parameters, c_1 and c_2 . So, this Lagrange multiplier is the rate of change in the optimized value of Lagrangian function. And, this is with respect to change in the constraint parameter.

Now, let us look at the second approach to interpret the Lagrange multiplier and for that you know let us remember the discussion that we had earlier that the optimized values of the decision variables in this case x_1^* and x_2^* are functions of the parameters in the model. So, if you change in the parameter value then it will have an impact on the optimized values of the choice variables. That is what we have seen under the heading of comparative statics. Now, we are going to follow that approach to interpret the Lagrange multiplier.

So, suppose we are changing the parameter 1 and that is c_1 . So, we can write Lagrange multiplier value Lagrange multiplier as the following expression. So, this expression is the Lagrange multiplier 1. So, if we follow this line of thought, then this can be interpreted as marginal effect of the constraint on the optimal value of the original objective function. And in economics, this particular interpretation is very popular and this Lagrange multiplier has another name and this is also known as shadow price or

value. Now, we are going to discuss an example of this Lagrangian method. So, this is it for right now. We will continue with these discussion in the next lecture.
