Lecture – 95
Stochastic Regressor

(Refer Slide Time: 00:32)

Hello and welcome back to the lecture on applied econometrics. We have been talking about types of regressor. In the previous lecture, we spoke about non stochastic regressor and we said that that is somewhat unreal. Now, in this lecture we are going to talk about stochastic regressor which is more close to reality. But there is a cost because the moment I talk about reality it is going to be more complex.

And we are going to see the problem or the kind of challenges that we might face when you actually take a stochastic regressor instead of a non stochastic regressor. So, to begin with what is the stochastic regressor? Stochastic regressor is a regressor that the values of the regressor is actually values of X are drawn randomly from a population with finite mean and a finite non-zero variance. Now, what do I mean by this, particularly this non-zero variance?

So, as I said the moment I say the regressor is stochastic that is my all regressors X_i 's that are stochastic, so I essentially allow a sort of randomness into the values of the X . So, I no longer actually determine the values of the X and assign it to the X variables when I run the

regressor. Now, here since I am allowing some amount of randomness if I have a non-zero variance, so if I have a zero variance so that would mean there is no variation in the data.

And that would mean that the component of randomness will go away. So, essentially it has to be a non-zero variance so that is the first thing that we need to remember. Now, when I say that they are stochastic, they are random, so then I will actually allow the regressors to actually vary together. So, there could be a joint probability distribution of the regressors which were actually absent in the previous case.

In the previous case, we assumed all X_i 's are independent to each other and here we are allowing a joint probability distribution of the X_i 's. Now, that is a really relaxation, but at what cost? So, I will talk about that.

(Refer Slide Time: 03:35)

iii) X_i 's may also be related with the error term

$$E(X_i u_i) \neq E(X_i) \cdot E(u_i)$$
$$\neq 0$$

So, the moment actually relax this, what is going to happen is that you can no longer ignore the possibility that the X_i 's are also or rather may also be related with the error term and that is the problem. So, essentially in the previous case we were having when we talked about the unbiasedness of the regression estimator, we were assuming that X_i 's are required to be independent of the error term.

But the moment I allow the joint probability distributions among the X_i variables, I also create the possibility that X_i 's may be related to the error term. And the moment I allow the X_i and the error term to covary, so at that point the bias the condition of base linear unbiased estimator might actually get violated and how is that going to happen let me actually show

you. So, essentially what I am saying here is that I cannot say expectation of let us say some $X_i u_i$, I cannot say it is equal to expectation of X_i and expectation of u_i .

I cannot say this or in other words I cannot say this equal to 0 because if it has to be 0, then the expectation of u_i has to be 0. And even if the expectation of u_i is 0, if this condition does not hold I can never get this value, right. Now as I claim that because of this, because they are not independent, because X_i and error term are covarying the bias is going to exist and how the bias is going to exist.

(Refer Slide Time: 05:33)

$$\begin{aligned}
 \text{Bias} \\
 b_2 &= \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{\sum_{i=1}^n (X_i - \bar{X})^2} \\
 &= \frac{\sum_{i=1}^n (X_i - \bar{X})(\beta_1 + \beta_2 X_i + u_i - \beta_1 - \beta_2 \bar{X} - \bar{u})}{\sum_{i=1}^n (X_i - \bar{X})^2} \\
 &= \beta_2 \frac{\sum_{i=1}^n (X_i - \bar{X})^2}{\sum_{i=1}^n (X_i - \bar{X})^2} + \frac{\sum_{i=1}^n (X_i - \bar{X})(u_i - \bar{u})}{\sum_{i=1}^n (X_i - \bar{X})^2}
 \end{aligned}$$

So, let me actually derive the bias term. How the bias is going to come to play? Now, we know by definition that b_2 which is the estimated regression coefficient is equal to summation $X_i - \bar{X}$ into $Y_i - \bar{Y}$ divided by summation of $X_i - \bar{X}$ where i is equal to let us say 1 to n . And this of course also i equal to 1 to n . Now, if I let us say substitute the values of Y_i , what I will get is and we have actually done previously, $i = 1$ to n $X_i - \bar{X}$.

And here I will have let us say $\beta_1 + \beta_2 X_i$ or $\beta_2 X_i + u_i - \beta_1 - \beta_2 \bar{X} - \bar{u}$. This is something I have done previously and it is of course will be divided by the whole term $i = 1$ to n $X_i - \bar{X}$ whole square; $i = 1$ to n . Now, we know what is going to happen. So β_1 , β_1 is cancelled. I will have a β_2 here, I will have a 2 two here. So, what I am going to do?

I am going to take let us say β_2 out and then I will have summation $i = 1$ to n $X_i - \bar{X}$ and this also going to be $X_i - \bar{X}$. So $X_i - \bar{X}$ whole squared by summation $i = 1$ to n

$X_i - \bar{X}$ whole square. On the other hand, I will have all this u_i and $\bar{u}$ present, so it is going to give me summation $X_i - \bar{X}$ $u_i - \bar{u}$ and that is divided by $X_i - \bar{X}$ whole square, $i = 1$ to n . Now, the first term is going to be 0, this numerator denominator will cancel out. So, I will have beta.

(Refer Slide Time: 07:40)

$$= \beta_2 + \frac{\sum_{i=1}^n (x_i - \bar{x})(u_i - \bar{u})}{\sum_{i=1}^n (x_i - \bar{x})^2} \quad \text{--- (I)}$$

$$\frac{(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2} = a_i \quad \text{--- (II)}$$

$$\sum_{i=1}^n (x_i - \bar{x})(u_i - \bar{u}) = \sum_{i=1}^n (x_i - \bar{x})u_i \quad \text{--- (III)}$$

So, essentially I am going to have $\beta_2 +$ summation of $X_i - \bar{X}$ into $u_i - \bar{u}$ divided by summation of $X_i - \bar{X}$ whole square over all n . Now, I have actually shown previously that this value could be represented as a_i . And if I take $X_i - \bar{X}$ $u_i - \bar{u}$ over all n so then I will have something like I can actually prove this summation $X_i - \bar{X}$ is equal to u_i because $\bar{u}$ is actually constant.

So, basically if you multiply, so then essentially you will have $\bar{u}$ to be you can actually take basically sum of all the errors and that will give you a 0. So, essentially you can represent the numerator as this and let me actually write down the equation number 1, 2 and using 1 and 2 I can actually say; let us say this is 2 and this is 3.

(Refer Slide Time: 08:57)

$$\begin{aligned}
 &= \beta_2 + \sum \underline{a_i u_i} \quad \text{--- (IV)} \\
 E(b_2) &= E(\beta_2) + E(\sum \underline{a_i u_i}) \\
 &= \beta_2 + E(\sum a_i u_i) = a_i E(u_i) \\
 &\text{stochastic} \neq a_i E(u_i) = 0 \\
 &\text{BIAS}
 \end{aligned}$$

So, using 1, 2, 3 I can actually say this is equal to $\beta_2 + \sum a_i u_i$. This is something that I wanted to have. Now, let us say this is equation 4. Now, from my equation 4, if now go back to the previous condition that we have seen if the X_i 's are related to the error term, so if X_i 's are related to the error term what will happen, let me use a different colour, if they are related.

So, if I take an expectation of b_2 here will be expectation of $\beta_2 + \sum a_i u_i$. So, this is going to give you a β_2 , but this one is not going to give you a value of 0. Because a_i and u_i they are correlated, so they are covariant. So as long as they are covariant you cannot write this is equal to let us say a_i into expectation of u_i or something like that, you cannot write that.

So, if you cannot write it, if you could have written that so you could have gotten the value expectation of $u_i = 0$, but you cannot do that now. And because of that you will have a bias term which is actually a problem. And if you have a non-stochastic regressor, so then you do not have any problem. So, this is for the stochastic regressor. But if it was non stochastic, you could have written this is equal to a_i into summation into expectation of u_i and that would have been 0.

And then your bias term would have gone from the basically estimator. So, essentially that is a problem. So, the moment you actually have this X_i related correlate covariant with the error term, you actually have a bias term and the moment you have a bias term your estimator

is no longer going to be a blue estimator, you want a blue estimate. So, it is not going to be a best anymore.

So, that is a problem and we sort of need to actually take care of that and that is why whenever we actually deal with stochastic regressor, we make another assumption that is in addition to the other assumptions that we make for estimating regression.

(Refer Slide Time: 11:30)

Handwritten notes on a blackboard:

- iii) X_i and u_i 's are required to be independent
- $E(u_i | X_i) = 0$
- $Cov(X_i, u_i) = 0$
- $E(u_i) = 0$

So the assumption that we are going to make is that you need to have X_i and u_i 's are required to be independent. And you write it expected value of u_i given all $X_i = 0$, so mean value of the error term given all $X_i = 0$, so that is what you assume. So, if your assumption is correct, if you can actually make this assumption, then your stochastic regressor will behave in a way your non stochastic regressor actually behaves.

And that is why whenever you are dealing with stochastic regressor, you need to make this extra assumption that we have just derived. And when you do that what you will have is you will actually have covariance of $X_i, u_i = 0$ or also you can say expectation of $u_i = 0$ so which are basically you need to have for your regression equation. So, with this, we will end the lecture on stochastic regressor.

And in the next lecture, we are actually going to talk about the assumptions that we have been dealing with from for all the past lectures in the second module. So, all of those exercises that you have done will culminate to some assumptions and we will talk about all assumptions in

one go. So, we will deal with the stochastic regressor and non-stochastic regressor and their corresponding assumptions in the next couple of lectures. Thank you.
