Diffusion Equation Path Integral (2), Autocorrelators

Right, welcome back.

(Refer Slide Time: 00:38)

Recall : $\Delta = \lim_{n \rightarrow \infty} \left\langle \exp \left(\frac{t}{n} \sum_{k=1}^n U \left(x + \sqrt{\frac{t}{n}} \sum_{j=k}^n y_{j+1} \right) \right) \right\rangle$
 $\times \exp \left(\sqrt{\frac{t}{n}} \sum_{k=1}^n y_k \frac{\partial}{\partial x} \right)$

with $y_{n+1} = 0$. In the limit $n \rightarrow \infty$, $\langle y_j \rangle = 0$, $\langle y_j^2 \rangle = D$.

Thus, by the CLT, $\sum_{k=1}^n y_k \xrightarrow{\text{distribution } (n \rightarrow \infty)} N(0, nD)$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 3

Now, by making use of the property of the translation generator the first derivative in the exponential, we were able to simplify the expression of the propagator and bring all the derivative terms to the right and all the non-derivative terms to the left. This was a very important simplification that we could achieve because of this particular property.

And then we had this important relations that in the limit that n tends to infinity which we ultimately have to do I have to take in the limit n tends to infinity each of these y j's is normally distributed with a mean of 0; and a variance of D, variance of D each of the each of these y j's. And by using the central limit theorem we find that the summation of these y j's up to n are normally distributed with a mean of 0, and a variance of n D, so that is where we concluded the last lecture last class. Let us continue from there.

(Refer Slide Time: 01:37)

Defining a Brownian motion by $W_k = \sqrt{\frac{t}{n}} \sum_{j=1}^k y_j$ with

$$\langle W_k \rangle = 0; \langle W_k^2 \rangle = \frac{t}{n} kD = \frac{kt}{n} D, dW = W_k - W_{k-1} = \sqrt{\frac{t}{n}} y_k;$$

$$\langle dW \rangle = 0; \langle (dW)^2 \rangle = \left\langle \left(\sqrt{\frac{t}{n}} y_k \right)^2 \right\rangle = \frac{t}{n} D = Ddt$$

IT KOOBEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, we define a Brownian motion? How do we define it? As you recall Brownian motion is the sum of random variables, and each of those random variables are normally as I am sorry the random variables are such that the Brownian motion becomes a sum of those random variables. And at any particular point in time, the random the aggregate of all those random,

the sequence of those random variables is normally distributed due to the central limit theorem as a mean of 0, and a variance equal to the length of evolution.

So, we define a Brownian motion by W_k is equal to $\sqrt{t/n}$ times the summation of y_j with j equal to 1 to k . Please note these subscripts the indices we have W_k is a summation of random variables y_1, y_2, y_3 from 1 to k .

Let us look at the properties of this Brownian motion to ensure that it is a Brownian motion. We have the expectation value of W_k is clearly 0, because the expectation value of each y_j is 0. The expectation value of W_k^2 now that is interesting, recall that the expectation value of each y_j is equal to D .

Therefore, when you are multiplying by $\sqrt{t/n}$ the you are scaling the variable by $\sqrt{t/n}$, the variance gets scaled by t/n , so the variance will be equal to t/n , and since there are n y_j 's here. So, we have t/n into D to reiterate to repeat each y_j has a variance of D . There are k of them, so the total variance becomes kD and each of them are independent of the other. So, the total variance becomes kD . And we are scaling each y_j by $\sqrt{t/n}$, so the variance gets scaled by t/n . So, we have t/n into kD .

And dW the increment $W_k - W_{k-1}$ is nothing but $\sqrt{t/n} y_k$. And clearly the expectation of dW is 0, because the expectation of y_k is 0; and the expectation of dW^2 is equal to t/n into this expression this particular expression expectation of y_k^2 . Remember the expectation of y_k^2 was D , therefore, it becomes t/n into D , and that is nothing but the D into the step size that is $D dt$.

(Refer Slide Time: 04:46)

$$\begin{aligned}
 F / A: \Delta &= \lim_{n \rightarrow \infty} \prod_{j=1}^n \left\langle \exp\left(\frac{t}{n} U\right) \exp\left(\sqrt{\frac{t}{n}} y_j \frac{\partial}{\partial x}\right) \right\rangle \\
 &= \lim_{n \rightarrow \infty} \left\langle \exp\left(\frac{t}{n} \sum_{k=1}^n U\left(x + \sqrt{\frac{t}{n}} \sum_{j=k}^n y_{j+1}\right)\right) \exp\left(\sqrt{\frac{t}{n}} \sum_{k=1}^n y_k \frac{\partial}{\partial x}\right) \right\rangle \\
 \Delta &= \lim_{n \rightarrow \infty} \left\langle \exp\left(\frac{t}{n} \sum_{k=1}^n U\left(x + W_k - W_n\right)\right) \exp\left(-W_n \frac{\partial}{\partial x}\right) \right\rangle
 \end{aligned}$$

This is the operator form of the propagator.

So, let us now what do we have? We started with this first expression for delta, we simplified it by translation generator property, and we got all the derivatives to the right, we got all the other terms to the left, and then we introduced the concept of Brownian motion.

By introducing the concept of Brownian motion to represent the sum of divisors, we simplify the summation the terms; within the summation and we write them as a Brownian motions it is quite straightforward. We write summation of y_k as W_k , and we write summation of y_j plus 1 from j equal to k to n as a difference of two Brownian motions from j equal to 1 to n and then from j equal to 1 to k .

So, j equal to 1 to n minus j equal to 1 to k . In other words, it is equal to y_n minus y_k , but there is a minus sign here in defining the Brownian motion and therefore it becomes y_k minus

y n. So, this is the operator form of the propagator. The y operator form because it contains the derivative operator to the extreme right.

(Refer Slide Time: 06:01)

To obtain the expression for the kernel i.e. of $K(x,t;y)$ that satisfies $\psi(x,t) = \int d\theta K(x,t;\theta)\psi(\theta,0)$ we have

$$\begin{aligned} \psi(x,t) &= (\Delta \psi)(x,0) \\ &= \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(x + W_k - W_n) \right] \exp \left(-W_n \frac{\partial}{\partial x} \right) \psi(x,0) \right\rangle \\ &= \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(x + W_k - W_n) \right] \psi(x - W_n, 0) \right\rangle \quad (\text{Set } \theta = x - W_n) \\ &= \int d\theta \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(\theta + W_k) \right] \delta(x - W_n - \theta) \right\rangle \psi(\theta, 0); \end{aligned}$$

IT FOOTER NPTEL ONLINE CERTIFICATION COURSE 6

Now, we move on to find the expression for the kernel. The kernel has to satisfy this equation which is given at the top in the green box $\psi(x,t) = \int d\theta K(x,t;\theta)\psi(\theta,0)$ subject to $\theta = x - W_n$.

In other words, it transform the state $\psi(\theta,0)$ to the state $\psi(x,t)$. It transform the state $\psi(\theta,0)$ to the state $\psi(x,t)$. Recall that the propagator transform the state $\psi(\theta,0)$ to this state $\psi(x,t)$. Here we have the kernel doing a slightly different job. It is transforming the state $\psi(\theta,0)$ to the state $\psi(x,t)$.

Now, as I mentioned the propagator and did the job of transforming the state x_0 to the state x_t , or the state at x_0 to the state at x_t , this is transforming the state at θ_0 to the state at x_t . How to work it out? Let us start with the continue with the expression for the propagator. And let us operate that on $\psi(x_0)$, we get this expression with the d by $d x$ operating on $\psi(x_0)$. We make a simplification.

We now again we use this translation property of exponential $\frac{d}{dx}$ exponential the second term exponential minus $W_n \frac{d}{dx}$ operating on $\psi(x_0)$ does a translation in spatial coordinates and it gives you $\psi(x - W_n, 0)$.

The this because it is a derivative with respect to the spatial coordinate, it does a translation with respect to the spatial coordinates, and it shifts ψ from x_0 to ψ at $x - W_n, 0$; 0 is the time coordinate. So, it does not affect the time coordinate, it does not because there is no time coordinate involved in the derivative. So, it only the spatial coordinate is there.

And the spatial derivative operates on the spatial coordinates, and it gives you ψ of $x - W_n, 0$. So, this expression gives me the expression in this blue box due to the translation generation property of the exponential of the derivative.

Now, what I do is, I said θ equal to $x - W_n$. To simplify further recall I have to bring this in the form $\theta, 0 \psi(\theta, 0)$. So, what I do is, I substitute θ equal to $x - W_n$.

When I substitute ψ , when I substitute $x - W_n - \theta$ to introduce this constraint into this expression, I use a direct delta function, I introduce this direct delta function within the integration and I write the integration together with $\delta(x - W_n - \theta)$ that is precisely $x - W_n - \theta$ is precisely representing this particular change in coordinates. We are shifting $x - W_n$ or we are changing $x - W_n$ as θ substituting $x - W_n$ as θ .

And in order to implement that substitution, I introduce a delta function $x - W_n - \theta$. So, that this integral operates now only over the expressions where this θ equal to $x - W_n$ holds. The rest is simplified $x - W_n$ is written as θ . So, it becomes $U(\theta + W_n)$. And now ψ which was written as $\psi(x - W_n, 0)$ now becomes $\psi(\theta, 0)$. And we have the expression for the kernel.

(Refer Slide Time: 10:34)

F/A:

$$\psi(x, t) = \int d\theta \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(\theta + W_k) \right] \delta(x - W_n - \theta) \right\rangle \psi(\theta, 0)$$

Also, by definition $\psi(x, t) = \int d\theta K(x, t; \theta) \psi(\theta, 0)$. Hence

$$K(x, t; \theta) = \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(\theta + W_k) \right] \delta(x - W_n - \theta) \right\rangle$$

IT KOOBEE | NPTEL ONLINE CERTIFICATION COURSE 7

And the kernel is now in can be written or is in the form of this expression the last red box that we have K of x, t, θ is equal to limit n tending to infinity this whole expression together with this and delta function, together with this delta function including this delta function. And that is clearly seen by comparing these two equations and comparing the expression for the K in this expression and this integrand.

(Refer Slide Time: 11:10)

$$\psi(x,t) = (\Delta\psi)(x,0) : \Delta \text{ is the propagator}$$
$$\Delta = \lim_{n \rightarrow \infty} \left\langle \exp\left(-\frac{t}{n} \sum_{k=1}^n U(x+W_k - W_n)\right) \exp\left(-W_n \frac{\partial}{\partial x}\right) \right\rangle$$
$$\psi(x,t) = \int dy K(x,t;y) \psi(y,0) ; K(x,t;y) \text{ is kernel}$$
$$K(x,t;y) = \lim_{n \rightarrow \infty} \left\langle \exp\left[-\frac{t}{n} \sum_{k=1}^n U(y+W_k)\right] \delta(x - W_n - y) \right\rangle$$

Now, one more step of simplification can be achieved. This is the relative expressions for the propagator and the kernel. The upper expression within the red box is that for the propagator that we had earlier; and the lower expression is for the kernel. And important thing is that in the propagator we have this first derivative the translation generator and in the second the kernel that translation generator is replaced by the delta function.

(Refer Slide Time: 11:43)

$$F/A: K(x, t; y) = \lim_{n \rightarrow \infty} \left\langle \exp \left[\frac{t}{n} \sum_{k=1}^n U(y + W_k) \right] \delta(x - W_n - y) \right\rangle$$

In the continuum limit of BM, we can assume $W(s)$ as a BM path initiating at y i.e. $W(0) = y$ at $s = 0$;

$W(t) = (y + W_n)$ at $s = t = n \cdot \frac{t}{n}$, and

$W(s) = (y + W_k)$ for arbitrary $s = k \cdot \frac{t}{n}$.

Then, $K(x, t; y) = \left\langle \exp \left[\int_0^t U(W(s)) ds \right] \delta(x - W(t)) \right\rangle$

Now, we do a little bit more of simplification. What we do is, we define a Brownian motion again, we define a Brownian motion by the expression that if the Brownian path starts at y at t equal to 0, therefore, W of 0 is equal to y . We define a Brownian motion that way W is 0 is equal to y it starts at the path Brownian path starts at y . So, we have W 0 equal to y at s equal to 0; s is now the new time coordinate representing the time coordinates.

So, at s equal to 0, we have W 0 equal to y and at s equal to t that is the conclusion of the path, the terminal point of the path. We have W of t small t that is W of small t is equal to y plus W_n , y plus W_n that is at s equal to t that represents. And at any intermediate path we can represent for any intermediate value of s , what do we have we have W s is equal to y plus W_k . Where.

How do we define k or what is the relation between k and s ? s is equal to k under root t upon n . k is, recall k is the number of steps right time steps and each step is of length t by n . So, the t in terms of continuous time it works out to k into t upon n which is the arbitrary or the general value of s lying between 0 and small t .

Making these substitutions, I can write this summation as an integral. Now, assuming that this W that we have defined now is continuous Brownian motion, I can make this substitution replace this summation by the integral $\int_0^t W_s$, integrated within the limit 0 to t , so this gives, and the rest is this quite simple.

The delta function now operates because it is $W_n - y$ $x - W_n - y$, it becomes $x - W_t$. Recall what is W_t ? W_t is equal to $y + W_n$. So, substituting $y + W_n$ is equal to W_t , we get this expression the delta function, and the rest is mere substitution. So, we are now able to write we are now able to write the expression for the kernel in terms of a continuous Brownian motion an integral of a function of a Brownian motion rather than summation of a discrete sum of random variables.

(Refer Slide Time: 14:50)

$$\begin{aligned} \text{Then, } K(x, t; y) &= \left\langle \exp \left[\int_0^t U(W(s)) ds \right] \delta(x - W(t)) \right\rangle \\ &= E_t \left\{ \exp \left[\int_0^t U(W(s)) ds \right] \delta(x - W(t)) \right\} \\ &= E_{.xt} \left(\exp \left(\int_0^t U(W(s)) ds \right) \right) \text{ where } E_{.xt}(\zeta) = E_t(\zeta \delta(x - W(t))) \end{aligned}$$

10

So, now the important thing, what have we got, we have got the kernel as the expectation value of a certain quantity. We expectation value of the exponential of an integral, now when we have the expectation value, obviously, it will be integrated, it will involve a probability density function because, or a probability mass function either way. And then it has to be summed over or integrated over as the case may be with respect to this expression of random variables.

So, the basic point that I want to emphasize is that here we are having to talking about the continuous case, we have having a probability density function, and then we are having this random variable here. We are integrating the expression in order to arrive at the expected value.

And we have to do this integration over the various possible realizations, various possible realizations of this random variable. And because this random variable is continuous, there is an integration here. What do we find it is an integration over all possible paths, and therefore it is called a path integral right. So, we have arrived at this expression. Recall this is the origin of this path integral can be traced back to the diffusion equation. Therefore, this represents an explicit solution of the diffusion equation.

(Refer Slide Time: 16:28)

AUTOCORRELATION FUNCTIONS

- It is the primary measure of the degree of `memory` possessed by the random variable as it evolves in time.
- The following expressions are valid for all stationary discrete stochastic processes, and not just Markov processes.

IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE 11

Now, some definitions before we proceed further, the concept of autocorrelation functions. As I mentioned several times, a stochastic process involves a sequence of random variables. Random variable at t equal 1, random variable representing the process at t equal to 2, random variable representing the process at t equal to 3 and so on a sequence of random variable which is usually indexed with respect to time.

Now, the correlation between these random variables at different points in time is conveys very important information about the dynamics of the process about the memory of the process. And therefore, it is a very important parameter as far as various stochastic processes are concerned. It is defined as the correlation function.

(Refer Slide Time: 17:30)

We have $E[X(t_1)X(t_2)] = \sum_j \sum_k x_j x_k P_2(k, t_2; j, t_1)$
 $= \sum_j \sum_k x_j x_k P_2(k, t_2 | j, t_1) P_1(j, t_1)$
 For a stationary random process, on writing $t_2 - t_1 = t$
 $C_X(t) = E[X(0)X(t)] = \sum_j \sum_k x_j x_k P(k, t | j) P(j)$

This is the autocorrelation function $C_X(t)$ of the stationary, discrete random process $X(t)$, in the case when the mean value is zero at all times.

12

Precisely, we have the expectation the correlation function is defined as the expectation of X at t_1 , and X at t_2 . The expectation of this value, you see you will have various realizations of t_1 at t_1 . And you will have various realizations of x at t_2 . Work out the correlation between them, and that is precisely what gives you an indication of how the process is moving forward in time.

And this is as you can see on the right hand side, this represents the summation in the case of discrete processes, it represents the summation over j and k of all possible realizations of the

of the stochastic process at t equal to 1, at t equal to 2 together with the joint probability together with the two time joint probability of the process being in state j at time t_1 , and the process being in state k at time t_2 that is what is called the correlation function.

Now, this probability point issue can be simplified further. And we by using Baye's theorem, we can express it at a two time conditional probability. And a onetime probability for a stationary process; it gets simplified further because time translation does not change the properties of the system.

Therefore, we can write $t \times E$ of X_t, X_{t_1}, X_{t_2} as equal to E of $X_0 X_t$, and the rest of the properties also get simplified the conditional probability also gets simplified. It becomes and then this probability the one time probability also gets simplified, you can use the probability at t equal to 0 for that matter. And from t equal to 0, you can have the conditional probability that this system moves to the state k at time t , and work out the conditional work out the correlation function auto correlation function.

And that in that way with respect to t equal to 0 you can work out the auto correlation function. At any other point in time, it would be representative of other auto correlation functions also provided the system is a stationary random process, a stationary stochastic process that is time translation does not influence the system.

(Refer Slide Time: 20:17)

When the mean value of a stationary random process is non-zero, the autocorrelation function is defined in terms of the deviation from the mean value, namely $\delta X = X - E(X)$. In this case:

$$C_X(t) = E[\delta X(0)\delta X(t)]$$
$$= \sum_j \sum_k x_j x_k P(k,t|j)P(j) - [E(X)]^2$$
$$E(X) = \sum_j x_j P(j)$$

 13

Now, this is the case where the definition that I have given above is the situation when the mean value of the random process is non zero. If the mean value of the process is 0, then the above formula operate. If the mean value of the processes is not 0, then we measure correlations in respect of deviation from the mean.

We define deviation from the mean as delta of X is equal to X minus the mean of X, then delta X is equal to X minus mean of X that is the standard formula for deviations. And we work out the correlation as the expected value of delta X 0 delta X t. The correlation between these two and the formula change slightly this additional term in the green box comes into play.

(Refer Slide Time: 21:09)

MARKOV PROCESS: AUTOCORRELATION`

- In the case of a Markov process, however, a knowledge of the autocorrelation function is of particular significance.
- This is because the autocorrelation function depends on the conditional probability, ◦
- The conditional probability determines all the joint probabilities associated with a Markov process.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

For Markov processes, the autocorrelation becomes all the more important. Recall what are Markov processes? Markov processes are those processes where the process has limited memory the memory is confined to the immediately preceding state. So, in the case of Markov processes, the autocorrelation function has special significance because the auto correlation function depends on the conditional probability, and the conditional probabilities determine all the joint probabilities in the case of Markov processes.

And the joint probabilities are what we want ultimately, because our path probability is a sequence of joint probabilities. So, knowing the joint probabilities, we can calculate path probabilities, and joint probabilities are determined by conditional probabilities in the case of Markov processes.

(Refer Slide Time: 22:04)

AUTOCORRELATION

- We have:
- $E[X(t')X(t)] = \int dx' \int dx xx' p_2(x, t; x', t')$
- $= \int dx' \int dx xx' p_2(x, t|x', t') p_1(x', t')$
- For a stationary process, setting $t'=0$,
- $E[X(0)X(t)] = \int dx' \int dx xx' p(x, t|x') p(x')$
- This is the autocorrelation $C_x(t)$ when $E[X(t)] = 0$.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 15

For continuous stochastic processes, these are the formula a slightly different from what we have for the discrete expression, only basic difference is that we replace the summation by integration, and the probability functions by probability density functions, the rest is more or less absolutely parallel right.

(Refer Slide Time: 22:26)

- When the mean value of the random process is not zero i.e. $E[X(t)] \neq 0$, then we have $C_X(t) = E[\delta X(0)\delta X(t)] = \int dx' \int dx x x' p_2(x, t; x', t') - [E(X)]^2$ where $\delta X = X - E(X)$ and $E(X) = \int dx x p(x)$

(Refer Slide Time: 22:26)

The slide features a dark blue header bar at the top. The main content area is white with the text "LANGEVIN EQUATION" centered in a bold, black, sans-serif font. A small blue circle is positioned to the right of the text. At the bottom, there is a dark blue footer bar containing the IIT Roorkee logo on the left, the NPTEL Online Certification Course logo in the center, and the number "17" on the right.

(Refer Slide Time: 22:27)

LANGEVIN EQUATION

- Consider the dynamics of a Brownian particle.
- Let mass of the particle be unity.
- The dynamical equation is:
- $\dot{V} = -\gamma V + L(t)$
- The right-hand side is the force exerted by the molecules of the surrounding fluid.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

Now, I have talked about the diffusion equation in a lot of detail. You would recall I when I started with deriving the diffusion equation. What do you do what we did was we talked about the random motion of a particle in a fluid, we had certain predefined probabilities of these particle moving to the left moving to the right in an infinite decimal time; and on that basis we arrived at the diffusion equation.

We did not, we did not explicitly encounter the Newtonian force equation we did not present the dynamics of the particle in the form of a Newtonian force equation and then try to solve it. We had a slightly obscure approach to the study of the dynamics. We studied the dynamics purely in the context of probabilities. We did not talk about the dynamics per say as a Newtonian framework as a dynamical framework where the laws of motion manifest themselves explicitly.

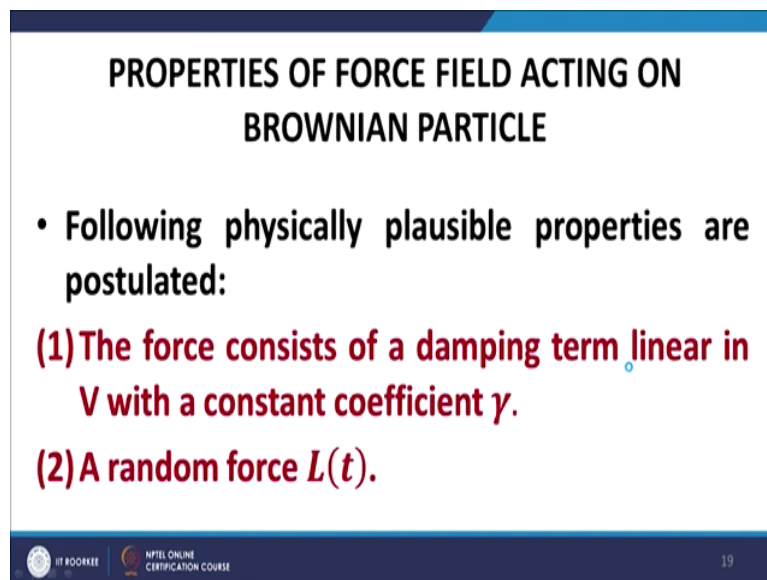

Recall now the Langevin equation does just that. It gives you or it presents the dynamics of the system which is subjected to some kind of a stochastic force field, and as explicitly presenting it in the Newtonian framework, and that is what I want to take up now.

We are talking about the dynamics of the Brownian particle. Recall that a Brownian particle is a microscopic particle which is immersed in a fluid, and which executes random motion due to the collisions that it encounters with the various molecules of the fluid.

Let us assume for simplicity the mass is assumed to be unity in any case we can rescale other quantities if we so desire and make the mass unity. So, that is not an issue really and that does not affect the generalization of the exposition. Now, we can write the assuming that the mass to be unity, the force equation, recall that we are working in non relativistic dynamics in Newtonian dynamics.

In Newtonian dynamics, we can write the equation of motion as the acceleration that is the rate of change of velocity is equal to minus gamma V is the velocity plus L t. The in the terms I will explain in a minute, but this is what is the Newton's equation of motion for the Brownian particle which is encountering collisions from various sides randomly by other particles of the fluid.

(Refer Slide Time: 25:37)

PROPERTIES OF FORCE FIELD ACTING ON BROWNIAN PARTICLE

- Following physically plausible properties are postulated:
 - (1) The force consists of a damping term linear in V with a constant coefficient γ .
 - (2) A random force $L(t)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 19

Now, what is the property of the force that we are talking about in the current context? Number 1, there be one in this particular equation in fact we have introduced a damping term as well, the first term this first term minus γV is a damping term and it operates linearly in velocity.

And in the absence of any force it will cause the dissipation of energy, and result in the absence of any $L(t)$ that is any external force the particle will gradually come to rest due to the damping term. So, we have one damping term which is a γ is a constant quantity, and it is linear in the velocity. And then we have a stochastic term which is $L(t)$.

(Refer Slide Time: 26:36)

STATISTICAL PROPERTIES OF $L(t)$

- This $L(t)$ is **RANDOM** i.e. comprises of impulses at random time intervals.
- However, its averaged properties over an ensemble of similar systems:
 - $\langle L(t) \rangle = 0$
 - $\langle L(t)L(t') \rangle = \Gamma \delta(t - t')$ where Γ is a constant.
 - Properties of $L(t)$ are independent of V , so that $L(t)$ acts as an external force.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 20

Let us look at the properties of $L(t)$. The $L(t)$ is a random force; random in the sense that it is an impulse which takes place at random intervals of time. The force is the manifestation of collisions between the various fluid molecules and the Brownian particle. So, let us explore the physical characteristics of this particular force before I talk about the statistical properties.

(Refer Slide Time: 27:11)

PHYSICAL JUSTIFICATION OF PROPERTIES OF $L(t)$

- The force $L(t)$ is caused by the collisions of the individual molecules of the surrounding fluid with the particle.
- Each collision is practically instantaneous.
- Successive collisions are uncorrelated.
- The collision force varies rapidly.
- Thus, its autocorrelation function is postulated as:
- $\langle L(t)L(t') \rangle = \Gamma \delta(t - t')$ where Γ is a constant.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 21

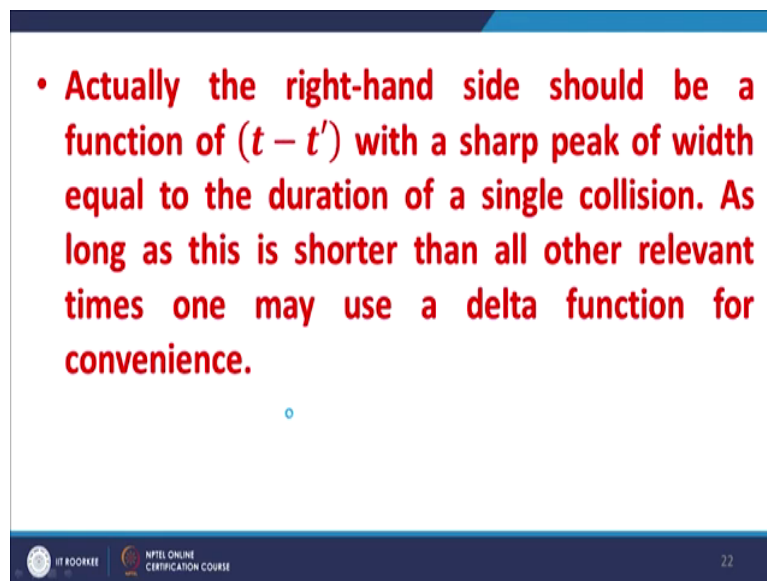

Now, the first thing is that each the collision the time of collision is a very small. As a result of which the collisions may be assumed to be instantaneous. And then the collisions from one particle due to one particle the impact of the collision due to one particle and the impact of the collision due to another particle are mutually independent. They do not influence each other. And thirdly the force with which they collide with each other that force is not constant that is also varying rapid varies rapidly.

Now, the keeping in view these three properties, keeping in view the first property, collisions are spontaneous, collisions are uncorrelated with a between each other. And the collision force varies rapidly. We are able to model it in as a or together with a delta function, and that gives us the following two properties of the random force or the external force.

Number 1 is on the average $L(t)$ will be equal to 0, and number 2 the correlation or the autocorrelation of $L(t)$ at different points in time is delta is a delta function or is a modified delta function with gamma capital gamma here representing the strength of the force. And $L(t)$, $L(t)$ dash is the auto correlation expected value of $L(t)$ $L(t)$ dash is the autocorrelation.

So, the autocorrelation of the random force that is exerted on the Brownian particle due to collision between various molecules is in a sense delta correlated with an additional term that represents the magnitude of the that a scaling term. This is nothing but a scaling term which represents the magnitude of the force by which they are impacted right.

(Refer Slide Time: 29:19)

- **Actually the right-hand side should be a function of $(t - t')$ with a sharp peak of width equal to the duration of a single collision. As long as this is shorter than all other relevant times one may use a delta function for convenience.**

Now, the by talking about this we have taken a certain approximation and a very strong approximation. The approximation is that the time span in which the effect of the force acts on the impulse of the force acts on the Brownian particle due to the collision is very very small. It

is in it is much smaller than other time scales that are relevant to this particular problem. And as a result of which not much approximation is introduced by the in use of delta function to model this collision in colliding force.

Now, we have talked about average force being average of $L(t)$ being 0 or the average of the external force being 0, we have talked about autocorrelation, so there must be the issue of ensemble error. Now, when we talk about ensemble the assembled ensemble in this particular situation can consist of many many particles, at the same time they which are observed and the properties assessed many particles being observed and their properties determined in the same field.

Or the as same of single particle may be tracked over a sustained period of time in such a way that or to such an extent or to such a length to such a length that the time span is large enough for the impact of one collision, and not to impact the or not to influence the impact of the other collision. This is the fundamental condition that has to be met when we talk about the ensemble on the basis of which the averages or the statistical properties that I have mentioned earlier that is these two properties.

Property 1 and property 2, these two properties that I have mentioned these two properties must be calculated very carefully with respect to ensembles which satisfy either of these two conditions.

Either we have many particles in the same force field and they are assessed at the same point in time, or we have a single particle being tracked at different points in time with the points in time being so far apart that the influence of one collision does not carry over to the other collision. And even in the first case the particles that are studied together at the same time must be distant enough such that they do not get influenced by each other.

So, the Langevin equation is a special case of the general stochastic differential equation. My next program is to take up a detailed solution of the Langevin equation where again we will encounter the path integral.

And then will also establish a similarity between the Langevin equation which represents the pure dynamics of the system which represents which is explicitly showing you the Newtonian dynamics, the laws of motion governing the system, and the Fokker-Planck equation which represents the probabilities of this is of the conditional probabilities of various issues involved in the dynamics of the system. So, that is what I have in the agenda.

Thank you.
