Lecture - 18
Langevin & Fokker Planck Equation: CLT Example

Welcome back. So, before the break I explained how to get the solution or the path integral solution for the Langevin equation. Let us explore the Langevin equation further.

(Refer Slide Time: 00:38)

Let us try to look at the existence of a relationship between the Langevin equation and the Fokker Planck equation. Langevin equation is a dynamical equation. It relates to the explicit in a sense the Newtonian dynamics of this of the stochastic system. The Fokker Planck equation on the other hand is a probabilistic equation.

Now, let us see how we can arrive at or what if there is and if there is, then what is the relationship between the Langevin equation and the Fokker Planck equation.

(Refer Slide Time: 01:08)

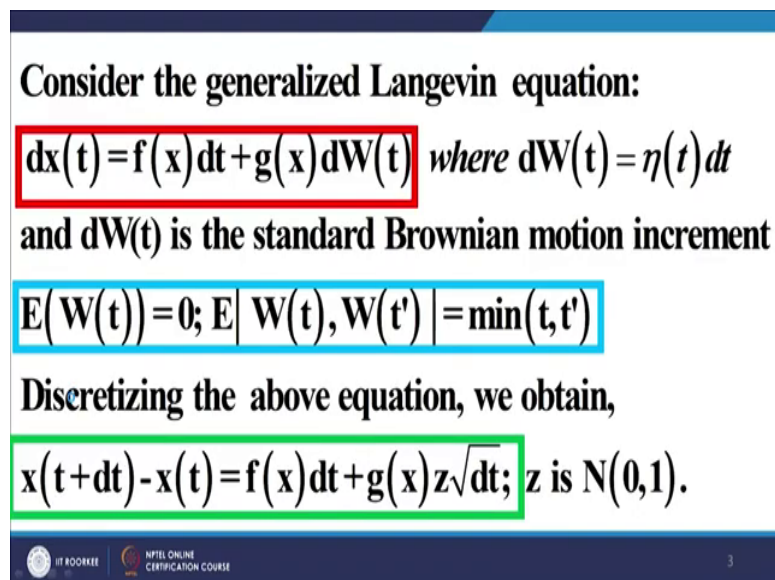

Consider the generalized Langevin equation:

$$dx(t) = f(x)dt + g(x)dW(t) \text{ where } dW(t) = \eta(t)dt$$

and $dW(t)$ is the standard Brownian motion increment

$$E(W(t)) = 0; E|W(t), W(t')| = \min(t, t')$$

Discretizing the above equation, we obtain,

$$x(t+dt) - x(t) = f(x)dt + g(x)z\sqrt{dt}; z \text{ is } N(0,1).$$

The slide content includes the following elements:

- A title: "Consider the generalized Langevin equation:"
- A red-bordered equation: $dx(t) = f(x)dt + g(x)dW(t)$ with the text "where $dW(t) = \eta(t)dt$ " to its right.
- A text line: "and $dW(t)$ is the standard Brownian motion increment".
- A blue-bordered equation: $E(W(t)) = 0; E|W(t), W(t')| = \min(t, t')$.
- A text line: "Discretizing the above equation, we obtain,".
- A green-bordered equation: $x(t+dt) - x(t) = f(x)dt + g(x)z\sqrt{dt}; z \text{ is } N(0,1).$
- At the bottom, there are logos for IIT Roorkee and NPTEL Online Certification Course, and a page number "3".

We start with the Langevin equation in the form that is given in the red box here $dx(t)$ is equal to $f(x)dt$ plus $g(x)dW(t)$.

$dW(t)$ is as usual the infinitesimal Brownian motion increment which can also be written in terms of the white noise in the form given in the right hand corner. Here $dW(t)$ is equal to $\eta(t)dt$ where $\eta(t)$ is white noise and $W(t)$ has the following properties fundamental properties defining properties in some sense. $E(W(t))$ is equal to 0 and the expected value of the expected values of the $W(t)$ at different points in time is equal to minimum t, t' dash.

The first step is to discretize the above equation. In fact, this is the familiar process that we follow when we start working with the Langevin equation. We discretize the equation. Discretizing the equation leads us to the expression that is given in the green box right at the bottom of the slide $x(t) + dt$ minus $x(t)$ that is $dx(t)$ here on the left hand side and gives us $f(x)dt$ plus $G(x)$ and $dW(t)$ can now be written as $z\sqrt{dt}$, where z is the standard normal variate standard Gaussian variate if you like under root dt .

(Refer Slide Time: 02:33)

For arbitrary $G(x(t))$

$$\frac{\partial}{\partial t} G(x(t)) = \lim_{dt \rightarrow 0} \frac{G[x(t+dt)] - G[x(t)]}{dt}$$

$$= \lim_{dt \rightarrow 0} \frac{G[x(t) + dx(t)] - G[x(t)]}{dt} \quad \boxed{x(t+dt) = x(t) + dx(t)}$$

But $dx(t) = f(x)dt + g(x)z\sqrt{dt}$

$$\frac{\partial}{\partial t} G(x(t)) = \lim_{dt \rightarrow 0} \frac{G(x(t) + f(x)dt + g(x)z\sqrt{dt}) - G(x(t))}{dt}$$

IT KOOKEE NPTEL ONLINE CERTIFICATION COURSE 4

And for arbitrary for any arbitrary function $G(x)$ of t we can write d of t of $G(x)$ of t as limit dt tending to 0 $G(x(t) + dt)$ minus $G(x(t))$.

This can be simplified and be can be written in the form by using the expression $x(t) + dt$ is equal to $x(t) + dx(t)$ expanding as $t + dt$ around $x(t)$. We can write to first order $x(t) + dt$ is

equal to $x + dt$ plus dx that is precisely what we write here $G(x + dt)$ minus $G(x)$ upon dt and the limit dt tending to 0.

But dx recall dx that appears here is nothing from the previous equation; dx is equal to $f(x)dt + g(x)z\sqrt{dt}$ this is from the previous equation. You can see it here. It is here in the red box here and also together with the expression in the green box here. The left hand side is nothing, but dx , so dx is equal to $f(x)dt + g(x)z\sqrt{dt}$, right.

So, we use that expression and we substitute it in our expression for d by $dt G(x)$ and what we get is $G(x + dx)$ plus dx is substituted by the expression in the blue box. So, we get $f(x)dt + g(x)z\sqrt{dt}$ plus $G(x + f(x)dt + g(x)z\sqrt{dt})$ minus $G(x)$ upon dt and with the limit dt tending to 0.

(Refer Slide Time: 04:21)

$$F / A: \frac{\partial}{\partial t} G(x(t)) \quad \theta(x + dx) - \theta(x) = \theta'(x)dx + ..$$

$$= \lim_{dt \rightarrow 0} \frac{G[x(t) + f(x)dt + g(x)z\sqrt{dt}] - G[x(t)]}{dt}$$

On Taylor expanding the first term *around* $x(t)$

$$= \lim_{dt \rightarrow 0} \frac{1}{dt} \left\{ G'(x) [f(x)dt + g(x)z\sqrt{dt}] + \frac{G''(x)}{2} [f(x)dt + g(x)z\sqrt{dt}]^2 \right\}$$

So, this is what we have from the previous equation. The first equation that we have on the top and we do the Taylor expansion, we do the Taylor expansion of $G(x(t) + f(x)dt + g(x)z\sqrt{dt})$ under root dt . We do a Taylor expansion of this term around $x(t)$. So, what we and then we please note we also adjust this expression $G(x(t))$.

So, when you do the Taylor expansion of the expression in the square bracket and you deduct $G(x(t))$ the what remains is $G'(x(t))g(x)z\sqrt{dt} + \frac{1}{2}G''(x(t))(f(x)dt + g(x)z\sqrt{dt})^2 + O(dt^{3/2})$ of course 1 upon dt and dt tending to 0 is also brought forward.

(Refer Slide Time: 05:24)

$$\begin{aligned}
 F/A \frac{\partial}{\partial t} G(x(t)) &= \lim_{dt \rightarrow 0} \frac{1}{dt} \left\{ G'(x) [f(x)dt + g(x)z\sqrt{dt}] + \frac{G''(x)}{2} [f(x)dt + g(x)z\sqrt{dt}]^2 \right\} \\
 &= \lim_{dt \rightarrow 0} \frac{1}{dt} \left[G'(x)f(x)dt + G'(x)g(x)z\sqrt{dt} + \frac{G''(x)}{2} g(x)^2 z^2 dt + O((dt)^{3/2}) \right]
 \end{aligned}$$

Now, let us look at the expression $fx dt$ plus $gx z$ under root dt . Now, we need to retain here the important thing here the manoeuvre that we are going to do here is that we need to retain only those terms up to first order in dt .

So, because we are going to retain only those terms up to first order in dt , what this expression gives us you see when you square this, the fx square term with dt square will be thrown away. The $g x$ square z square dt will be retained because it is a first order in dt and the cross term will also go out because it is higher than first order in dt .

So, the only term that contributes to the square that we need to retain for our purpose that is linear in dt is gx square z square dt . The first term remains unchanged; we have not disturbed it.

(Refer Slide Time: 06:25)

- Now, we make the **Ito assumption** i.e. that when discretizing the Langevin eq we compute **$g(x(t))$ at the beginning of the time step**, i.e. using the value t , and not $(t+dt)/2$.
- If this assumption holds we can decouple $g(x(t))z$ while taking averages so that
 - $E[g(x)z] = E[g(x)]E(z) = 0$ since $E(z) = 0$
- and $E[g(x)^2 z^2] = E[g(x)^2]E(z^2) = E[g(x)^2]$ since $E(z^2) = 1$

Now, we make the Ito assumption. What is the Ito assumption? You see when we do in; when we do an integral we take the value of the integrand, for example y at a particular at the beginning of the interval and then we multiply it by dx or a Δx that is the slice the in the along the x axis in the and that in a sense gives us the area.

In other words, the important thing that I want to mention here is that we are taking the value of the integrand at the beginning of that any interval which we first of all we partition our interval here x equal to a to x equal to b into a partition. So, let us say of n distinct distinct points intervals of each of length Δx and then for each strip that we get of Δx .

We take the value of the value of y at the beginning of that particular strip and then, multiply it by Δx and then sum over all the values of n and then limit take limit n tending to infinity that is we reduce the size of the strips and that is what gives us the integral in when we talk about integration of a or a obtaining area by the process of integration.

Now, the important thing that I want to emphasise here is that we take the value of the integrand at the beginning of each partition and then multiply it by dx . Now, there is nothing really sacrosanct about it. We could as well as taken the value at the middle of the strip and then integrated around the two points constituting the strip or multiply it by dx or we could have taken the terminal value also. It is only a convention that when we do the integration, you take the value at the beginning of each time slice or partition and then multiply it by dx . This is in a sense what we call in the case of deterministic curves. It is the impact is not significant.

However when we talk about integration or calculus of stochastic variables, this becomes a significant issue because if we use one convention the Ito convention which is precisely what we have been doing so far that is we use the use the value of the integrand at the beginning of the partition.

And we or we use the stand in which convention which uses the midpoint value, we arrive at two different results and they differ by a drift term. So, we do not get exactly the same results.

So, that is the important part here. We make the Ito assumption. In other words we make the assumption that we are taking the value of the integrand at the beginning point of the various strips that constitute the and that they constitute the area to be worked out in through integration.

So, that being the case. Now, what is the implication of that? The implication of this is that we can decouple. We can decouple for example we can de couple g and z when we take the averages we can write $E g$ with the expression that we have in the red box will hold. If we use the E^2 assumption $E g x$ into z can be written as $E g x E z$ because at that point the z and $g x$ become independent and therefore, $E x y$ is equal to $E x E y$ and, but E of z is equal to 0. The expected value of z is 0 and therefore, we are the net result of this expression is 0.

But the I reiterate this holds only when the Ito assumption is used. Similarly, $E g x^2 z^2$ square is equal to $E g x^2 E z^2$ $E z^2$ square is equal to 1 and therefore, we get here E of $g x^2$ square. So, the two results that we are going to use; we are going to use the result in the red box and the result in the green box hold only under the Ito assumption.

(Refer Slide Time: 11:09)

$$\frac{\partial G(x(t))}{\partial t} = \lim_{dt \rightarrow 0} \frac{1}{dt} \left[G'(x)f(x)dt + G'(x)g(x)z\sqrt{dt} + \frac{G''(x)}{2}g(x)^2z^2dt + O((dt)^{3/2}) \right]$$
$$\mathbb{E} \left[\frac{\partial G(x(t))}{\partial t} \right] = \mathbb{E} \left[G'(x)f(x) + \frac{G''(x)}{2}g(x)^2 \right]$$
$$= \mathbb{E} [G'(x)f(x)] + \frac{1}{2} \mathbb{E} [G''(x)g(x)^2]$$

So, making use of this; making use of this what we get is if you simplify this expression, the z the second term here in the first equation the second term goes, the first term remains and the third term remains. So, the first and the third term remains and we get the expression in the blue box at the bottom of the slide.

(Refer Slide Time: 11:32)

In terms of probability distribution $P(x,t)$, expectation of arbitrary $F(x(t))$ is :

$E[F(x(t))] = \int d\omega F(\omega) P(\omega, t)$ so that

$E\left[\frac{\partial G(x(t))}{\partial t}\right] = \frac{\partial}{\partial t} E[G(x(t))] = \frac{\partial}{\partial t} \int d\omega [G(\omega) P(\omega, t)]$

$E[G'(x)f(x)] = \int d\omega G'(\omega)f(\omega) P(\omega, t)$

$E[G''(x)g(x)^2] = \int d\omega G''(\omega)g(\omega)^2 P(\omega, t)$

  10

In terms of probability distributions how do we define expected value? Probability distributions expected value of any arbitrary function is defined by the expression that is given in the red box here. Expected value of $F(x,t)$ is equal to $\int d\omega F(\omega) P(\omega, t)$. This is the definition of the expected value of $F(x)$ which has a probability distribution.

A continuous probability distribution $P(\omega, t)$ and that gives us the results that are given in the green box at the bottom of your slide. The results are quite straightforward you get them right away $E\left[\frac{\partial G}{\partial t}\right] = \frac{\partial}{\partial t} E[G(x,t)]$ that is equal to this expression.

And similarly we get the expressions for the other two right hand side terms that we have in the equation that we brought forward from the earlier slide that is this expression in the blue box.

(Refer Slide Time: 12:44)

Setting $G(x(t)) = \delta(x(t) - X)$

$$E \left[\frac{\partial \delta(x(t) - X)}{\partial t} \right] = \frac{\partial}{\partial t} \int d\omega [\delta(\omega - X) P(\omega, t)] = \frac{\partial P(X, t)}{\partial t}$$

$$E [f(x) \delta'(x(t) - X)] = \int d\omega f(\omega) P(\omega, t) \frac{d}{d\omega} [\delta(\omega - X)]$$

$$= - \int d\omega \left\{ \frac{d}{d\omega} [f(\omega) P(\omega, t)] \right\} [\delta(\omega - X)] = - \frac{\partial}{\partial X} [f(X) P(X, t)]$$

$$E [g(x)^2 \delta''(x(t) - X)] = \int d\omega g(\omega)^2 P(\omega, t) \frac{d^2}{d\omega^2} [\delta(\omega - X)]$$

$$= \int d\omega \frac{d^2}{d\omega^2} [g(\omega)^2 P(\omega, t)] [\delta(\omega - X)] = \frac{\partial^2}{\partial X^2} [g(X)^2 P(X, t)]$$

IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE 11

Now, we come to the most important step perhaps. Now, please note when we introduce $g(x, t)$ we said that it is an arbitrary function. So, we can choose that function as per our requirements as per our prescription and that is precisely what we do? We choose the function $g(x, t)$ as the function $\delta(x(t) - X)$ which as shown in the upper box blue box at the right at the top of your slide.

Now, if you make this choice; if this make this specific choice, let us see what results we get. The first result that we get is in the as shown in the red box here. This is quite straightforward the expected value of d/dt of δ of the $g(x, t)$ which is now taken as $\delta(x - X)$

X, now it becomes when you simplify this you integrate over the delta function you get dP_X upon dt . This is simply integration over the delta function.

Now, we come to the second case. The second case is expected value of $f(x) \delta(x - t)$ minus x writing it down in terms of the in terms introducing the terms of the expected value. We get the expression the second expression on the in the yellow box on the middle of your slide. This expression is introduced when we substitute the value of the or substitute the expression for the expected value.

Now, having done that we do an integration by parts. When we do an integration by parts, the derivative shifts itself and then we get a negative sign and the derivative shifts itself to the first term from the second term. Now, we do a delta integration integration over the delta function and what we get is the last term on the in the yellow box at the middle of your slide.

And similarly we through in through a two time path integration we get the expression for the second derivative of the delta function and we get the expression that we get is the right at the bottom of the slide in the green box.

Now, substituting all these terms in the expression in the equation that we have here in this expression in this equation, the equation in the red box and the and the blue box here what we get is the result that we are looking for.

(Refer Slide Time: 15:33)

Substituting these expressions in

$$\mathbf{E} \left[\frac{\partial \mathbf{G}(\mathbf{x}(t))}{\partial t} \right] = \mathbf{E} \left[\mathbf{G}'(\mathbf{x}) \mathbf{f}(\mathbf{x}) \right] + \frac{1}{2} \mathbf{E} \left[\mathbf{G}''(\mathbf{x}) \mathbf{g}(\mathbf{x})^2 \right]$$

we obtain the Fokker Planck equation

$$\frac{\partial \mathbf{P}(\mathbf{X}, t)}{\partial t} = - \frac{\partial}{\partial \mathbf{X}} \left[\mathbf{f}(\mathbf{X}) \mathbf{P}(\mathbf{X}, t) \right] + \frac{1}{2} \frac{\partial^2}{\partial \mathbf{X}^2} \left[\mathbf{g}(\mathbf{X})^2 \mathbf{P}(\mathbf{X}, t) \right]$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 12

And that result is of the form in this expression which is in the red box here which can be; which can be written more explicitly in the form of the Fokker Planck equation which is given in the green box at the bottom of your slide.

We simply substitute the values of $\mathbf{G}(\mathbf{x}, t)$. $\mathbf{G}(\mathbf{x}, t)$ was initially substituted as the delta function and then the expressions that we obtained on working out these expected values for the delta functions we make these substitutions and we get the expression for the Fokker Planck equation.

(Refer Slide Time: 16:18)

FOKKER PLANCK AS A CONTINUITY EQUATION

The Fokker Planck eq can be written as:

$$\frac{\partial p(x,t|x_0)}{\partial t} + \frac{\partial}{\partial x} \left\{ -\frac{\partial}{\partial x} \left[\frac{1}{2} A_2(x) p(x,t|x_0) \right] + A_1(x) p(x,t|x_0) \right\} = 0$$

or $\frac{\partial p(x,t|x_0)}{\partial t} + \frac{\partial j(x,t|x_0)}{\partial x} = 0$ where

$$j(x,t|x_0) = -\frac{\sigma}{2} \frac{\partial}{\partial x} \left[\frac{1}{2} A_2(x) p(x,t|x_0) \right] + A_1(x) p(x,t|x_0)$$

13

The Fokker Planck equation as a continuity equation this is a brief article very interesting. We can write the Fokker Planck equation in the form that is given in the first equation here. First equation in the red box where the expression this whole expression for the Fokker Planck equation can be summarised in the form of a two term equation.

A continuity equation in the form which is given in this second equation in the red box. This is one this has one derivative with respect to t and the other derivatives with respect to x. So, in some sense it resembles the continuity equation, right hand side is 0. So, it is a continuity equation.

So, this is where we have substituted $j(x,t|x_0)$ as the expression that we had within these curly brackets in the top equation on the in the red box on the in the middle of the slide.

(Refer Slide Time: 17:24)

Consider what happens when $t \rightarrow \infty$.
 We have $p(x, t | x_0) \rightarrow p(x)$
 assuming that a stationary PDF $p(x)$ exists.
 Correspondingly $j(x, t | x_0) \rightarrow j^{st}(x)$
 (the stationary current) given by:

$$j^{st}(x) = -\frac{\partial}{\partial x} \left[\frac{1}{2} A_2(x) p(x) \right] + A_1(x) p(x)$$

Obviously $\frac{\partial p(x)}{\partial t} = \frac{\partial j^{st}(x)}{\partial t} = 0$ so that $\frac{\partial j^{st}(x)}{\partial x} = 0$
 or $j^{st}(x)$ is a constant.

14

Now, when t tends to infinity if the system as t grows indefinitely approaches a steady state and it loses memory of its initial state, then we can write $p(x, t | x_0)$ as $p(x)$ and this is clearly independent of t .

So, the first thing that we get is that as t tends to infinity and $p(x, t | x_0)$ approaches $p(x)$ which is independent of t . So, $\frac{dp(x)}{dt} = 0$ that is one conclusion that we get from here what happens to $j(x, t | x_0)$.

Let us assume that $j(x, t)$ tends to or approaches $j^{st}(x)$. Now, clearly $j^{st}(x)$ to investigate the behaviour of $j^{st}(x)$ we make use of the continuity equation which is here if $\frac{dp(x)}{dt} = 0$. That automatically implies that $\frac{dj^{st}(x)}{dx} = 0$ and obviously, $j^{st}(x)$ is independent of t .

So, in other words what we have is x_j stationary is independent of x_j stationary is independent to t . So, x_j stationary turns out to be constant provided the system reaches a steady state where it loses memory of the initial condition.

(Refer Slide Time: 18:58)

ILLUSTRATION OF CLT

- Let each $X_i, i=1,2,\dots,n$ be uniformly distributed IIDs over the interval $(0,1)$ Then, we have:

$$1 = \int_0^1 p(x_i) dx_i = p \int_0^1 dx_i = p = p(x_i)$$

- so that $p(x_i)=1, \forall x_i \in [0,1], i=1,2,\dots,n$.

IT @DOORKEE | NPTEL ONLINE CERTIFICATION COURSE | 15

Now, I will quickly run through an example of the Central Limit Theorem. I promised at some time that we will take up the Central Limit Theorem as an example or provide an example for the illustrating the use of the Central Limit Theorem which highlights the beauty and the nuances of the theorem. So, let us just do that.

We have x_i , there are n such variables and independent identically distributed variables and these variables are uniformly distributed over the interval 0 to 1 that clearly gives us the probability density over the interval as equal to 1.

And therefore, we can write this the $p(x_i)$ the probability density function as $p(x_i)$ is equal to 1 for all $i = 1, 2, 3, 4, \dots, n$.

(Refer Slide Time: 19:56)

$$\mu_i = E(X_i) = \int_0^1 x_i p(x_i) dx_i = \int_0^1 x_i \cdot 1 dx_i = \frac{1}{2}$$
$$E(X_i^2) = \int_0^1 x_i^2 p(x_i) dx_i = \int_0^1 x_i^2 \cdot 1 dx_i = \frac{1}{3}$$
$$\sigma_i^2 = \text{Var}(X_i) = E(X_i^2) - [E(X_i)]^2 = \frac{1}{12}$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 16

And that leads us to the expected value being 1 by 2. The square of the expected value of the squares being 1 by 3 and the variance equal to 1 by 12.

(Refer Slide Time: 20:07)

Define $Z_n = \frac{\sum_{i=1}^n X_i - n\mu}{\sqrt{n\sigma^2}} = \frac{\sum_{i=1}^n X_i - \frac{n}{2}}{\sqrt{n/12}}$

The pdf of Z_n is $\rho_n(z) = \int_0^1 p(x_1) dx_1 \dots \int_0^1 p(x_n) dx_n \delta(z - z_n)$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

We now define the variable Z_n the random variables Z_n equal to summation x_i minus $n\mu$ upon under root $n\sigma^2$ we write it in the form X_i minus $n\mu$ remember μ is $1/2$. So, we have summation X_i minus $n/2$ and remember σ^2 is equal to $1/12$. So, it becomes denominator becomes under root $n/12$, the pdf was for Z_n .

Now, please note this z_n is given by the expression in the green box please note the appearance of this delta function, this delta function ensures that we only include those values of x s within the integration or only those values of X is contributed to the integration which satisfy the requirements Z is equal to Z_n where Z_n the small z_n is a realisation of capital Z_n is the particular realisation of capital Z_n .

So, by introducing this delta function we are ensuring that the constraint imposed by defining z_n is equal to $\sum x_i - n\mu$ under root $n\sigma^2$ is satisfied automatically and

only those values of $x_1 \times x_2 \times x_3 \times \dots \times x_n$ contribute to the integral where these the some of these values satisfied the requirement given in the red box, ok.

(Refer Slide Time: 21:45)

$$\rho_n(z) = \int_0^1 p(x_1) dx_1 \dots \int_0^1 p(x_n) dx_n \delta(z - z_n)$$

But pdf of each X_i is unity so

$$\rho_n(z) = \int_0^1 dx_1 \dots \int_0^1 dx_n \delta(z - z_n)$$

where $z_n = \frac{\sum_{i=1}^n x_i - \frac{n}{2}}{\sqrt{n/12}}$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

So, this is what we have from the previous slide. What we do now is because $p(x_1) \times p(x_2) \dots$ are all unity. So, we throw away the $p(x)$ s and we have the expression which is given in the blue box here. We remember z_n is equal to the expression which is given in the green box right at the right hand side of the slide.

(Refer Slide Time: 22:10)

$$\rho_n(z) = \int_0^1 dx_1 \dots \int_0^1 dx_n \delta(z - z_n)$$

Using the Fourier rep of δ function :

$$\delta(z - z_n) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dk \exp[ik(z - z_n)]$$
$$\rho(z) = \frac{1}{2\pi} \int_0^1 dx_1 \dots \int_0^1 dx_n \int_{-\infty}^{\infty} dk \exp[ik(z - z_n)]$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 19

Now, let us introduce the Fourier representation for z minus z_n . Introducing the Fourier representation for z minus z_n in the form given in the blue box what we get is the expression at right at the bottom of the slide where this green box represents the Fourier, the Fourier transform or the Fourier representation of the delta function z minus z_n .

(Refer Slide Time: 22:39)

$$\rho(z) = \frac{1}{2\pi} \int_0^1 dx_1 \dots \int_0^1 dx_n \int_{-\infty}^{\infty} dk \exp[ik(z - z_n)]$$
$$= \frac{1}{2\pi} \int_0^1 dx_1 \dots \int_0^1 dx_n \int_{-\infty}^{\infty} dk \exp\left\{ ik \left[z - \frac{\sum_{i=1}^n x_i - \frac{n}{2}}{\sqrt{n/12}} \right] \right\}$$

20

The rest is now algebra. We need to integrate this expression. The first step is to introduce z . We write z_n in its explicit form which is given here in the green box. z minus z_n is written in the explicit form given in the green box here.

(Refer Slide Time: 22:56)

$$\begin{aligned}
 F/A : \rho(z) &= \frac{1}{2\pi} \int_0^1 dx_1 \dots \int_0^1 dx_n \int_{-\infty}^{\infty} dk \exp \left\{ ik \left[z - \left(\frac{\sum_{i=1}^n x_i - \frac{n}{2}}{\sqrt{n/12}} \right) \right] \right\} \\
 &= \frac{1}{2\pi} \int_0^1 dx_1 \dots \int_0^1 dx_n \int_{-\infty}^{\infty} dk \exp \left\{ ik \left[\left(z + \sqrt{3n} \right) - \left(\frac{\sum_{i=1}^n x_i}{\sqrt{n/12}} \right) \right] \right\} \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk \exp \left[ik \left(z + \sqrt{3n} \right) \right] \int_0^1 \exp \left(-\frac{ikx_1}{\sqrt{n/12}} \right) dx_1 \dots \int_0^1 \exp \left(-\frac{ikx_n}{\sqrt{n/12}} \right) dx_n
 \end{aligned}$$

Now, our next step with this is what we obtained from the previous slide. If you look at it the second term that is minus n by 2 divided by under root n by 12 simplifies and give us under root 3 n.

Now, this expression is collected with z and written together here and the summation xis are written as a separate term. The purpose of this will be become very clear very soon. Now, that the k integral because it is independent that k integral of the terms which are independent of zs which are independent of xs. Sorry I am sorry which are independent of all the xs are taken together and are shown in the green box here and the rest of the terms which are xs integration are shown in the red box here ok.

(Refer Slide Time: 23:51)

$$\begin{aligned}
 F / A : \rho(z) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk \exp \left[ik \left(z + \sqrt{3n} \right) \right] \times \\
 &\int_0^1 \exp \left(-\frac{ikx_1}{\sqrt{n/12}} \right) dx_1 \dots \int_0^1 \exp \left(-\frac{ikx_n}{\sqrt{n/12}} \right) dx_n \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk \exp \left[ik \left(z + \sqrt{3n} \right) \right] \left(\int_0^1 \exp \left(-\frac{ikx}{\sqrt{n/12}} \right) dx \right)^n
 \end{aligned}$$

Now, each of these terms if you look carefully represents an integral of exponential minus ik x upon under root n by 12 dx each of these n integral. So, in a sense they are same integrals n times over they are same integrals n time over and that is reflected in the green box at the bottom of your slide.

(Refer Slide Time: 24:16)

$$\mathbf{I} = \int_0^1 \exp\left(-\frac{ikx}{\sqrt{n/12}}\right) dx = \frac{\sqrt{n/12}}{-ik} \left(e^{-ik \frac{1}{\sqrt{n/12}}} - 1 \right)$$
$$= \frac{\sqrt{n/3}}{-k} e^{-ik \frac{1}{\sqrt{n/3}}} \times \left(\frac{e^{-ik \frac{1}{\sqrt{n/3}}} - e^{ik \frac{1}{\sqrt{n/3}}}}{2i} \right)$$

23

Now, we do this integration let us call that integral I. So, in a sense this expression in the green box here is i to the power n let us do the integral I. The integral I when simplified gives you the expression in the red box here which can be further simplified to the expression given in the green box here.

(Refer Slide Time: 24:41)

$$F / A : I = \frac{\sqrt{n/3}}{-k} e^{-ik \frac{1}{\sqrt{n/3}}} \times \left(\frac{e^{-ik \frac{1}{\sqrt{n/3}}} - e^{ik \frac{1}{\sqrt{n/3}}}}{2i} \right)$$
$$= \frac{\sqrt{n/3}}{k} e^{-ik \frac{1}{\sqrt{n/3}}} \sin \left(k \frac{1}{\sqrt{n/3}} \right) = e^{-ik \frac{1}{\sqrt{n/3}}} \frac{\sin \left(k \frac{1}{\sqrt{n/3}} \right)}{k \frac{1}{\sqrt{n/3}}}$$

Continuing with I we continue the simplification. Further simplification enables us to write it in the form at the bottom expression on the of the slide sin exponential minus ik into 1 upon under root n by 3 sin k upon under root n by 3 divided by k upon under root n by 3 this is the expression. Please remember it is for i, but we need i to the power n.

(Refer Slide Time: 25:13)

$$F/A \rho_n(z) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dk \exp \left[ik(z + \sqrt{3n}) \right] \left(\int_0^1 \exp \left(-\frac{ikx}{\sqrt{n/12}} \right) dx \right)^n$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ik(z + \sqrt{3n})} \left[e^{-ik \frac{1}{\sqrt{n/3}}} \frac{\sin \left(k \frac{1}{\sqrt{n/3}} \right)}{k \frac{1}{\sqrt{n/3}}} \right]^n$$

And that is precisely what we do here. We do take the nth power of this expression and when we take the nth power of this expression, we simplify this. The first thing we notice that this exponential factor within this square bracket with the power n the exponential factor here gives us precisely minus under root 3 n. So, this minus this exponential factor if you simplify this, it gives us minus ik under root 3 n.

So, this i k under root 3 n and this minus i k under root 3 n when you take this n times over, these two cancel each other and what we are left with is dk e to the power ik z and this term goes out of this n n nth power integral. So, we have sin k upon under root n by 3 divided by k upon under root n by 3.

(Refer Slide Time: 26:16)

$$\begin{aligned}
 F / A : \rho(z) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ik(z+\sqrt{3n})} \left[e^{-ik\frac{1}{\sqrt{n/3}}} \frac{\sin\left(k\frac{1}{\sqrt{n/3}}\right)}{k\frac{1}{\sqrt{n/3}}} \right]^n \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikz} \left[\frac{\sin\left(k\frac{1}{\sqrt{n/3}}\right)}{k\frac{1}{\sqrt{n/3}}} \right]^n \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikz} \left[1 - \frac{1}{3!} \left(k\frac{1}{\sqrt{n/3}}\right)^2 \right]^n = \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikz} \left(1 - \frac{3k^2}{6n} \right)^n
 \end{aligned}$$

So, as I mentioned this term ik under root $3n$ and this term minus ik under root $3n$ with this power if you include this power n here, this n th power when it is brought with this factor it gives us minus under ik under root $3n$. So, this and this cancel out. We are left with ikz here which is retained and the rest is as it is and when we simplify it what we get is the expression that is given in the green box right at the bottom of the slide.

(Refer Slide Time: 26:59)

Now, $\lim_{n \rightarrow \infty} \left(1 - \frac{3k^2}{6n}\right)^n = e^{-k^2/2}$ so that $\rho(z) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikz - k^2/2}$

$= \frac{1}{2\pi} e^{-\frac{1}{2}z^2} \int_{-\infty}^{\infty} dk e^{\frac{1}{2}(ik+z)^2} = \frac{1}{2\pi} e^{-\frac{1}{2}z^2} (\sqrt{2\pi}) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}$

Put $(ik+z) = i\theta$; $dk = d\theta$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 27

Here limit of if you look at this limit n tending to infinity of this expression, in this expression 1 minus this expression is nothing, but e to the power minus $3k^2$ upon $6n$ minus $3k^2$ upon $6n$ is k^2 upon 2 . So, it is e to the power minus k^2 upon 2 .

When this n tends to infinity $1 - \frac{3k^2}{6n}$ to the power n when you take the limit n tending to infinity, it gives you e to the power minus k^2 upon 2 and therefore, we get $\rho(z)$ is equal to $\frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikz - k^2/2}$.

Now, this is clearly a simple Gaussian integral and when we do the Gaussian integral, we end up with $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}$ which is nothing, but a Gaussian with a mean of 0 and a variance of 1 which is what we wanted to establish.

(Refer Slide Time: 28:01)

Now, we move over to the next segment of our course. We now start talking about Quantum Mechanics and before we move on to Quantum Field Theory, we shall be discussing the Path Integral approach to Quantum Mechanics and once we complete the issue of Quantum Mechanics, we shall then move over to Path Integration in the context of Quantum Field Theory.

(Refer Slide Time: 28:33)

This is a recall of Davisson and Germer experiment where electrons were shot through an electron gun into screen having two slits and the interference pattern was observed on another detector screen placed behind the screen having the two slits.

(Refer Slide Time: 28:50)

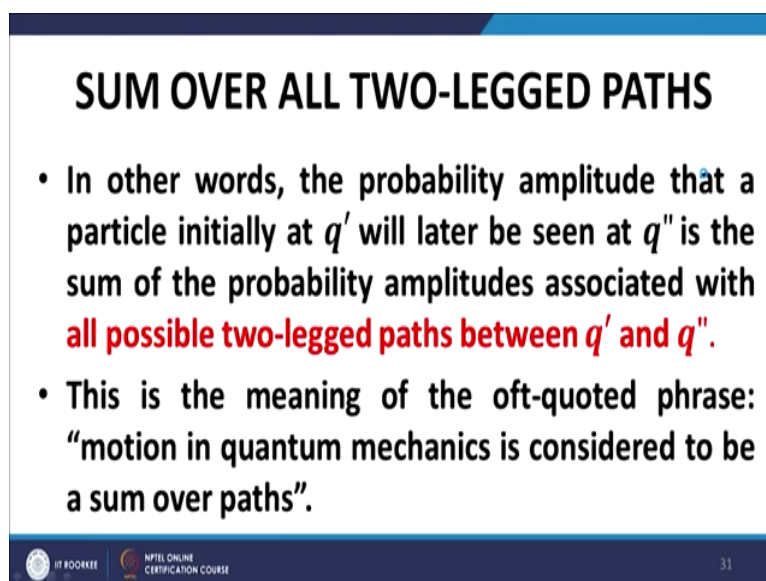

| THE TWO SLIT EXPERIMENT | |
|----------------------------------------------------------------|----------------------------------------------|
| Open up only slit A_1 | Interference bands pattern disappears |
| Open up only slit A_2 | Same |
| Open up both slits | Interference bands appear |
| One particle at a time from the source, both slits open | Same |

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 30

And the results that we found were just to recapitulate. When we open just the one slit, there is no interference. When we open the other slit, there is again no interference. When we open both the slits, then interference bands appears in the manner that is shown in this detector slide and when we even if we bombard one particle at a time from the electron gun, the interference pattern does appear.

So, these were certain conclusions, certain radical conclusions which completely or significantly revolutionise the theory behind Quantum Mechanics and which form the cornerstone or the background or the backdrop of the path integral mechanism.

(Refer Slide Time: 29:36)

SUM OVER ALL TWO-LEGGED PATHS

- In other words, the probability amplitude that a particle initially at q' will later be seen at q'' is the sum of the probability amplitudes associated with **all possible two-legged paths between q' and q''** .
- This is the meaning of the oft-quoted phrase: "motion in quantum mechanics is considered to be a sum over paths".

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 31

And now what was argued was you see what is clearly apparent from this is that if you look at the interference bands on this slide on this detector screen, they are the they represent interference patterns and the amplitudes are sums of the amplitudes of the waves that originate from the two slits in the middle in the screen in the screen let us call it the screen O1.

So, the in other words the interference patterns on the screen O2 that is the detector screen are due to the waves that propagate through the two different slits of the screen O1 and interfere and give rise to these waxes and wanes or the constructive and destructive interferences.

Now, what will happen if I increase the number of slits to 3 4 5 and so on? Well what will happen is the number of paths will increase firstly and secondly, the interference patterns that we will observe on the screen will be at any point at any point on the detector screen O2 will

be the sum of the amplitudes of the paths emerging from each of these screens, each of these slits.

So as you increase the number of slits, the number of paths increases and the, but the net result is that as far as the intensity on any point on the detector screen is concerned, it would be determined by the sum of the amplitudes of the of all the paths that emerge from the screen O1.

Now, suppose we place another screen O3 between O1 and O2 that will again and that has a number of slits in it that will again increase the number of paths, but the principle would remain the same that the amplitude or the transition amplitude at any point on the detector screen will be the sum of all the amplitudes of all the paths that reach that particular point through various various possible various possible approach points.

So, that was the that was this is what was the rationale of the quantum mechanics with the path integral formulation. The argument was that if I place an infinite number of screens between the source and the receptor S and the receptor O2 and in each of those screens if I pierce an infinite number of slits have an infinite number of slits, then the result is.

Now, the two things happened. Number 1 the as per the proposition that is established the amplitude or the intensity at any point on the on the detector screen O2 would be the sum of all possible paths starting from the source O1 ending at that particular point on the detector screen which is being investigated and why we use the word all possible paths, now we define what we mean by all possible path.

If we have an infinite number of screens and each screen has an infinite number of holes, it randomize to the situation that we are simply having no screens at all. So, in a sense what we conclude here from this argument from this argument what we conclude here.

(Refer Slide Time: 33:24)

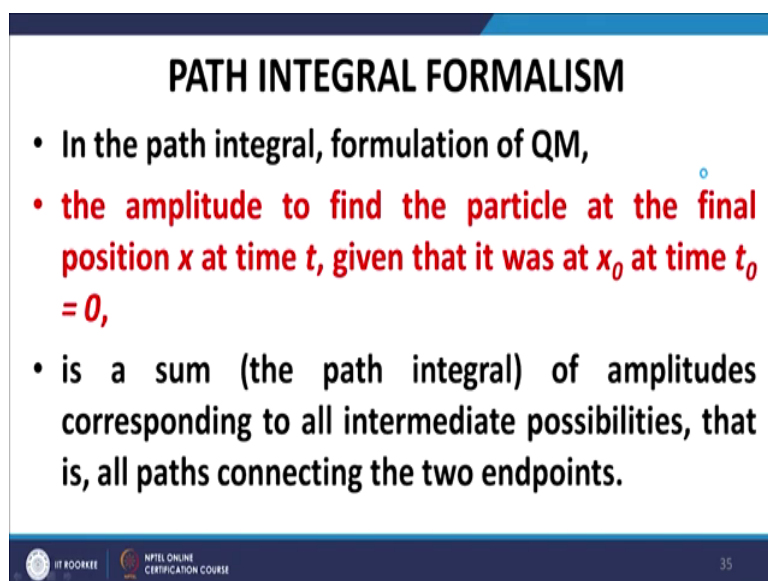

- The principle of the path integral formalism is that a particle/wave traveling a path between two events could actually be considered to be traveling along all possible paths (infinite in number) between those events.

34

The conclude the conclusion that we draw is that the path integral formalism is that where a particle or a wave travelling a path between two events could actually be considered to be travelling along all possible paths infinite in number between those two events.

(Refer Slide Time: 33:42)

PATH INTEGRAL FORMALISM

- In the path integral, formulation of QM,
- **the amplitude to find the particle at the final position x at time t , given that it was at x_0 at time $t_0 = 0$,**
- is a sum (the path integral) of amplitudes corresponding to all intermediate possibilities, that is, all paths connecting the two endpoints.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 35

Of course the important thing is also there that the amplitude to find. In other words, in other words stating the same thing again the amplitude to find the particle at a final detector point at a time t given that it was at a well defined point x_0 at time t_0 is the sum of amplitudes corresponding to all paths is that originate from the source and reach the destination.

That is the input that is the fundamental principle of the path integral formalism. Of course, each paths has you will see later has to be weighted by a particular weight factor or a phase factor rather, but we will be talking more about it. For the moment this is the principle of the Path Integral Formalism. We shall get into the nitty gritty of it from the next lecture.

Thank you.
