Lecture – 34
Schwinger Dyson EQS, Convergence of Integrals

Welcome back. So, let us continue from where we stopped before the break.

(Refer Slide Time: 00:33)

Alternative form of SD equation.
We write the action derivative as a power series

$$S'(\phi) = \sum \alpha_p \phi^p \text{ whence}$$
$$S'\left(\phi + \frac{\partial}{\partial J}\right) = S'\left(\frac{\partial W}{\partial J} + \frac{\partial}{\partial J}\right)$$
$$= \sum \alpha_p \left(\frac{\partial W}{\partial J} + \frac{\partial}{\partial J}\right)^p = \sum \alpha_p \left(\phi + \frac{\partial}{\partial J}\right)^p$$

◦

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Now, we look at an alternative form of the Schwinger Dyson equation for the generating functional. For this purpose we write the action derivative as a power series. We write the action function as a power series of the field variables.

When that is the expression given in the red box at the top of your slide and that gives us; that gives us immediately that S' of ϕ plus d by dJ will be equal to the expression that is, because ϕ is nothing but the first derivative of the generating function for the connected Green functions W . So, it follows that my state ϕ d by dJ is nothing, but S' dash dW by dJ plus d by dJ .

(Refer Slide Time: 01:18)

$$F / A : S' \left(\phi + \frac{\partial}{\partial J} \right) = \sum \alpha_p \left(\frac{\partial W}{\partial J} + \frac{\partial}{\partial J} \right)^p = \sum \alpha_p \left(\phi + \frac{\partial}{\partial J} \right)^p$$

Using SDE : $\frac{\partial^p}{(\partial J)^p} Z(J) = Z(J) \left[\phi(J) + \frac{\partial}{\partial J} \right]^p e(J)$ we get

$$Z(J) S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = Z(J) \sum \alpha_p \left(\phi + \frac{\partial}{\partial J} \right)^p e(J)$$

$$= \sum \alpha_p \frac{\partial^p}{(\partial J)^p} Z(J) = S' \left(\frac{\partial}{\partial J} \right) Z(J)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So, from the previous slide we have what the expression that is there in the first in the red box above. Now, we also have for the from the Schwinger Dyson equation that we worked out earlier for the field function, the expression that is given in the blue box and the P-th derivative of the $Z(J)$ is equal to $Z(J)$ into $\phi(J)$ plus d by dJ to the power P $e(J)$, where e is the unit operator.

When we you make use of this and you see the point is this holds for every P , this expression holds for every P and remember we have expanded the action derivative that is S dash as a power function as a power series in ϕ plus d by dJ . In other words, what I am trying to say is that for every term of the expansion of the derivative of the action this expression in the blue box would hold.

For every term of the of the power series expansion of the actions derivative which is in fact, which is the third term on your red box, in this expression or the blue box term would hold the blue box equation would hold. In other words, if you make a summation of series with respect to P , then you should get the expression that you have at the bottom of your slide by comparing the two side, by compiling the two sides.

Because if you are if you multiply both sides by α^P and then sum over p , if you multiply both sides by α^P and then sum over P . Then summation then summation can go inside this $Z J$, summation can go inside the $Z J$ and you sum over α sum over P multiply this by α and sum over this P and this is nothing, but this is nothing, but the expression on the left hand side. So, that is precisely what we have done here. That is precisely what we have done.

Putting it very simply we have multiplied both sides by α^P and then summed over P and we have got the expression that is at the bottom of your slide. And when we have that summation, when we have the summation α^P this and this expression becomes S dash d by dJ , because this expression when multiplied by α^P and summed over P will give me this expression I write at the bottom of your slide. I am encircling it as a box.

And this expression if you see, if you compare with the definition of S dash as the power series this is nothing, but S dash d by dJ of $Z J$, $Z J$ is this $Z J$.

(Refer Slide Time: 04:29)

$$F / A \quad Z(J) S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = S' \left(\frac{\partial}{\partial J} \right) Z(J)$$

Using SDE :
$$S' \left(\frac{\partial}{\partial J} \right) Z(J) = JZ(J)$$
 we get

$$Z(J) S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = S' \left(\frac{\partial}{\partial J} \right) Z(J) = JZ(J)$$

or
$$S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = J$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So, combining all the things together what do I get? I get $Z(J) S' \left(\phi + \frac{\partial}{\partial J} \right) e(J)$ is equal to $S' \left(\frac{\partial}{\partial J} \right) Z(J)$.

Now, again I use the Schwinger Dyson equation. Now, I use the Schwinger Dyson equation for the generating function for the Green functions this was the Schwinger Dyson equation for the field function. Now, I am using the Schwinger Dyson equation for the green function. What does it give me? It gives me the right hand side is equal to $JZ(J)$; the right hand side of the expression in the red box, the right hand side of the expression in the red box gives me $JZ(J)$ that means, what I get is $Z(J) S' \left(\phi + \frac{\partial}{\partial J} \right) e(J)$ is equal to this expression. And this expression is given by this is equal to this expression from the Schwinger Dyson equation.

This $JZ(J)$ because the J and the $Z(J)$ commute with each other, I can write this expression as $Z(J)$ into J and then the $Z(J)$ can be eliminated or multiplying both sides by $Z(J)$ inverse what I get is

S dash phi and d by dJ e J is equal to J. This is another expression for the Schwinger Dyson equation for the field function, Schwinger Dyson equation for the field function.

(Refer Slide Time: 05:53)

For the given ϕ^4 field : $S[\phi] = \frac{1}{2}\mu\phi^2 + \frac{1}{4!}\lambda_4\phi^4$

$$Z(J) = N \int \exp\left(-\frac{1}{2}\mu\phi^2 - \frac{1}{4!}\lambda_4\phi^4 + J\phi\right) d\phi$$

$$S'[\phi] = \mu\phi + \frac{1}{3!}\lambda_4\phi^3;$$

$$S'\left[\phi(J) + \frac{\partial}{\partial J}\right] = \mu\left(\phi(J) + \frac{\partial}{\partial J}\right) + \frac{1}{6}\lambda_4\left(\phi(J) + \frac{\partial}{\partial J}\right)^3$$

$$= \mu\left(\phi(J) + \frac{\partial}{\partial J}\right) + \frac{1}{6}\lambda_4\left(\phi(J) + \frac{\partial}{\partial J}\right)\left(\phi(J) + \frac{\partial}{\partial J}\right)\left(\phi(J) + \frac{\partial}{\partial J}\right)$$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, let us see what we get phi 4 field which is given by this expression, 1 by 2 mu sigma mu phi square plus 1 by 4 factorial lambda 4 phi to the power 4. This is the action that we are considering as the interaction action. The interaction term is this one and the free field term is the first one. The first term is the free field term and the second field is the interaction term.

Now, we get S dash of phi is equal to this expression, mu phi plus 1 by 3 factorial lambda 4 phi cubed. And therefore, S dash of phi J, phi J the phi symbol that is the phi field function plus d by dJ comes out to be in this whole expression on the right hand side.

(Refer Slide Time: 06:55)

$$\begin{aligned} &= \mu \left(\phi(J) + \frac{\partial}{\partial J} \right) \\ &+ \frac{1}{6} \lambda_4 \left(\phi(J) + \frac{\partial}{\partial J} \right) \left(\phi(J)^2 + \frac{\partial}{\partial J} \phi(J) + \phi(J) \frac{\partial}{\partial J} + \left(\frac{\partial}{\partial J} \right)^2 \right) \\ &= \mu \left(\phi(J) + \frac{\partial}{\partial J} \right) \\ &+ \frac{1}{6} \lambda_4 \left(\phi(J)^3 + \phi(J) \frac{\partial}{\partial J} \phi(J) + \phi(J)^2 \frac{\partial}{\partial J} + \phi(J) \left(\frac{\partial}{\partial J} \right)^2 \right. \\ &\quad \left. + \frac{\partial}{\partial J} \phi(J)^2 + \frac{\partial}{\partial J} \frac{\partial}{\partial J} \phi(J) + \frac{\partial}{\partial J} \phi(J) \frac{\partial}{\partial J} + \left(\frac{\partial}{\partial J} \right)^3 \right) \end{aligned}$$

(Refer Slide Time: 06:59)

$$\begin{aligned}
 &= \mu \left(\phi(J) + \frac{\partial}{\partial J} \right) + \frac{1}{6} \lambda_4 \left(\begin{aligned} &\phi(J)^3 + \phi(J) \frac{\partial}{\partial J} \phi(J) + \phi(J)^2 \frac{\partial}{\partial J} + \phi(J) \left(\frac{\partial}{\partial J} \right)^2 \\ &+ 2\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{\partial J^2} \phi(J) + \frac{\partial}{\partial J} \phi(J) \frac{\partial}{\partial J} + \left(\frac{\partial}{\partial J} \right)^3 \end{aligned} \right) \\
 &= \mu \left(\phi(J) + \frac{\partial}{\partial J} \right) + \frac{1}{6} \lambda_4 \left(\begin{aligned} &\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \phi(J)^2 \frac{\partial^2}{\partial J^2} \\ &+ \phi(J) \left(\frac{\partial}{\partial J} \right)^2 + \frac{\partial^2}{\partial J^2} \phi(J) + \frac{\partial}{\partial J} \phi(J) \frac{\partial}{\partial J} + \left(\frac{\partial}{\partial J} \right)^3 \end{aligned} \right)
 \end{aligned}$$

The rest of it work is simplifying this expression and simplifying this expression is a slightly tedious job. I have done it in the presentation step by step, and the viewers can go through it and maybe work it out themselves as well.

(Refer Slide Time: 07:09)

Hence $S' \left[\phi(J) + \frac{\partial}{\partial J} \right] e(J)$

$$= \mu \phi(J) + \frac{1}{6} \lambda_4 \left(\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{\partial J^2} \phi(J) \right)$$

The Schwinger Dyson eq is $S' \left[\phi(J) + \frac{\partial}{\partial J} \right] e(J) = J$

$$\phi(J) = \frac{J}{\mu} - \frac{\lambda_4}{6\mu} \left(\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{(\partial J)^2} \phi(J) \right)$$

8

The net result that we arrive at is the expression that is on the slide, this bottom expression on the slide. Now, when this expression operates on the on the unit function unit function, when this expression operates on the unit function the only terms that remain that survive are the expressions that are given on the right hand side.

That is the terms that have d by dJ operating on the unit functions will not contribute anything. For example, the this term will not contribute anything, this term will not contribute anything, similarly this term will not contribute anything and this term will not contribute anything.

So, the terms that contribute are this and this term contributes, this term contributes and this term contributes. So, these are the terms that will contribute and the rest of the terms will not contribute because they are acting on the unit function.

The derivative acts on the unit function and the terms that involve the derivative acting on the unit functions will not contribute because the unit function is a constant. And therefore, what we are left with is the expression that is given in the red box; this represents the Schwinger Dyson equation for the field equation for the ϕ^4 field.

The expression in the green box the S^{-1} was given by this. Now, the Schwinger Dyson equation is $S^{-1} = J$, so we put the left hand side equal to J and $\phi(J)$ is equal to J equal to this whole expression on the right hand side of the red box. And by transposition and simplification we get an expression for the field function as this J upon μ minus λ ϕ^4 upon 6μ , $\phi(J)^3$ plus $3\phi(J)\phi''(J)$ plus $\phi''''(J)$. So, this is this is now, the Schwinger Dyson equation for the for the field function for the ϕ^4 theory.

(Refer Slide Time: 09:29)

- Although this leads to very nonlinear relations between the various connected Green's functions, this form of the SD equation is actually even simpler to apply: with $\phi(J) = 0$ as a starting point. Iterating the assignment in the above equation then results in the correct form of $\phi(J)$, giving the connected Green's functions.

Now, this can obviously be solved by iteration. And as you will see later there is an intimate connection between what we have done what we have arrived at this particular equation is very significant, very important it completely describes the phi 4 theory. And it also carries the direct one to one correspondence with the Feynman diagrams. So, we shall discuss that soon. But for the moment this equation is very very important, very significant.

(Refer Slide Time: 10:00)

For the ϕ^3/ϕ^4 theory, the Schwinger Dyson eq reads :

$$\phi(J) = \frac{J}{\mu} - \frac{\lambda_3}{2\mu} \left(\phi(J)^2 + \frac{\partial}{\partial J} \phi(J) \right) - \frac{\lambda_4}{6\mu} \left(\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{(\partial J)^2} \phi(J) \right)$$

$S(\phi) = \frac{1}{2} \lambda_1 \phi^2 + \frac{1}{3!} \lambda_3 \phi^3 + \frac{1}{4!} \lambda_4 \phi^4$

For the phi 3 by 4 theory that is when we have two interaction terms we have the cubic interaction and the by quadratic interaction the Schwinger Dyson equation for the field function takes this form.

You can see there are two additional terms the rest of the equation is same as before except for these two additional terms, one involving phi J square and the second phi dash J. Even this

has a direct nexus to the Feynman diagrams in terms of 3 vertices and we shall be in discussing that as well.

But, this is basically the ϕ^4 theory where the action is given by let me write it down the action is $S[\phi]$ is equal to $\frac{1}{2} \int d^4x \mu^2 \phi^2 + \frac{1}{3!} \int d^4x \lambda^3 \phi^3 + \frac{1}{4!} \int d^4x \lambda^4 \phi^4$. So, there are two interaction terms, one involving λ^3 and the other λ^4 these are the coupling constants λ^3 and λ^4 , and of course μ is the parameter for the free field.

(Refer Slide Time: 11:33)

Now, let us go back, let us revert to the issue that I have raised in my earlier lecture also, and even in this current lecture at the beginning when we flipped the summation and the integral sign. Let us go back to that expression.

(Refer Slide Time: 11:50)

$$\begin{aligned}
 N_{\text{int}} &= \left[\int \exp(-S_{\text{int}}[\varphi]) d\varphi \right]^{-1} \\
 &= \left[\int \exp\left(-\frac{1}{2}\mu \varphi^2 - \frac{1}{24}\lambda_4 \varphi^4\right) d\varphi \right]^{-1} \\
 &= \left[\int \exp\left(-\frac{1}{2}\mu \varphi^2\right) \exp\left(-\frac{1}{24}\lambda_4 \varphi^4\right) d\varphi \right]^{-1} \\
 &= \left[\int \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24}\right)^k \varphi^{4k} \exp\left[-\left(\frac{1}{2}\mu \varphi^2\right)\right] d\varphi \right]^{-1} \\
 &= \left\{ \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24}\right)^k \right\} \left[\int \varphi^{4k} \exp\left[-\left(\frac{1}{2}\mu \varphi^2\right)\right] d\varphi \right]^{-1}
 \end{aligned}$$

If you look at this what we had done was that we had expanded you see we had two terms in the interaction, these were two terms, so the first was the free field term and the second was the interaction term. We said that lambda 4 is very small and therefore, we did an we did a series expansion in the second term, the exponential series of the second term that is exponential minus 1 by minus 1 by 4 factorial I am sorry; 1 by 4 factorial. Lambda 4 phi 4 was expanded as an exponential series and we got we got this expression in the red box as an exponential expansion is exponential expansion as an exponential series of this term minus 1 upon 4 factorial and lambda 4 phi to the power 4. This thing was expanded to get the expression in the red box.

And then we did a new then we did a gimmick. What we did was we flipped the integral sign with the summation sign. In other words, we took the summation outside and retain brought the integral inside of the summation. Now, this was this is a very technical issue, a delicate

issue and it has certain nuances. Let us explore that and before we proceed further to the case of Feynman diagrams.

(Refer Slide Time: 13:21)

CONVERGENCE ISSUES IN PERTURBATION THEORY

- Taking $\mu = 1$, the Green functions for φ^4 theory:
- $G_{2n} = H_{2n}/H_0$,
- $H_{2n} = \sum_{k \geq 0} \frac{(4k+2n)!}{2^{5k+n} 3^k (2k+n)! k!} (-\lambda_4)^k$,
- $H_0 = \sum_{k \geq 0} \frac{(4k)!}{2^{5k} 3^k (2k)! k!} (-\lambda_4)^k$.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 13

Now, if you take mu equal to 1 for simplicity because that is not really relevant at the moment, and then we can write G_n is equal to H_{2n} upon H_0 and H_{2n} is the expression that is given in the red box and H_0 is the expression that is given below in the second line. H_{2n} is the given expression given the red box, and H_0 is putting n equal to 0 you get the expression for H_0 .

(Refer Slide Time: 13:49)

- Now, for large k and fixed n the k^{th} term in H_{2n} contains the numerical coefficient:

- $\frac{(4k+2n)!}{2^{5k+n}3^k(2k+n)!k!} > A^k$ for any A .

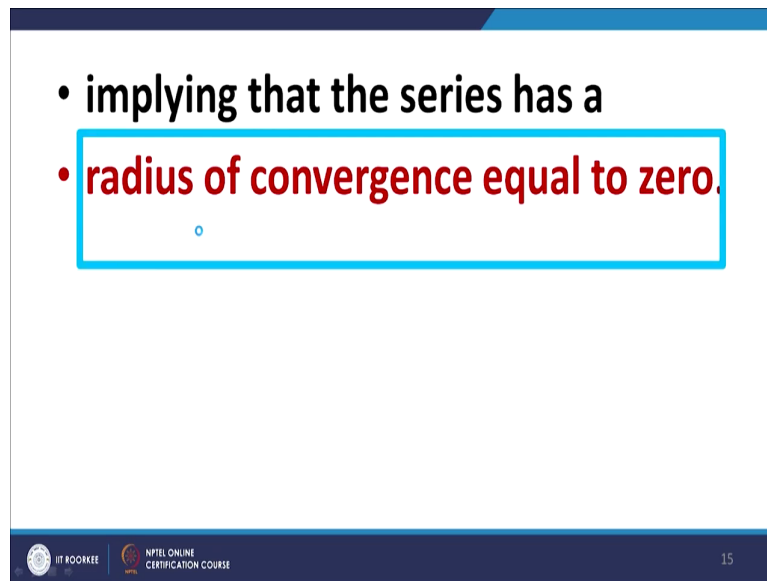

- The coefficient increases faster than A^k for any A or it grows roughly as $k!$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 14

For large k , but for fixed n let us see what is the k -th expression for in H_{2n} . The k -th expression in H_{2n} is the expression that is here in the red box. The interesting feature is if you analyze this expression this expression diverges.

Diverges in the sense it increases or it exceeds faster than, it increases faster than a to the power k , the increase of this expression is the order of k factorial you can say. It roughly grows as k factorial. It is in a sense what we call super exponential. It increases and the rate of increase of this term is of the order of k factorial.

(Refer Slide Time: 14:41)

• implying that the series has a

• **radius of convergence equal to zero.**

◦

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

So, that clearly the series is diverging and the radius of convergence of the series is zero. Let us see what is the cause of this problem.

(Refer Slide Time: 14:49)

PROBLEM CAUSE

- Actually, the cause of this problem is that in doing the perturbative expansion of
- $S(\varphi) = \frac{1}{2}\mu\varphi^2 + \frac{1}{4!}\lambda\varphi^4$, we assumed the interaction parameter λ to be small e.g. the fine structure constant in QED.

  16

You see we started with the action $\frac{1}{2}\mu\varphi^2 + \frac{1}{4!}\lambda\varphi^4$ and we assumed fundamentally that λ was small, we assumed λ to be small. And only then we did the perturbative expansion.

We expanded the second term exponential $\frac{1}{4!}\lambda\varphi^4$ as an exponential series summation series, while retaining the exponential in the first term that was on the premise that λ was small and therefore, we could expand around λ as in as a perturbative or a expansion in powers of λ .

(Refer Slide Time: 15:37)

- The dominant contribution to the integrand would come from $\exp\left(-\frac{1}{2}\mu\phi^2\right)$.
- Since this integral converges, we assumed that this being the dominant contributor, the overall series would also converge.

  17

You know we believe that the dominant contribution would come from this expression, the expression in the red box because μ was in orders of magnitude larger than λ . And therefore, it was believed that the integral, this integral because this integral converges the character of the overall expression would be dominated by this. And as a result of it the series would also converge with the flipping of the integral with the summation.

In other words, the resultant series that would be formed when we flip the integral with the summation would continue to converge because of the strong convergence of the first expression there by its convergent dominated by this expression; and because of the series being dominated by this expression and this expression converging. This expression converging, series dominated by this expression, therefore notwithstanding the fact that we

flipped us the integral and the summations and the series continues to converge that was the argument propounded.

(Refer Slide Time: 16:46)

- We flipped the integration and summation on the understanding that the resultant series would converge.
- However, as shown above, the resulting series does not converge.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

However, it does not it is clear that it does not happen that way and we have a radius of convergence of 0. Now, why is that? We see we are integrating from minus infinity to infinity.

(Refer Slide Time: 16:52)

- This is because, the range of integration is $-\infty < \varphi < \infty$.
- Hence, there would necessarily be terms in $S(\varphi) = \frac{1}{2}\mu\varphi^2 + \frac{1}{4!}\lambda\varphi^4$ wherein the interaction term dominates, howsoever small λ may be.

  19

Therefore, if you look at this expression there would be some terms irrespective of the relative orders of magnitude of mu and lambda. Irrespective of the relative orders of magnitude of mu and lambda, there would be some terms where the lambda term would dominate the mu terms.

Some permutations would definitely arise where the lambda terms dominate the mu terms. And that is bound to happen. Howsoever, small lambda would (Refer Time: 17:32).

(Refer Slide Time: 17:32)

φ^4 MODEL

$$S_{\text{int}}[\varphi] = \frac{1}{2} \mu \varphi^2 + \frac{1}{4!} \lambda_4 \varphi^4$$
$$\exp(-S_{\text{int}}[\varphi]) = \exp\left(-\frac{1}{2} \mu \varphi^2\right) \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24}\right)^k \varphi^{4k}$$
The slide contains mathematical equations for the phi^4 model. The first equation, S_int[phi] = 1/2 mu phi^2 + 1/4! lambda_4 phi^4, has a red box around the 1/4! lambda_4 phi^4 term. The second equation, exp(-S_int[phi]) = exp(-1/2 mu phi^2) * sum_{k >= 0} 1/k! (-lambda_4/24)^k phi^{4k}, has a green box around the entire summation term.

And as a result of which, as a result of which this flipping of the integral in the summation sign does not necessarily imply, does not necessarily imply that the flipped series would also converge, right.

(Refer Slide Time: 17:55)

RATIO H_{2n}/H_0 DOES NOT HELP

- The procedure of taking the ratio H_{2n}/H_0 , while it mixes terms of different order in λ_4 , does not help to repair this. It can be seen that:
- $G_2 = \sum_{k \geq 0} \sigma_k (-\lambda_4)^k, \sigma_k \sim k! (2/3)^k$
- which blows up with increasing k .

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 22

So, even if we work out the ratio H_{2n}/H_0 , we find we find that radius of convergence is of the order of k factorial. And therefore, G_2 for n equal to 1 that is the radius of the if you work out G_2 you find that σ_k is of the order of k factorial and it clearly in blows up it will not withstand, not withstanding this number. Although this number is converging, but this k the presence of k factorial makes the σ_k blow up. So, that is the problem.

(Refer Slide Time: 18:38)

- Thus, G_2 (and, it can be checked, the higher G 's) are described by series with
 - vanishing radius of convergence.
 - for we have assumed
 - the coupling constant λ_4 to be small, but positive.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 23

Thus, the net result is that there is a singularity at the origin, at this point 0 and the series has a vanishing radius of convergence.

(Refer Slide Time: 18:53)

- Therefore, the perturbative expansion is:
- not regular around $\lambda_4 = 0$, and in the set of all φ^4 theories
- the point $\lambda_4 = 0$ constitutes an essential singularity.

Now, another point; please note that we have assumed that lambda is positive, lambda 4 is positive. We assume that lambda 4 is positive indeed we had lambda 4 been negative the path integral itself would not have been defined as well at all.

(Refer Slide Time: 19:12)

CASE OF $\lambda_4 < 0$

- If λ_4 was small but negative, $\lambda_4 = -\theta, \theta > 0$
- the path integral is completely undefined since:

$$\exp[-S(\varphi)] = \exp\left[-\frac{1}{2}\mu\varphi^2 + \frac{1}{4!}\theta\varphi^4\right]$$

- which is unbounded.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

If lambda 4 were negative the path integral would not have been defined because then this part you see let us say lambda is equal to minus theta with theta positive, then the action takes this form minus 1 by 2 mu sigma square e to the power minus S phi takes the form exponential minus 1 by 2 mu sigma square plus this. And there are definitely values where the this value dominates and therefore, the sales becomes unbounded.

And therefore, when the case when lambda 4 is negative of course, the path integral become becomes undefined; but even in the case even in the case where lambda 4 is positive and small, the series is not regular at lambda 4 equal to 0 and the point lambda 4 equal to 0 represents a point of essential singularity. So, that is what disturbs the character of the series, that is what you call relates in the divergence of the series that is created by flipping the summation and the integral.

(Refer Slide Time: 20:18)

NOT CONVERGENT, BUT OSCILLATORY

- All may not be lost, however.
- The $(-\lambda_4)^k$ term comes to the rescue.
- Due to the $(-1)^k$ term, the series oscillates as the magnitude of each succeeding term increases.
- Thus, although the series is not convergent, it is asymptotic.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 26

Now, but there is some rescue, there is some hope. That hope arises from the minus lambda 4 to the power k term, this minus factor the presence of this minus 1 factor comes to the rescue and because of the presence of the minus 1 factor although the magnitude of the series is increasing, the sign is; the sign is changing though.

So, actually the series notwithstanding the fact that the magnitude is changing the series is oscillatory and this enables us to do some something about the divergence. And, that would otherwise also not have been possible at all had this minus sign not been there, at the series not been oscillatory.

The presence of the oscillatory character of the series enables us to develop a framework, to manage a framework and by which we can we can ascribe a mathematical value to this particular series. Let us see how we do it.

(Refer Slide Time: 21:20)

TRUNCATION ERROR

- Consider a series: $F(x) = \sum_{n \geq 0} c_n x^n$
- Let $F_K(x) = \sum_{n \geq 0}^{K-1} c_n x^n$. Then,
- $|\sum_{n \geq 0}^{K-1} c_n x^n - F(x)| < x^K c_K$ i.e.
- **The truncation error is smaller than the first term which is neglected.**

IIT ROORKEENITEL ONLINE
CERTIFICATION COURSE57

Consider the series $c_n x^n$, $F(x)$ is equal to this and this series. And let us say we truncate the series, we this is the series, this is a infinite series. We truncate the series at a certain value k , then it can be shown that the truncation error and that is the error representative represented due to this truncation that is this is the truncated term and this is the total series.

So, the error is the modulus value of the difference between what is the actual series and what is the series up to the truncation point that is less than x^K , c^K that is less than the term the next term which follows the truncation.

So, to repeat the error that is introduced by cutting the series at an earlier point, the series is truncated, but you are truncating it at a particular point so naturally you are creating an error you are not representing the entire series. The error that is introduced by truncating the series at a particular point is less than the value of the next following term after the truncation, that is the theorem or that is the lemma.

(Refer Slide Time: 22:47)

OPTIMAL TRUNCATION POINT

- We consider the series:
- $F(x) = \sum_{n \geq 0} (-1)^n n! x^n$ with x small.
- The truncation error will be minimum at the point at which the first term after truncation i.e. $K! x^K$ is a minimum which occurs when $x = \frac{1}{K}$.

28

So, that being the case let us consider as an example. Let us consider the series $F(x)$ is equal to summation minus 1 to the power n , n factorial x to the power n with x being small. The

truncation error will be small; will be minimum at the point at which the first term after the truncation.

Let us say the truncation is after K terms the K minus 1-th term, so the K -th term is the term that is neglected. What is the K -th term here in magnitude? That is $K x$ to the power K , K factorial x to the power K this is the K -th term. So, this is the immediately following term after the truncation and the truncation error will be less than this term.

So, we have to minimize this particular term $K x$ to the power K , and if you minimize this particular term, the minimization condition occurs to be x is equal to 1 upon K . In other words, x equal to 1 upon K gives the optimal truncation point.

(Refer Slide Time: 23:55)

• F/A: The error is: $K! x^K$ with optimum at $x = \frac{1}{K}$

• Thus, optimal truncation error $K! K^{-K}$

• Using Stirling approx.:

• $K! K^{-K} \approx e^{-K} \sim e^{-\frac{1}{x}}$

• If $x = \alpha = \frac{1}{137}$, the fine structure constant of QED, then the optimal truncation point is at the 137^{th} term and the truncation error is of order e^{-137} .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 29

And the truncation and the truncation error is given by K factorial K to the power minus K that is obtained by substituting x equal to $1/K$ in this expression. And recall this is the K -th term the term in which immediately follows the truncation.

Now, if we use Stirling approximation apart from a factor of 2π , $2\pi K$ under root the expression K factorial, K to the power minus K is of the order of e to the power minus K that is of the order of e to the power minus 1 upon x . Now, it is suppose for the QED theory where we use the x as α which is the fine structure constant as a $1/137$, we find that the truncation error would be of the order of e to the power minus 137 and would be the optimal truncation point will be 137 th term.

So, these are things which you know are so small, so small to be of insignificant. And in any case it would not be practical to work out the corrections up to 137 term in a QED series, QED theory. So, the point is that the point is, that notwithstanding the fact that we have a problem there when we flip the integral and the summation things are not that bad, and by making use of a satisfactorily or a reasonable truncation point of the series we are still able to obtain very good approximations.

(Refer Slide Time: 25:38)

BOREL SUMMATION

- Suppose that a function of a positive variable x is given by the sum
- $f(x) = \sum_{k \geq 0} c_k x^k,$
- where the coefficients c_k grow super exponentially.

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 30

Let us take another example of a technique that that remedy is the issue in another way then that is called Borel summation. Let us assume that we have the series $f(x)$ is equal to summation, k greater than equal $c_k x^k$, this is the series, infinite series again we want to work out the summation. These coefficient c_k are growing super exponentially.

We consider the sum as an alternative or as a tool we consider another series which is defined by; remember our original series was what?

(Refer Slide Time: 26:26)

- Let us consider the sum:
 - $g(x) = \sum_{k \geq 0} \frac{c_k}{k!} x^k$, $\sum c_k x^k$
 - The coefficients of $g(x)$ do not grow as rapidly as $f(x)$. We then may employ the formula
 - $\int_0^{\infty} dy \exp(-y) (xy)^n = n! x^n, n = 0, 1, 2, \dots$
 - to arrive at the rule

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 31

Original series was $c_k x^k$ of course, summation and we may be had a problem with the coefficient c_k , they were going super exponentially that is they were growing of the order of k factorial and now what we do is we divide c_k by k factorial. So, naturally the coefficients of g that is c_k upon k factorial grow relatively slowly compared to f .

Now, we work out the make use of the formula integral $dy \exp(-y) xy$ to the power n is equal to $n x$ to the power n . And this formula is quite straightforward, x to the power n can be taken outside the integral and we get the in gamma function which is easily worked out.

(Refer Slide Time: 27:16)

- $\int_0^\infty dy e^{-y} g(xy) = \int_0^\infty dy e^{-y} \sum_{k \geq 0} \frac{c_k}{k!} x^k y^k$
- $= \int_0^\infty dy e^{-y} \frac{c_0}{0!} x^0 y^0 + \dots + \int_0^\infty dy e^{-y} \frac{c_k}{k!} x^k y^k + \dots$
- $= \frac{c_0}{0!} x^0 \int_0^\infty dy e^{-y} y^0 + \dots + \frac{c_k}{k!} x^k \int_0^\infty dy e^{-y} y^k + \dots$
- $= \frac{c_0}{0!} x^0 0! + \dots + \frac{c_k}{k!} x^k k! \dots$
- $f(x)$
- **This approach is called Borel summation.**

NPTEL ONLINE CERTIFICATION COURSE 32

If you evaluate this integral $\int_0^\infty dy e^{-y} g(xy)$, let us see what we get. We get $\int_0^\infty dy e^{-y} g(xy)$, let us see what we get. On simplification, in simplification what we get is we end up with after all the manipulations straightforward manipulations we end up with $f(x)$. So, we have in other words, been able to write $f(x)$ as an alternative integral $\int_0^\infty dy e^{-y} g(xy)$. And this is this process is called Borel summation.

(Refer Slide Time: 27:57)

EXAMPLE OF BOREL SUMMATION

- Let us take $c_k = 1$, i.e. consider the series:
• $f(x) = \sum_{k \geq 0} x^k = \frac{1}{1-x}$ we immediately find that
- $g(x) = \sum_{k \geq 0} \frac{x^k}{k!} = e^x,$
- So that $\int_0^\infty dy e^{-y} g(xy)$
- $= \int_0^\infty dy e^{-y} e^{xy} = \int_0^\infty dy e^{-y(1-x)} = \frac{1}{1-x}.$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 33

And as an example of Borel summation let us look at let us look at the series $f(x)$ is equal to summation x^k scale in other words let us take c_k equal to 1 for all k . So, we look at this summation this is clearly a geometric series and with the summation is equal to $1/(1-x)$ $g(x)$ works out to $x^k/k!$ that is equal to e^x . The integral $\int_0^\infty dy e^{-y} g(xy)$ if you work it out it works out to $1/(1-x)$.

So, our Borel summation gives us the same answer as we would expect in the normal course of events. However, the Borel summation has given us a certain leeway a certain advantage. Let us look at that.

(Refer Slide Time: 28:47)

- **An important observation is to be made here.**
- **The sum for $f(x)$ converges (conditionally) for the region $|x| < 1$, whereas**
- **the sum for $g(x)$ converges everywhere, and**
- **the Borel integral converges in this case as long as $\Re(x) < 1$,**
- **thus immeasurably enlarging the region of x values where the Borel-summed version makes sense.**

34

The $f(x)$ converges conditionally for $\text{mod } x < 1$, it is quite clear that this formula, the first formula the formula in the red box holds only if $\text{mod } x$ is less than 1. And $g(x)$ of course is convergent for all values of x . So, and that is not a problem. And this integral, this integral that we have now obtained $\int_0^1 e^{-xy} g(x) dx$ is equal to $1/(1-x)$ upon x , this converges, this holds or this exists for real $x < 1$.

So, by making use of this Borel summation, we have enlarged the region of x values over which the Borel summation can make sense. From $\text{mod } x < 1$ we have increased the domain where this integral can hold to real $x < 1$.

(Refer Slide Time: 29:51)

A SECOND EXAMPLE

- **Consider the sum:**
- $F(x) = \sum_{k \geq 0} n! (-x)^k,$
- **with x positive. In that case we find**
- $G(x) = \sum_{k \geq 0} (-x)^k = \frac{1}{1+x}$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 35

So, this is an important and the important part is that, of course, there is a second example in the presentation due to sparsity of time I could not cover. But the important thing is that this issue of flipping of the summation and integral is not a trivial issue. It can be saved in certain situations. It may not be possible to save in or it justify in other situations. I have just presented an example where it can be done.

(Refer Slide Time: 30:30)

- and the Borel sum reads

- $F(x) = \int_0^{\infty} dy e^{-y} G(xy) = \int_0^{\infty} dy e^{-y} \frac{1}{1+xy}$

- $= \frac{e^{1/x}}{x} E_1\left(\frac{1}{x}\right)$ where the function:

- $E_1(z) = \int_z^{\infty} dt \frac{\exp(-t)}{t},$

is a well-defined function (exponential integral).

$F(x)$ is a function that starts (obviously) at $F(0) = 1$ and then gently decreases.

(Refer Slide Time: 30:32)

- But how do we actually compute the series $F(x)$?
- The theory of asymptotic functions provides an answer.
- Let us consider not the infinite sum $F(x)$ as given in $F(x) = \sum_{k \geq 0} n! (-x)^k$ but its truncated version:
- $E_K(x) = \sum_{k=0}^{K-1} k! (-x)^k$

NPTEL ONLINE
CERTIFICATION COURSE

37

There is another example here in which it cannot be done and that example I will leave it as for the viewers. I will put it in the presentation in any case and we will continue with Feynman diagrams.

Thank you.
