Lecture - 37
Effective Action, Renormalization

(Refer Slide Time: 00:30)

DEFINITIONS

$$P(\varphi) = N \exp[-S[\varphi]]; N = \left[\int \exp[-S[\varphi]] d\varphi \right]^{-1}$$

$$G_n \equiv \langle \varphi^n \rangle = N \int \exp(-S[\varphi]) \varphi^n d\varphi$$

$$Z(J) = \sum_{n \geq 0} \frac{1}{n!} J^n G_n = N \int \exp(-S[\varphi] + J\varphi) d\varphi$$

$$G_n = \left[\frac{\partial^n}{(\partial J)^n} Z(J) \right]_{J=0}; W(J) = \log Z(J) \equiv \sum_{n \geq 1} \frac{1}{n!} J^n C_n$$

$$\phi(J) \equiv \frac{\partial}{\partial J} W(J) = \sum_{n \geq 0} \frac{1}{n!} J^n C_{n+1}$$

3

Welcome back. So, a quick recap before we proceed further. The various equations that we have arrived at or we have formulated in the course of our discussions are presented in your first slide. The free field expression for the probability distribution and exponential minus S phi. S is the action. Action is given by for the free field it is given by mu 1 by 2 mu phi square.

We also have the expression for the Green functions as the moments of the distribution. The path integral or the generating function of the Green function is given here. And also, how to extract the Green functions from the path integral by taking successive derivatives is also here.

We also have the expression for the path in for the generating function for the connected Green functions as $\log Z$ of J . And we also have here the expression for the field function which is the first derivative of the generating function for the connected Green functions.

(Refer Slide Time: 01:32)

FREE FIELD

$$S_0[\varphi] = \frac{1}{2} \mu \varphi^2; N_0 = \left[\int \exp\left(-\frac{1}{2} \mu \varphi^2\right) d\varphi \right]^{-1} = \sqrt{\left(\frac{\mu}{2\pi}\right)}$$

$$P_0(\varphi) = \sqrt{\left(\frac{\mu}{2\pi}\right)} \exp\left(-\frac{1}{2} \mu \varphi^2\right)$$

$$Z_0(J) = \sum_{n=0}^{\infty} \frac{1}{n!} J^n G_n = \sqrt{\left(\frac{\mu}{2\pi}\right)} \int \exp\left(-\frac{1}{2} \mu \varphi^2 + J\varphi\right) d\varphi$$

$$= \exp\left(\frac{J^2}{2\mu}\right); W_0(J) = \frac{J^2}{2\mu}; \phi_0(J) \equiv \frac{\partial}{\partial J} W_0(J) = \frac{J}{\mu}$$

4

For the free field, as I mentioned the action takes the form $\frac{1}{2} \mu \varphi^2$. The normalization constant we found out is $\sqrt{\frac{\mu}{2\pi}}$ and the generating function for the Green function works out to the expression in the red box. The generating function for

the connected Green function is given in the blue box and the free field function is given in the green box.

(Refer Slide Time: 02:02)

$$\begin{aligned} & \varphi^4 \text{ MODEL} \\ S_{\text{int}}[\varphi] &= \frac{1}{2} \mu \varphi^2 + \frac{1}{4!} \lambda_4 \varphi^4 \\ \exp(-S_{\text{int}}[\varphi]) &= \exp\left(-\frac{1}{2} \mu \varphi^2\right) \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24}\right)^k \varphi^{4k} \end{aligned}$$

For the phi 4 model, we add an interaction term to the action given by $\frac{1}{4!} \lambda_4 \varphi^4$. And then we expand this interaction term on the premise that the coupling constant λ_4 is very small as a perturbation series.

(Refer Slide Time: 02:21)

$$Z_{\text{int}}(J) = N_{\text{int}} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24} \right)^k \int \varphi^{4k} \exp \left[-\left(\frac{1}{2} \mu \varphi^2 \right) + J\varphi \right] d\varphi$$

$$N_{\text{int}} = \left[\left(\frac{2\pi}{\mu} \right)^{1/2} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24\mu^2} \right)^k \frac{4k!}{4^k (2k)!} \right]^{-1}$$

(Refer Slide Time: 02:31)

$$\begin{aligned}
 G_{2n} &= N_{\text{int}} \sqrt{\left(\frac{2\pi}{\mu}\right)} \frac{1}{\mu^n} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{(4k+2n)!}{2^{2k+n}(2k+n)!} \\
 &= \frac{\frac{1}{\mu^n} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{(4k+2n)!}{2^{2k+n}(2k+n)!}}{\sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{4k!}{4^k(2k)!}} = \frac{H_{2n}}{H_0}
 \end{aligned}$$

And on that basis, we get the expression for the normalization the new normalization given in the green box here. And we also get the expression for the 2 nth Green function 2 n point Green function as the expression given on the slide, that is represented usually as H_{2n} upon H_0 where H_0 is connected to the normalization. It is the inverse of the normalization.

(Refer Slide Time: 02:48)

SCHWINGER DYSON EQUATION

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

(Refer Slide Time: 02:51)

SCHWINGER DYSON EQUATION FOR $Z(J)$

$$S'(\varphi)\Big|_{\varphi=\left(\frac{\partial}{\partial J}\right)} Z(J) = S'\left(\frac{\partial}{\partial J}\right) Z(J) = JZ(J)$$

FOR φ^4 FIELD

$$\mu\left(\frac{\partial}{\partial J}\right) Z(J) + \frac{1}{6}\lambda_4\left(\frac{\partial}{\partial J}\right)^3 Z(J) = JZ(J)$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

We then obtain the Schwinger Dyson equation. Schwinger Dyson equation for the path integral given in your red box. Schwinger Dyson equation for the specific case of the phi 4 field interaction given in the green box.

(Refer Slide Time: 03:02)

SDEs FOR FIELD OPERATOR

$$(1): \frac{\partial^p}{(\partial J)^p} Z(J) = Z(J) \left[\phi(J) + \frac{\partial}{\partial J} \right]^p e(J)$$
$$(2): S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = J$$

FOR ϕ^4 FIELD

$$\phi(J) = \frac{J}{\mu} - \frac{\lambda_4}{6\mu} \left[\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{(\partial J)^2} \phi(J) \right]$$

  10

Then we obtained these Schwinger Dyson equation for the field operators. We obtained it in two forms given as equations 1 and 2 in the red box.

(Refer Slide Time: 03:18)

SDE FOR $\phi^{3/4}$ THEORY

$$\phi(J) = \frac{J}{\mu} - \frac{\lambda_3}{2\mu} \left(\phi(J)^2 + \frac{\partial}{\partial J} \phi(J) \right) - \frac{\lambda_4}{6\mu} \left(\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{(\partial J)^2} \phi(J) \right)$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 11

And for the specific case of the phi 4 field, we got the expression in the green box. This Schwinger Dyson equation for the phi power 3 by 4 field is given in this slide. We have that extra term with the coefficient lambda 3 which is representing the phi 3 field in the action.

(Refer Slide Time: 03:35)

Now, we then of course, we also work through the Feynman diagrams. We arrived at the Schwinger Dyson equations using the approach of Feynman diagrams. While writing down the Feynman diagrams all possible Feynman diagrams excluding the vacuum bubbles. And then expressing them or evaluating each of the diagram. And we arrived at the Schwinger Dyson equation through that modulus operandi as well.

We found a very interesting conclusion. That the symmetry factors that were incorporated in the Feynman diagrams on the basis of combinatorics, turned out to be the precisely the correct symmetry factors which were dictated by the physics of the physics content of the Schwinger Dyson equation.

(Refer Slide Time: 04:25)

- The SDE for the φ^4 theory in the loop expansion is:
 - $\phi(J) = \frac{J}{\mu} - \frac{\lambda_4}{\mu} \left(\frac{1}{6} \phi(J)^3 + \frac{\hbar}{2} \phi(J) \phi'(J) + \frac{\hbar^2}{6} \phi''(J) \right)$
 - In the limit $\hbar \downarrow 0$ we have:
 - $\mu \phi^{tr}(J) + \frac{\lambda_4}{6} \phi^{tr}(J)^3 - J = 0$ or
 - $S'(\phi^{tr}[J]) = 0$
 - where $S(\phi^{tr}[J]) = \frac{1}{2} \mu \phi^{tr2} + \frac{1}{4!} \lambda_4 \phi^{tr4} - J \phi^{tr}$

NPTEL ONLINE CERTIFICATION COURSE 13

Now, we move to the limiting or the classical behavior of the phi 4 field. So, we start with the phi 4 field in the loop expansion. We introduce the concept of loops by incorporating the parameter h bar into our into the Schwinger Dyson equation. h bar represent powers of h bar corresponding to the number of loops in the Feynman diagrams.

So, the equation in the red box has two expressions with the h bar in it. One corresponding to one loop component of the Schwinger Dyson equation and the second corresponding to the two loop component of the Schwinger Dyson equation. Now, in the limit that h tends to 0 h bar tends to 0, we get the tree diagram the diagram which excludes all loop diagrams and consists only of tree diagrams.

In that situation this Schwinger Dyson equation of the red box translates to the equation that is given in the blue box. Now, if you look at it carefully, this equation in the blue box is nothing,

but the derivative of the action or rather. If I use the action that is given in the red box at the bottom of your slide, take its derivative and evaluate it at the phi tree of J I get 0.

In other words, this equation in the blue box is representing nothing, but the condition S' dash of phi tree of J is equal to 0. Where S phi the action is given by the expression in the red box.

(Refer Slide Time: 06:15)

- **Thus, the derivative of the tree (no loop) action:**
- $S(\phi^{tr}[J]) = \frac{1}{2}\mu\phi^{tr2} + \frac{1}{4!}\lambda_4\phi^{tr4} - J\phi^{tr}$
- **with respect to the field function ϕ is zero:**
- $S'(\phi^{tr}[J]) = 0.$
- **Assuming we identify \hbar as Planck's constant, $\hbar \downarrow 0$ is the classical limit.**
- **Thus, $\phi^{tr}[J]$ is the classical solution of the given action.**

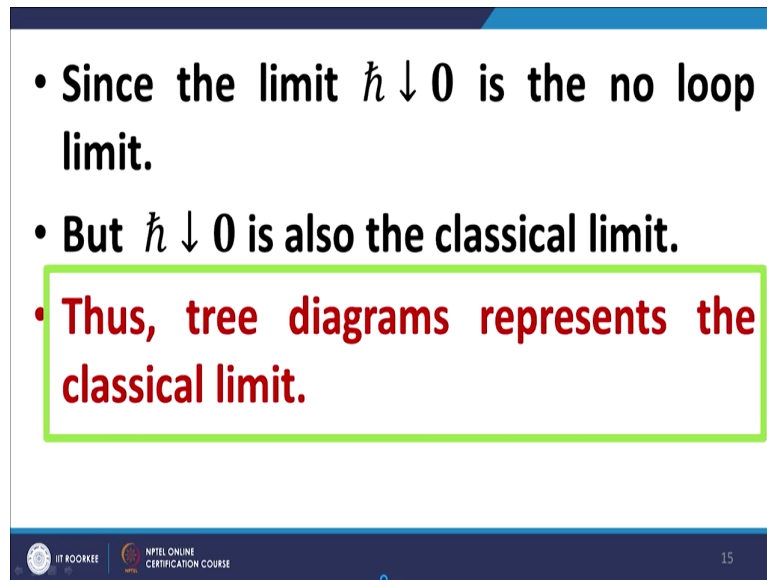

14

So, the no loop or the tree actions. This is the tree action the tree action the actions as represented that is shown in the red box, that we carried forward from the previous slide the red box slide here.

We and. If I take this derivative with respect to phi and equate it to 0, I get precisely the expression I get precisely the expression of the Schwinger Dyson equation in the limit that h bar tends to 0. So, this implies that this expression that we have obtained here is the solution

the this expression in the blue box here the expression in the blue box here is the solution of the classical solution of the given action and which is here in the red box.

(Refer Slide Time: 07:08)

- Since the limit $\hbar \downarrow 0$ is the no loop limit.
- But $\hbar \downarrow 0$ is also the classical limit.
- Thus, tree diagrams represents the classical limit.

But, we took it. The important thing here is, why we are able to say this is? Because \hbar tending to 0. If you identify \hbar with the Planck's constant. And \hbar tending to 0 then corresponds to the classical scenario or the classical limit as you may say. And therefore, when we take the limit as \hbar tending to 0. On the one hand it corresponds to the no loop expansion and on the other hand, we find that \hbar tending to 0 reproduces the classical limit.

And therefore, we can also infer that the tree diagrams represent the classical limit of the Schwinger Dyson equation or the tree portion of the Schwinger Dyson equation represents the classical limit of the complete Schwinger Dyson equation. Now, let us explore this a bit further.

(Refer Slide Time: 08:00)

$Z(J)$: SADDLE POINT APPROX

- Let us, now, consider the expansion of
- $S(\varphi[J]) = \frac{1}{2}\mu\varphi^2 + \frac{1}{4!}\lambda_4\varphi^4 - J\varphi$
- about its stationary point identified by:
- $S'[\varphi_0(J)] = 0$. We have,
- $S[\varphi(J)] = S[\varphi_0(J)] + (\varphi - \varphi_0)^2 S''[\varphi_0(J)] +$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

Let us do a Saddle Point approximation or an expansion about the saddle point of the given action. Our action is given in the red box here. We obtain the stationary point by solving the equation which is given in the blue box equating the first derivative of the action to 0. And we find. And then whatever by equating the first derivative to 0, the point that we get at the saddle point let us call it φ_0 . We expand our action S of φ around this action this saddle point or the stationary point φ_0 .

And it takes the form given in the green box. Please note that the term in the first derivative is absent, because of the condition imposed in the blue box here. The first derivative defines this saddle point. And therefore, when we are expanding around the saddle point we will get no term in the first derivative that term will be 0.

(Refer Slide Time: 09:08)

- We have $Z(J) = N \int d\varphi \exp \left[-\frac{1}{\hbar} [S(\varphi)] \right]$
- $= N \int d\varphi \exp \left[-\frac{1}{\hbar} [S[\varphi_0] + (\varphi - \varphi_0)^2 S''[\varphi_0]] \right]$
- $= N' \int d\varphi \exp \left[-\frac{1}{\hbar} [(\varphi - \varphi_0)^2 S''[\varphi_0]] \right]$

• This integral is almost a δ -function around φ_0 .
Precisely, it is a Gaussian with a variance of $\frac{\hbar}{S''[\varphi_0]} \sim 0$

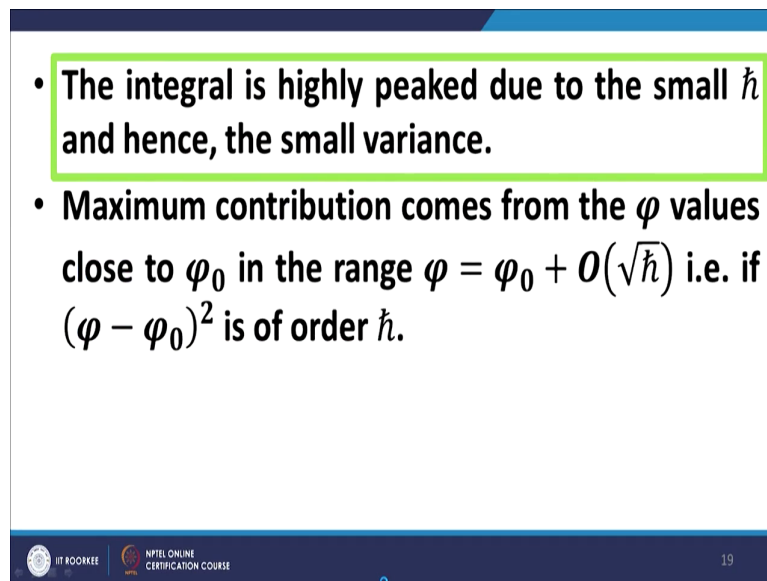

And then we have we start with the path integral and we write the path integral in this form. And now, we expand our S phi in terms of the expression that is given here in the green box. Using this expression expansion in the green box here, we write out the expression for S phi for the path integral given in the red box here.

And we absorb the first term S phi 0 with the normalization, because it is independent of phi. It is a constant and it can be absorbed in the normalization. We have a new normalization N dash and what remains inside is given here

The exponent is given by minus 1 by h bar phi minus phi 0 S double dash phi 0. Of course, we are ignoring higher derivatives of S at phi 0. Now, this integral is almost a delta function. Why do I say that its almost a delta function around the point phi 0?

Because if you look at this the variance of. It is clearly a Gaussian integral; it is clearly a Gaussian integral. If you look at the variance of this integral the variance is, \hbar upon S double dash of φ_0 . And keeping in view that \hbar is very very small we find that this variance of this Gaussian is very very small.

(Refer Slide Time: 10:40)

- The integral is highly peaked due to the small \hbar and hence, the small variance.
- Maximum contribution comes from the φ values close to φ_0 in the range $\varphi = \varphi_0 + O(\sqrt{\hbar})$ i.e. if $(\varphi - \varphi_0)^2$ is of order \hbar .

IT KOOKEE NPTEL ONLINE CERTIFICATION COURSE 19

And in other words it approximate. So, it is very close to an impulse or a delta function. It is highly peaked due to the small \hbar . And the maximum contribution therefore, comes from the φ values that are close to φ_0 . And you can express them as in the range φ_0 plus order of root \hbar , that is φ_0 plus root \hbar to φ_0 minus root \hbar which makes $\varphi - \varphi_0$ whole square of the order of \hbar .

(Refer Slide Time: 11:11)

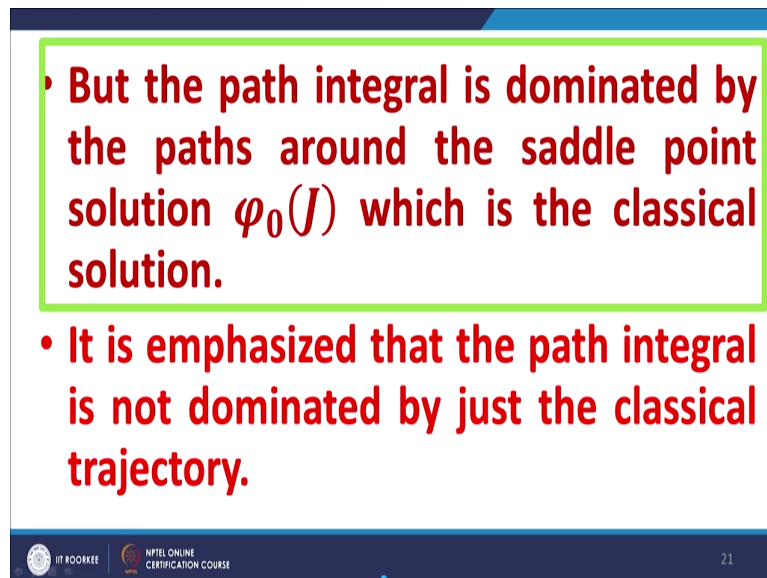

- In the above, we have obtained the saddle point approx. by setting:
- $S'[\varphi_0(J)] = 0$ (1)
- Recall that the SDE in the limit $\hbar \downarrow 0$ gave us:
- $S'(\phi^{tr}[J]) = 0$ (2)
- $\hbar \downarrow 0$ is the classical limit. Thus, $\phi^{tr}[J]$ is the classical solution of the SDE.
- Comparison of (1) & (2) shows that the saddle point solution $\varphi_0(J)$ gives us the classical solution.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 20

So, to compare, we have obtained two expressions. One expression we have obtained from starting from the action quantum action and we have obtained the expression expansion around the saddle point. We have got S' of φ_0 equal to 0. And we also obtained that in the limit that \hbar tends to 0 the tree portion of the Schwinger Dyson equation. This is under the condition of \hbar tending to 0 which is the classical limit.

Therefore, $\phi^{tr}[J]$ is the classical solution as I mentioned earlier as well of the Schwinger Dyson equation. If you compare 1 and 2 then what we find is this expression the expression number 1 also gives us the classical solution.

(Refer Slide Time: 12:01)

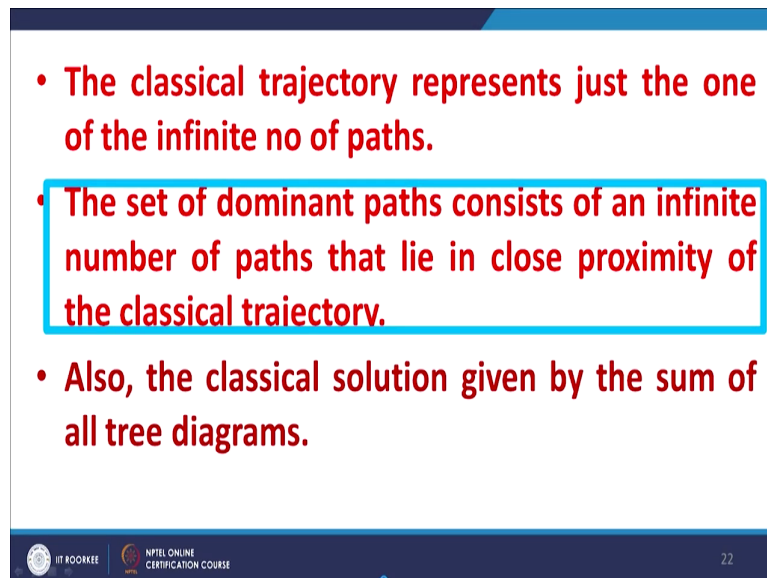

- But the path integral is dominated by the paths around the saddle point solution $\varphi_0(J)$ which is the classical solution.
- It is emphasized that the path integral is not dominated by just the classical trajectory.

IT Roorkee NPTEL ONLINE CERTIFICATION COURSE 21

Now, the and then the important thing that needs to be emphasized is that the path integral. Therefore, the classical solution of the path integral or the classical trajectory would be determined by equation number 1. That is one part.

But this trajectory only is only one of an infinite number of trajectories that constitute the entire path integral set up. The various paths that contribute dominantly or with that dominate the contribution to the ultimate path integral is our paths that are in close vicinity of the classical path. The classic. You see the point is. As I mentioned in the context of quantum mechanics as well.

(Refer Slide Time: 13:14)

- The classical trajectory represents just the one of the infinite no of paths.
- The set of dominant paths consists of an infinite number of paths that lie in close proximity of the classical trajectory.
- Also, the classical solution given by the sum of all tree diagrams.

IT Roorkee NPTEL ONLINE CERTIFICATION COURSE 22

The weight of each path is the same. But the important thing is that the path integral is dominated by paths which are close to the classical path which are very very near to the classical path. It is just it is not one path, every path has the same weight factor.

But there are a number of paths which are close to the classical path which interfere coherently constructively. That is the reason that the path integral seems to simulate to some extent or to a large extent the classical trajectory.

But I reiterate it once again, that the classical trajectory is just one path. And the set of dominant paths consists of an infinite number of paths that are in close vicinity of this stationary path or the classical path. And because they are in close vicinity of this stationary

path minor change in the action does not cause any significant change in the phase. And therefore, they interfere constructively. That is the important part.

(Refer Slide Time: 14:13)

(Refer Slide Time: 14:17)

- The SDE for the φ^4 theory is:
$$\phi(J) = \frac{J}{\mu} - \frac{\lambda_4}{\mu} \left(\frac{1}{6} \phi(J)^3 + \frac{\hbar}{2} \phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\hbar^2}{6} \frac{\partial^2}{(\partial J)^2} \phi(J) \right)$$
- In the limit $\hbar \downarrow 0$ we have a much simpler equation:
$$\mu \phi^{tr}(J) + \frac{\lambda_4}{6} \phi^{tr}(J)^3 - J = 0$$

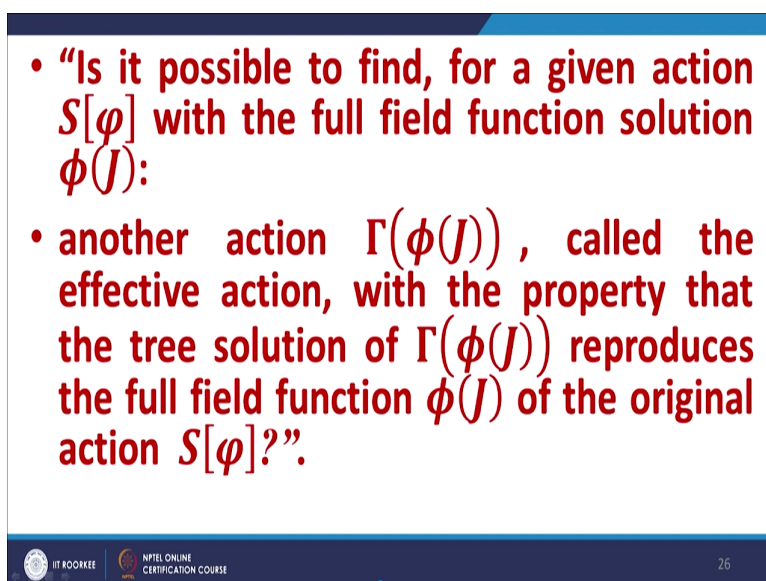

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 24

Now, we talk about a new concept which is the effective action. The Schwinger Dyson equation for the phi 4 theory is given in the red box here of course, incorporating there in the loop expansions. In the limit \hbar tending to 0 we have already seen that this equation reduces to this quantity.

(Refer Slide Time: 14:35)

- Since perturbation theory presumes that higher orders in the loop expansion are small compared to lower orders, the following question suggests itself:

(Refer Slide Time: 14:39)

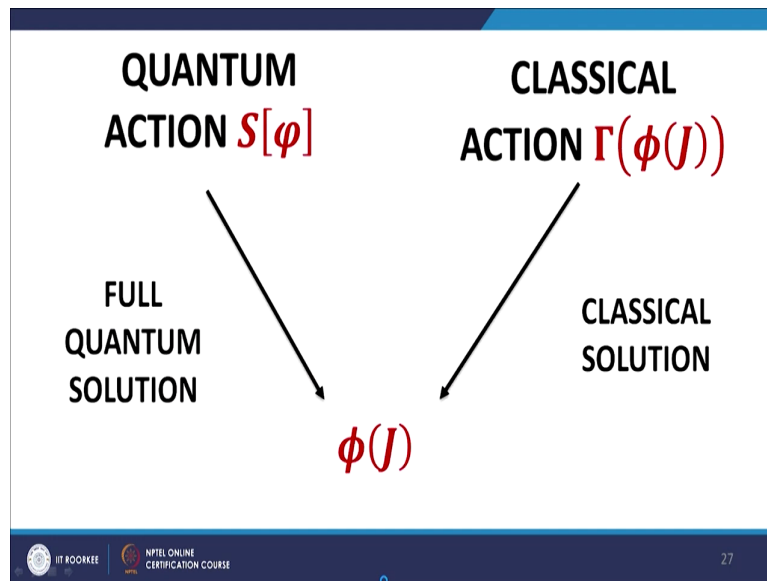

- “Is it possible to find, for a given action $S[\varphi]$ with the full field function solution $\phi(J)$:
- another action $\Gamma(\phi(J))$, called the effective action, with the property that the tree solution of $\Gamma(\phi(J))$ reproduces the full field function $\phi(J)$ of the original action $S[\varphi]$?”.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 26

Now, we ask the question; we ask the question is it possible to find, for a given action you are given a certain action S of ϕ $S[\phi]$ of J or $S[\phi]$ that has a full field solution given by the symbol $\phi(J)$: if this is the solution of corresponding to this action can we find another action?

Let us say $\Gamma(\phi(J))$. Can we find another action $\Gamma(\phi(J))$, such that the classical solution the tree level solution to this $\Gamma(\phi(J))$ reproduces the full solution $\phi(J)$ of the original action $S[\phi]$? That is the question that we attempt to address. This is what the problem is depicted here.

(Refer Slide Time: 15:25)

You have the quantum action $S[\phi]$. It has the full solution $\phi(J)$. This is the full quantum solution of the quantum action, this is what is given to you. We want to find a classical action $\Gamma(\phi(J))$; obviously, it will be a function of this $\phi(J)$ the full solution. Such that the $\phi(J)$ that we have as the full solution of the quantum action represents the classical solution of this action $\Gamma(\phi(J))$. So, that is the question we attempt to answer.

(Refer Slide Time: 16:04)

We write the given full solution or the original action

$$S(\varphi) = S_0(\varphi) - J\varphi \text{ as :}$$

$\phi_{full}(J)$ so that $S'(\phi_{full}) = 0$ or

$$S_0'(\phi_{full}) = J$$

Thus, we know $\phi_{full}(J)$ as function of J

Inverting, we write J as function of ϕ_{full}

$$J = y(\phi_{full})$$

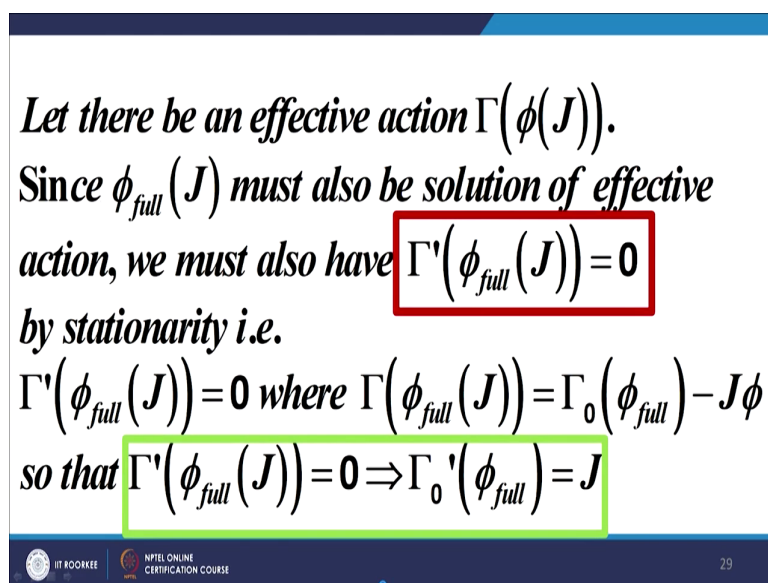

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 28

So, we write the given full solution of the original action as: $S(\phi)$ is equal to $S_0(\phi) - J\phi$, where S_0 is equal to the standard $\frac{1}{2} \mu \phi^2$, in the case of ϕ^4 theory plus $\frac{1}{24} \lambda \phi^4$. And, because $\phi_{full}(J)$ is the solution of this it is a solution of this. Therefore, we must have $S'(\phi_{full}(J)) = 0$ or $S_0'(\phi_{full}(J)) = J$.

We arrive at the equation at the expression given in the red box, because of the $\phi_{full}(J)$ is a complete solution as to the field full field solution of $S(\phi)$. That implies that $S'(\phi_{full})$ must be equal to 0 and that gives us this result. Therefore, knowing the expression given in the red box which expresses ϕ_{full} as a function of J . We can invert it and we can express J as a function of ϕ_{full} . Let it take the form given in the green box.

(Refer Slide Time: 17:12)

*Let there be an effective action $\Gamma(\phi(J))$.
Since $\phi_{full}(J)$ must also be solution of effective
action, we must also have $\Gamma'(\phi_{full}(J)) = 0$
by stationarity i.e.
 $\Gamma'(\phi_{full}(J)) = 0$ where $\Gamma(\phi_{full}(J)) = \Gamma_0(\phi_{full}) - J\phi$
so that $\Gamma'(\phi_{full}(J)) = 0 \Rightarrow \Gamma_0'(\phi_{full}) = J$*

The slide contains mathematical text with two highlighted boxes. A red box highlights the equation $\Gamma'(\phi_{full}(J)) = 0$. A green box highlights the equation $\Gamma'(\phi_{full}(J)) = 0 \Rightarrow \Gamma_0'(\phi_{full}) = J$. The slide also features logos for IIT Roorkee and NPTEL Online Certification Course at the bottom, along with the number 29.

Now, we want to obtain an action $\Gamma(\phi(J))$ such that, $\phi_{full}(J)$ is the classical solution of $\Gamma(\phi(J))$. Let us assume, because $\phi_{full}(J)$ has to be a solution of $\Gamma(\phi(J))$. We again have by stationarity requirement that $\Gamma'(\phi_{full}(J)) = 0$, which gives us the expression given in the green box.

$\Gamma'(\phi_{full}(J)) = 0$ or $\Gamma_0'(\phi_{full}) = J$. This is what we get, because of this stationarity requirement imposed on the action $\Gamma(\phi(J))$. Because $\phi_{full}(J)$ is a solution of this action $\Gamma(\phi(J))$.

(Refer Slide Time: 18:09)

Now, $\Gamma_0'(\phi_{full}) = J$ so that $\Gamma_0(\phi) = \int d\phi J = \int d\phi y(\phi_{full})$

On partial integration, we get

$$\begin{aligned} \Gamma_0(\phi) &= \int d\phi y(\phi_{full}) = \phi_{full} y(\phi_{full}) - \int d\phi \phi_{full} \frac{dy}{d\phi} \\ &= \phi_{full} y(\phi_{full}) - \int \phi_{full} dy = \phi_{full} J - \int \phi_{full} dJ \\ &= \phi_{full} J - \int \hbar \frac{dW}{dJ} dJ = \phi J - \hbar W \end{aligned}$$

where J is now interpreted as a function of ϕ_{full} .

The transition from $W(J)$ to $\Gamma(\phi)$ is called Legendre transformation.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 30

Now, from here what we get is from the previous slide what we get is. Γ_0 dash ϕ full is equal to J and that gives us; that gives us Γ_0 of ϕ is integral of $d\phi$ of integral $d\phi$ of J . From this expression we immediately obtain in the expression given, but the integration is with respect to ϕ the integrand is J . We need to; we need to change variables to ϕ . We already have the expression with us we have this expression, because of this inversion given in the green box here.

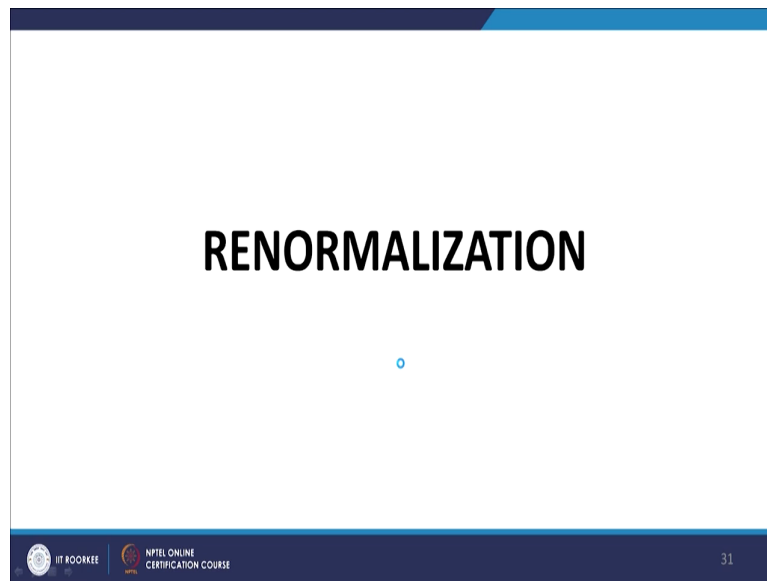

We make use of this and we write J as y of ϕ of full, where J is equal to y ϕ full which we had obtained by this stationarity of the quantum action right. So, now, we do an integration by parts. When we do an integration by parts. What we get is, the expression ϕ full y of ϕ full minus integral of $d\phi$ ϕ full dy by $d\phi$. Taking y ϕ full as one function and one as the other function.

First function y as one function and one as the other function we do an integration by part. First function y into integral of the second function minus integral of derivative of the first function into integral of the second function. So, now, if you look at this. The first expression you taken as it is the second expression $d y$ is equal to $d J$.

So, we simply substitute this expression integral ϕ full $d \phi$ $d \phi$ cancels we get integral ϕ full $d y$ which is nothing, but integral ϕ full $d j$. But ϕ full is nothing, but ϕ is the field function and field function is the first derivative of the generating function for the connected diagram. So, we can write ϕ full as $d W$ upon $d J$ and of course, with the loop parameter \hbar . And this whole thing simplifies to give us ϕJ minus \hbar bar W .

When you simplify this integral you get ϕJ minus \hbar bar W where J is now a function of ϕ full. And this whole thing is called is a Legendre transformation.

(Refer Slide Time: 20:56)

Now, we come to a new topic Renormalization. This is one of the most fascinating topics that we encounter in quantum field theory. In the context of zero dimensional quantum field theory the approach is somewhat abridged. But nevertheless, it brings out the nuances that are associated with renormalization. I will go through it slowly, because it is a bit technical, but it is very very fascinating.

(Refer Slide Time: 21:30)

**RENORMALIZATION: MATHEMATICIAN'S
PERSPECTIVE**

- Given the parameters, μ , λ_3 and λ_4 of the action, to compute the connected Green's functions. This may be depicted by the following problem:

$$\mu, \lambda_3, \lambda_4 \rightarrow C_1, C_2, C_3, C_4, C_5, C_6, C_7, \dots$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 32

So, let us look at the mathematicians perspective of what we are what we try to do in quantum field theory. And what we have tried to do so far in the context of perturbation expansions for finding out the Green functions and connected Green functions of the theory.

The mathematician would view it as you are given certain inputs. The inputs would consist of the mass and the coupling constants of the theory. And using this mass and coupling constants the mathematician would like to arrive at expressions for the various Green functions various connected Green function C_1 C_2 C_3 and so on. So, that is the mathematicians problem and that is what by and large we have been addressing so far.

(Refer Slide Time: 22:15)

THE PHYSICIST'S PERSPECTIVE

- From the physicist's perspective,
- We measure the values of some connected Green's functions, usually from scattering data;
- We, then, determine the values of the action's parameters using the above data on connected Green's functions;
- Predict some other connected Green's functions, which we shall call prediction processes.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 33

For the physicist; however, it becomes a slightly different perspective. From the physicist perspective what we have is we measure certain values of some connected Green functions using scattering experiments. On the basis of those scattering experiments, we get experimental values of certain connected Green functions.

Using those connecting connected Green functions. The next step is we work out the parameter values the bare parameter values of the inputs that go into the action. That is the mass and the coupling constants various coupling constants, that is the second step. And then on the basis of those mass and coupling constant that we have estimated using the experimental results, we try to predict try to work out the more connected Green functions and that is the.

And then of course, we may we may arrive at expressions for higher order Green functions. And experiments may then be devised to study or to work out to calculate these higher order Green functions and see, whether they relate to or whether they coincide with the Green function that we have worked out and find out whether the theory is correct or the theory needs some modifications or needs to be abandoned.

So, this is the physicist's perspective on this issue. Having outlined the difference in perspective between the mathematician and the physicist.

(Refer Slide Time: 23:54)

- Thus, the physicist's perspective is depicted by:

$$C_k^{\text{exp}} = C_k, k = 1, 2, 3, 4$$

$$\rightarrow \mu, \lambda_3, \lambda_4 \rightarrow C_5, C_6, C_7, \dots$$

- Here, the quantities $C_k^{\text{exp}} \neq C_k; k = 1, 2, 3, 4$. stand for the experimentally observed values of the connected Green's functions.

We in the form it is a. The physicist perspective can be depicted here. We work out the experimental the certain number of connected Green function say, $C_1 C_2 C_3 C_4$ experimentally.

We get experimental values. They form our inputs to determine the various parameters the bare parameters of the action. And these bare parameters of the action which we worked out on the basis of inputs received from the experiments can are then used to work out more Green functions. And these Green functions are then compared with further experiments to arrive at the veracity accuracy of the theory.

Now, the issue of renormalization arises, because we do not we as we have seen we do not are or we are not able to exactly solve or solve the theory even the simplest ϕ^4 theory in a closed form. We invariably use the perturbation theory as a mechanism of estimating or approximating the Green functions up to a certain level.

That raises the issue of the point at which the truncation of the Green functions is turned. A truncation of the expansion of the series expansion is done at for loop level the various quantities are calculated. That is very important and that any inconsistency there would be reflected in accuracy. And that is where the role of renormalization comes into play. Let us see how? Let us suppose that we worked out $C_1 C_2 C_3$ and C_4 at a certain level of a loop certain loop level. Let us say at the p th loop level.

We have got $C_1 C_2 C_3 C_4$ values from experiment. Using the expressions for $C_1 C_2 C_3 C_4$ at say the p th loop level. We work out the expressions for the various bare parameters of the action at the p th loop level. And on that basis, we work out the values of the other connected Green functions say $C_5 C_6 C_7$ and so on at the p th loop level so far so good.

And of course, then it can be compared with experiments and so on. Now, let us say assume that it becomes possible or somebody exceptionally ingenious is able to work out $C_5 C_6 C_7 C_8$ at the $p + 1$ th loop level work out expressions for $C_5 C_6 C_7 C_8$ at the $p + 1$ th loop level.

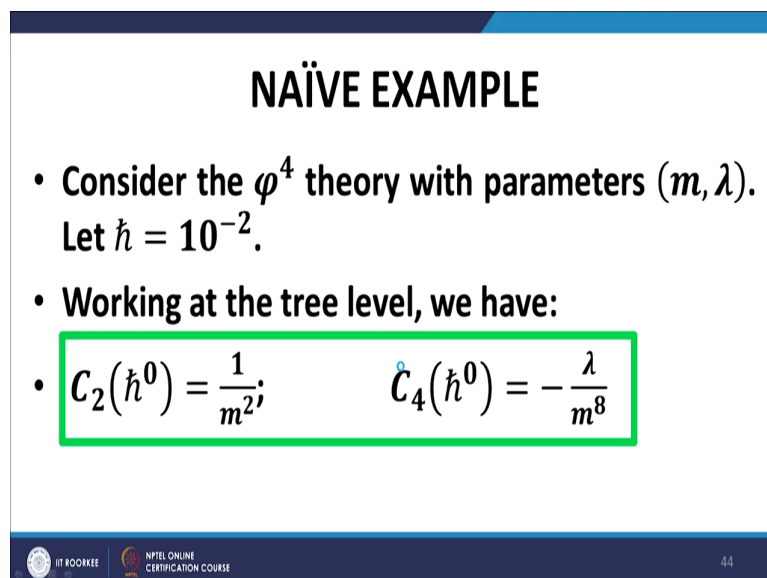

Now, the question then arises. Whether we can use the data at the p th loop level for μ the μ and the coupling constants as inputs to the formula at obtained for $C_5 C_6 C_7 C_8$ at the $p + 1$ th loop level? And that is where the question of renormalization makes its presence.

The answer is no. If we are working out the connected Green functions $C_5 C_6 C_7 C_8$ at the $p+1$ th loop level or if we have corrected, let us say $C_5 C_6 C_7 C_8$ from the p th loop level to the $p+1$ th loop level. It is absolutely imperative that we use as inputs to those $p+1$ th corrected $C_5 C_6 C_7 C_8$.

The values of μ λ_1 λ_3 λ_4 and so on. That are also corrected to the $p+1$ th loop level. That is fundamental. The loop level must be consistent otherwise what will happen is, we will end up with divergences. And these divergences will distort the results of assessment or evaluation of the theory.

So, that is the how the problem arises. Now, let us see let us work practically work out through a very naive example and see what actually happens?

(Refer Slide Time: 28:48)

NAÏVE EXAMPLE

- Consider the φ^4 theory with parameters (m, λ) .
Let $\hbar = 10^{-2}$.
- Working at the tree level, we have:
- $C_2(\hbar^0) = \frac{1}{m^2}; \quad \hat{C}_4(\hbar^0) = -\frac{\lambda}{m^8}$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 44

We have got the phi 4 theory. This is an example please note this. This is a. You got a phi 4 theory. There are only two parameters m and λ and μ are related \hbar is taken as 10 to the power minus 2. Now, working at the tree level we have worked out the formula for C_2 and C_4 .

$\hbar = 10$ means that we were working at the tree level. So, we work the formula for C_2 is 1 upon m square. This can be done on the basis of the Feynman diagrams. C_4 we obtain as minus λ upon m to the power 8. So, to repeat. We are having a phi 4 theory. The parameters are m and λ . \hbar we have taken as 10 to the power minus 2 and the formula for C_2 and C_4 we know, at the tree level are 1 upon m square and minus λ upon m to the power 8.

(Refer Slide Time: 29:54)

- Since the theory involves only two parameters, only two experimental measurements are required to fix the parameters.
- Let us assume that the experiments return:
 $C_2^{exp} = 1; C_4^{exp} = -2$
- These values yield :
 $m(\hbar^0) = 1; \lambda(\hbar^0) = 2$

  NPTEL ONLINE CERTIFICATION COURSE 45

Now, because the theory involves two only two parameters, m and λ . In principle at least two experimental measurements are sufficient to fix the parameters. We do the two measurements experimentally and what we find is that C_2 experimental.

The experimental value of C_2 is found to be 1 and the experimental value of C_4 is found to be minus 2. These are input. These are these are on practically worked out experiment scattering experiments that have given us these inputs as C_2 experiment is 1 and C_4 experiment is minus 2.

So, obviously, these will not change. These are actually worked out through experiments done in the lab. Now, on the basis of these values when we input into these equations in the equations that are given in the green box. When we input those experimental values. We arrive at m at the tree level is equal to 1, λ at the tree level is equal to 2.

(Refer Slide Time: 31:03)

- Predict $C_6(\hbar^0) = 10 \frac{\lambda^2}{m^{14}} = 40$
- Now, the one-loop level corrected prediction with 0-loop parameter values is:
 $C_6(\hbar^1) = 10 \frac{\lambda^2}{m^{14}} - 80 \frac{\hbar \lambda^3}{m^{18}} = 33.60$
- However, this is not the correct result.
- For, if we are calculating the Green functions to one loop, the parameters must also be estimated to one loop. The values used here are tree level values.

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 46

So, now we what we do is we predict C_6 at the tree level. And we find that it is given by $10 \lambda^2$. Please note \hbar is equal to 10 to the power minus 2 . So, we predict C_6 and we find C_6 of at the tree level equal to $10 \lambda^2$ upon m to the power 14 which we find as 40 . So, this is so far so good. Everything is done at the tree level there is no inconsistency. It is fine.

Now, what happens is. Let us say, we work we want to work out or somebody has worked out the C_6 value at one loop level. When the C_6 values that the 6 point Green function is worked out at one loop level. The expression is found to be given in the red box here and the value on the basis. Now, this is important this is very important. Value of $C_6 \hbar^1$ on the basis of the parameters m and λ worked out at the tree level that is at \hbar^0 level works out to 33.60 .

This is. Please keep track of the figures. C_6 at \hbar^0 was found to be 40 this was correct this was the value of C_6 at \hbar^0 . Then, we worked out C_6 at one loop level we use the formula for C_6 worked out at one loop level, but we inputted the bare parameters of the action into this formula which were worked out at the tree level and we found the value to be 33.60 right.

Now, what we did what we do is. We go right back and we go back to C_2 and C_4 . And we correct our C_2 and C_4 formula which were earlier at the tree level.

(Refer Slide Time: 33:08)

- We, therefore, introduce the one loop level corrections in C_2, C_4 to obtain the one loop corrected parameters:
- $C_2(\hbar^1) = \frac{1}{m^2} - \frac{\hbar\lambda}{2m^6}; C_4(\hbar^1) = -\frac{\lambda}{m^8} + \frac{7\hbar\lambda^2}{2m^{12}}$
- Using the experimental values:
- $C_2^{exp} = 1; C_4^{exp} = -2$
- The updated values of the parameters are obtained as:
- $m(\hbar^1) = 0.995; \lambda(\hbar^1) = 2.056$

47

And we work them out rework them out at the one loop level. We work out C_2 and C_4 . Please note these are not the experimental values. Experimental values continue to remain what they are.

The formula for the C_2 and C_4 are reworked and we incorporate there in the correction due to the first loop. And we find that the corrections are given by. For C_2 we find the correction as $\hbar \lambda$ upon $2m$ to the power 6. And for C_4 we find the correction to be $7 \hbar \lambda^2$ upon $2m$ to the power 12.

We retain this experimental values as 1 and minus 2 that we started with. We input them into this new formula that we have derived using the first order corrections in \hbar . And we find $m \hbar$ is equal to 0.995 and $\lambda \hbar$ is equal to 2.056. So, these are two values that we are we have now obtained the bare parameters to reaction corrected at the one loop level.

(Refer Slide Time: 34:23)

- We can, now, use these updated values of the parameters at one loop to obtain the value of:

$$C_6(\hbar^1) = 10 \frac{\lambda^2}{m^{14}} - 80 \frac{\hbar \lambda^3}{m^{18}} = 38.92$$

- Interesting, due to the renormalization, the predicted value of $C_6(\hbar^1)$ has changed from 33.60 to 38.92 i.e. the gap between the $C_6(\hbar^1)$ and $C_6(\hbar^0)$ has narrowed down.

And when we input these new parameters the updated parameters the revised parameters at the one loop level into the expression for C_6 , which is also at the one loop level we get the

expression of 38.92 right. So, the discussion on this result set of results. I will take up after the break.

Thank you.
