Lecture - 38
Renormalization in O-D

Welcome back. So, we are talking about Renormalization. Let us quickly recap the example.

(Refer Slide Time: 00:31)

NAÏVE EXAMPLE

- Consider the φ^4 theory with parameters (m, λ) .
Let $\hbar = 10^{-2}$.
- Working at the tree level, we have:

$C_2(\hbar^0) = \frac{1}{m^2}; \quad C_4(\hbar^0) = -\frac{\lambda}{m^8}$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 44

We are talking about in phi 4 theory. The two parameters are m and lambda, h bar is taken as 10 to the power minus 2.

(Refer Slide Time: 00:39)

- Since the theory involves only two parameters, only two experimental measurements are required to fix the parameters.
- Let us assume that the experiments return:
 $C_2^{exp} = 1; C_4^{exp} = -2$
- These values yield :
 $m(\hbar^0) = 1; \lambda(\hbar^0) = 2$

IT Roorkee NPTEL ONLINE CERTIFICATION COURSE 4

The expression for the 2 point and the 4 point functions at tree level and even in the green box. And we worked out the experimental values of these two Green functions C_2 and C_4 , and we found them to be 1 and minus 2. These values at the tree level, if we remain at the tree level give gave us the value of m and λ as 1 and 2, respectively.

(Refer Slide Time: 01:05)

- Predict $C_6(\hbar^0) = 10 \frac{\lambda^2}{m^{14}} = 40$
- Now, the one-loop level corrected prediction with 0-loop parameter values is:
 $C_6(\hbar^1) = 10 \frac{\lambda^2}{m^{14}} - 80 \frac{\hbar \lambda^3}{m^{18}} = 33.60$
- However, this is not the correct result.
- For, if we are calculating the Green functions to one loop, the parameters must also be estimated to one loop. The values used here are tree level values.

o

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 5

On that basis, we worked out the value of C_6 that the 6 point green function and we found it to be 40. We thereafter increased the level of perturbation from 0-loop level that is the tree level to the one loop level for C_6 . And we found that if we use the existing values of m and λ that we have obtained earlier, that we obtained earlier m equal to 1 λ equal to 2, we get the value of C_6 at the one loop level as 33.60. That is what we obtained.

(Refer Slide Time: 01:47)

- We, therefore, introduce the one loop level corrections in C_2 , C_4 to obtain the one loop corrected parameters:
- $C_2(\hbar^1) = \frac{1}{m^2} - \frac{\hbar\lambda}{2m^6}$; $C_4(\hbar^1) = -\frac{\lambda}{m^8} + \frac{7\hbar\lambda^2}{2m^{12}}$
- Using the experimental values:
- $C_2^{exp} = 1$; $C_4^{exp} = -2$
- The updated values of the parameters are obtained as:
- $m(\hbar^1) = 0.995$; $\lambda(\hbar^1) = 2.056$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 6

Then, we went backwards. We worked out the formula for C_2 and C_4 also at one loop level. And we have introduced corrections for the one loop for the first loop level and we found on that basis we using C_2 and C_4 formula at the one loop level refund m \hbar^1 to be 0.995 and λ at the one loop level as 2.056. If we use these new values for working of the C_6 at the one loop level we find it to be 38.92.

(Refer Slide Time: 02:17)

- We can, now, use these updated values of the parameters at one loop to obtain the value of:
- $C_6(\hbar^1) = 10 \frac{\lambda^2}{m^{14}} - 80 \frac{\hbar \lambda^3}{m^{18}} = 38.92$
- Interesting, due to the renormalization, the predicted value of $C_6(\hbar^1)$ has changed from 33.60 to 38.92 i.e. the gap between the $C_6(\hbar^1)$ and $C_6(\hbar^0)$ has narrowed down.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

Now, the important things are that firstly, this process shows how renormalization should be carried out. If you are going to work out C_6 at one loop level you must use the bare parameters in the action, also worked out at one loop level. In other words, the Green function that have been used for working out the action parameter must also have a consistent or an equivalent level of accuracy, level of perturbation to the Green functions that are being predicted. So, that is what renormalization mandates.

The second interesting part is that when we use the action parameters at the tree level we got the value of C_6 at one loop level as 33.60, and when we use the expression for the action parameters at one loop level and worked out C_6 also at one loop level we got 38.92.

Now, obviously, it is very clear from very obvious from this point that the difference between the between the C_6 values without renormalization is much much more than the difference

between the values at successive levels of perturbation worked out after renormalization. So, that is important. Renormalization tends to make the values converge rather than diverge, that is a very important aspect that and that was formalized in the process of working out the theory of renormalization.

(Refer Slide Time: 03:25)

A SECOND EXAMPLE

- As another example of the renormalization program, we shall investigate ϕ^3 theory.
- To order $O(\hbar)$ in perturbation theory the first few connected Green's functions are given by:

o

IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE 8

Let us take another example, slightly more involved example. We again you in this case we use the phi 3 by 4 theory.

(Refer Slide Time: 04:38)

$$C_1 = \hbar \left(-\frac{\lambda_3}{2\mu^3} \right) + O(\hbar^2)$$
$$C_2 = \hbar \left(\frac{1}{\mu} \right) + \hbar^2 \left(-\frac{\lambda_4}{2\mu^3} + \frac{\lambda_3^2}{\mu^4} \right) + O(\hbar^3)$$
$$C_3 = \hbar^2 \left(-\frac{\lambda_3}{\mu^3} \right) + \hbar^3 \left(-\frac{4\lambda_3^2}{\mu^6} + \frac{7\lambda_3\lambda_4}{\mu^5} \right) + O(\hbar^4)$$
$$C_4 = \hbar^3 \left(-\frac{\lambda_4}{\mu^4} + \frac{3\lambda_3^2}{\mu^5} \right) + \hbar^4 \left(\frac{24\lambda_3^4}{\mu^8} + \frac{7\lambda_4^2\lambda_4}{2\mu^6} - \frac{59\lambda_3^2\lambda_4}{2\mu^7} \right) + O(\hbar^5)$$
$$C_5 = \hbar^4 \left(\frac{10\lambda_3\lambda_4}{\mu^6} - \frac{15\lambda_3^3}{\mu^7} \right) + \hbar^5 \left(\frac{605\lambda_4\lambda_3^3}{2\mu^9} - \frac{192\lambda_3^5}{\mu^{10}} - \frac{80\lambda_4^2\lambda_3}{\mu^8} \right) + O(\hbar^6)$$

NPTEL ONLINE
CERTIFICATION COURSE

9

And, the values of the various green function connected Green functions to first order in perturbation are given in your slide C 1, C 2, C 3, C 4 and C 5.

(Refer Slide Time: 04:51)

- Let us assume that the experimental values of the connected Green's functions $C_{2,3,4}^{exp}$ have been measured, with negligible experimental error for simplicity.
- Recall that this theory has three parameters $\mu, \lambda_3, \lambda_4$ and hence we require a minimum of three measurements to fix the three parameters.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE

10

Now, we assume that the experimental results, we experiments carried out scattered, scattering experiments are carried out and connected Green functions C_2, C_3 and C_4 experimental were measured and obtained. And these experimental values were used for calculating μ, λ_3 and λ_4 at the first level of perturbation, at the one loop level of perturbation.

(Refer Slide Time: 05:17)

- For purposes of illustration, we shall assume that these values are

$$C_2^{\text{exp}} = \hbar, C_3^{\text{exp}} = -\hbar^2, C_4^{\text{exp}} = 2\hbar^3$$

And let us assume that we get the experimental values as C_2 as \hbar , C_3 as minus \hbar^2 and C_4 as $2\hbar^3$.

(Refer Slide Time: 05:33)

- Using the values: $C_2^{\text{exp}} = \hbar$, $C_3^{\text{exp}} = -\hbar^2$, $C_4^{\text{exp}} = 2\hbar^3$
- And the expressions for $C_{2,3,4}$ to lowest order in \hbar :

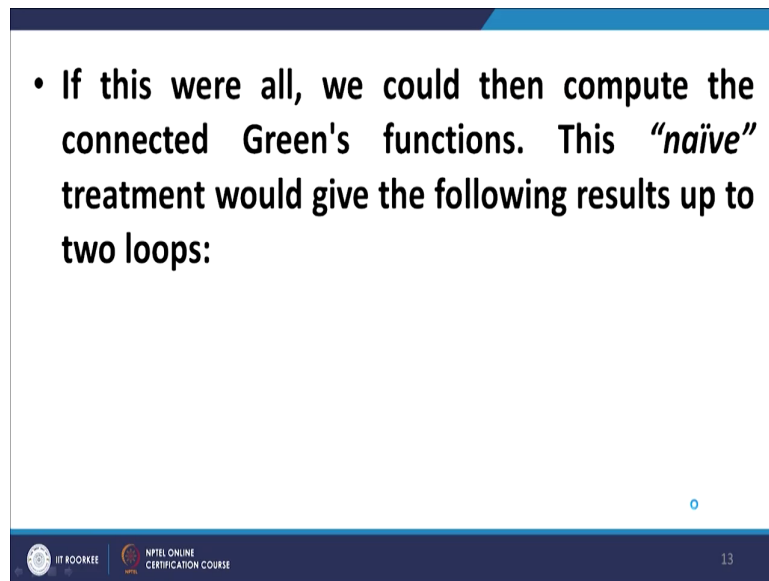

$$C_2 = \hbar \left(\frac{1}{\mu} \right); C_3 = \hbar^2 \left(-\frac{\lambda_3}{\mu^3} \right); C_4 = \hbar^3 \left(-\frac{\lambda_4}{\mu^4} + \frac{3\lambda_3^2}{\mu^5} \right)$$

- We obtain: $\mu = 1, \lambda_3 = 1, \lambda_4 = 1$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

Now, using these experimental values and using the expressions for C_2 , C_3 and C_4 at lowest level in \hbar what we get is μ is equal to 1, λ_3 is equal to 1, λ_4 is equal to 1. This is what we obtain from the equations that are there in the blue box and we get the results that are there in your green box at the bottom of the slide.

(Refer Slide Time: 06:00)

• If this were all, we could then compute the connected Green's functions. This “naïve” treatment would give the following results up to two loops:

o

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

Now, what we are do is if we use these results; if we use these results and we work out the values of C_1 , C_2 , and so, at two level two loop level what we get is the results that are shown in your slide, in this slide.

(Refer Slide Time: 06:02)

$$\begin{aligned}C_1^{naive} &= -\frac{1}{2}\hbar + \frac{1}{24}\hbar^2 + O(\hbar^3); C_2^{naive} = \hbar + \frac{1}{2}\hbar^2 - \frac{3}{4}\hbar^3 + O(\hbar^4) \\C_3^{naive} &= -\hbar^2 - \frac{1}{2}\hbar^3 - \frac{131}{24}\hbar^4 + O(\hbar^5) \\C_4^{naive} &= 2\hbar^3 - 2\hbar^4 - \frac{147}{4}\hbar^5 + O(\hbar^6) \\C_5^{naive} &= -5\hbar^4 + \frac{61}{2}\hbar^5 + \frac{5665}{24}\hbar^6 + O(\hbar^7) \\C_6^{naive} &= 10\hbar^5 - 295\hbar^6 - \frac{5105}{4}\hbar^7 + O(\hbar^8) \\C_7^{naive} &= 35\hbar^6 - \frac{5195}{2}\hbar^7 - \frac{47075}{24}\hbar^8 + O(\hbar^9)\end{aligned}$$

NPTEL ONLINE
CERTIFICATION COURSE

14

In other words, using the one loop value, these are one loop values the values given at the in the green box or one loop values, one loop perturbation values and if we use this values and we work out the connected functions at two loop levels we get these results.

Now, it is very clear from these results that the values of C 2, C 3 and C 4 that we that is given in this slide do not coincide with the value that were observed experimentally. You can clearly see here C 2, C 3 and C 4 here on this slide, and C 2, C 3 and 4 here at the top of the slide they do not coincide.

(Refer Slide Time: 07:10)

• However, we see that now $C_{2,3,4} = C_{2,3,4}^{exp}$ no longer hold, and therefore we must re-tune the parameters order by order in perturbation theory.

• In the present case, we need up to two-loop accuracy:

$$\mu = 1 + \frac{1}{2}\hbar + \hbar^2 + O(\hbar^3); \quad \lambda_3 = 1 + \hbar - \frac{49}{24}\hbar^2 + O(\hbar^3)$$
$$\lambda_4 = 1 - \frac{3}{2}\hbar + \frac{5}{4}\hbar^2 + O(\hbar^3)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

So, what we do is we need to revert back to C_2 , C_3 and C_4 , we need to rework them at the two loop level when we rework them at two loop level and then workout the values of μ , λ_3 and λ_4 , the values that we get is given at the bottom of the slide.

Let me repeat and C_2 , C_3 and C_4 values we had obtained at the one loop level and those were the values that we saw here, here in the green box. These were the one loop values. But we then estimated using this one loop values we estimated the Green functions at the two loop level. And we found that C_2 , C_3 and C_4 do not coincide with the experimental results as is to be expected.

Therefore, we would revisited C_2 , C_3 and C_4 , we worked out the C_2 , C_3 and C_4 are the two loop level. Using the revised working of C_2 , C_3 and C_4 at the two loop level we

rework the parameters at the two loop level that is we rework mu lambda 3 and sigma 4 at the two loop level, and then we use these expression to work out C 1, C 2, C 3 and so on.

(Refer Slide Time: 08:33)

- The renormalized connected Green's functions, suitably truncated to the correct order in \hbar , read:
$$C_1 = -\frac{1}{2}\hbar + \frac{1}{24}\hbar^2 + O(\hbar^3); C_2 = \hbar$$
$$C_3 = -\hbar^2; C_4 = 2\hbar^3; C_5 = -5\hbar^4 + 3\hbar^5 - \frac{5}{2}\hbar^6 + O(\hbar^7)$$
$$C_6 = 10\hbar^5 - 45\hbar^6 + 90\hbar^7 + O(\hbar^8)$$
$$C_9 = 35\hbar^6 + 480\hbar^7 - 2065\hbar^8 + O(\hbar^9)$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 16

And we find now that C 2, C 3 and C 4 do coincide with the experimental result that is one part of the story.

(Refer Slide Time: 08:48)

IMPORTANT OBSERVATIONS

- $C_{2,3,4}$ are completely free of higher-order corrections.

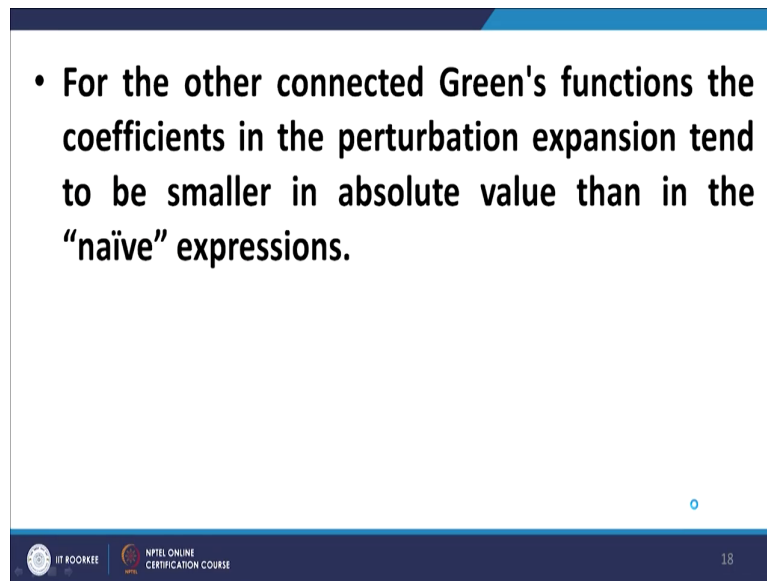

IIT ROORKEE

(Refer Slide Time: 08:51)

A presentation slide with a white background and a blue header and footer. The main content is a single bullet point. The footer contains logos for IIT Roorkee and NPTEL Online Certification Course, along with the slide number 18.

- For the other connected Green's functions the coefficients in the perturbation expansion tend to be smaller in absolute value than in the “naïve” expressions.

The second part of this story is in that if you look at this if you look at the relative values, the naive values naive values that we use without renormalization and the values that we used with renormalization you find that the differences have are much less in the case of renormalization compare vis-à-vis, the values that are worked out on the naive basis.

(Refer Slide Time: 08:52)

$C_1^{naive} = -\frac{1}{2}\hbar + \frac{1}{24}\hbar^2 + O(\hbar^3)$	NAIVE	$C_1 = -\frac{1}{2}\hbar + \frac{1}{24}\hbar^2 + O(\hbar^3)$
$C_2^{naive} = \hbar + \frac{1}{2}\hbar^2 - \frac{3}{4}\hbar^3 + O(\hbar^4)$		$C_2 = \hbar$
$C_3^{naive} = -\hbar^2 - \frac{1}{2}\hbar^3 - \frac{131}{24}\hbar^4 + O(\hbar^5)$		$C_3 = -\hbar^2$
$C_4^{naive} = 2\hbar^3 - 2\hbar^4 - \frac{147}{4}\hbar^5 + O(\hbar^6)$		$C_4 = 2\hbar^3$
$C_5^{naive} = -5\hbar^4 + \frac{61}{2}\hbar^5 + \frac{5665}{24}\hbar^6 + O(\hbar^7)$		$C_5 = -5\hbar^4 + 3\hbar^5 - \frac{5}{2}\hbar^6 + O(\hbar^7)$
$C_6^{naive} = 10\hbar^5 - 295\hbar^6 - \frac{5105}{4}\hbar^7 + O(\hbar^8)$		$C_6 = 10\hbar^5 - 45\hbar^6 + 90\hbar^7 + O(\hbar^8)$
$C_7^{naive} = 35\hbar^6 - \frac{5195}{2}\hbar^7 - \frac{47075}{24}\hbar^8 + O(\hbar^9)$		$C_7 = 35\hbar^6 + 480\hbar^7 - 2065\hbar^8 + O(\hbar^9)$

RENORMALIZED

So, that is an important, this is an important topic. This of course, would be carried on towards the when we talk about field theory in Minkowski space but fundament at the conceptual level this is what renormalization is all about. We now talk about loop divergences.

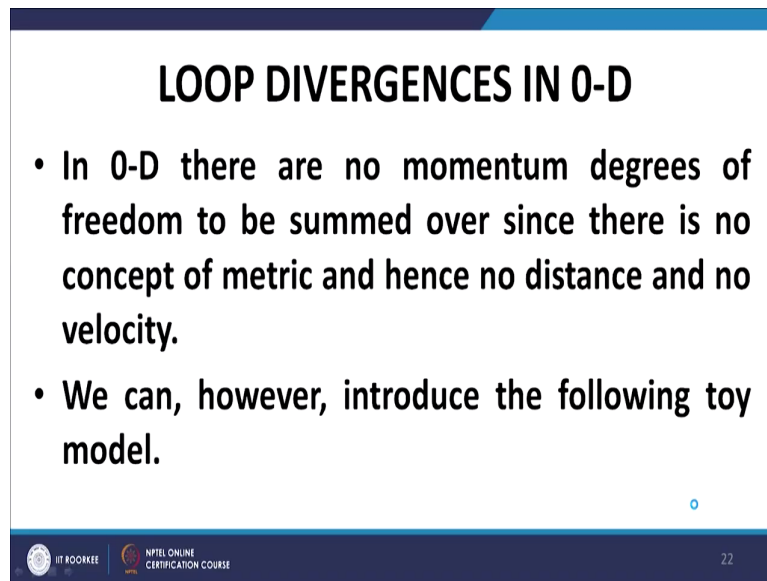

(Refer Slide Time: 09:41)

- In nontrivial theories, loop diagrams often contain infinities makes the need to do something about them all the more urgent.
- **Loop divergences arise from summation over internal degrees of freedom of Feynman diagrams.**
- In zero dimensions there are no such internal degrees of freedom, and all diagrams are finite.

Now, where do, what do we mean by loop divergences? Feynman diagrams for certain field theories or certain types of actions contain diagrams which take the form of loops. These loops arise from summation over internal degrees of freedom in the in these diagrams. When the when the summation is to be done over internal degrees of freedom for example, internal momentum and the integration is to be done from 0 to infinity, divergences may arise.

(Refer Slide Time: 10:19)

LOOP DIVERGENCES IN 0-D

- In 0-D there are no momentum degrees of freedom to be summed over since there is no concept of metric and hence no distance and no velocity.
- We can, however, introduce the following toy model.

o

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 22

Although, in the case of 0 level, 0-dimensional field theory the concept of loop divergences is redundant because there is no concept of momentum as such, there is no concept of a metric, no concept of a distance and no concept of velocity. And therefore, there is no concept of momentum and as a result of which loop divergence is do not exists in 0-dimensional field theory. But, by way of illustrating the phenomenon we introduce certain new features into our into our ϕ^4 theory.

(Refer Slide Time: 10:41)

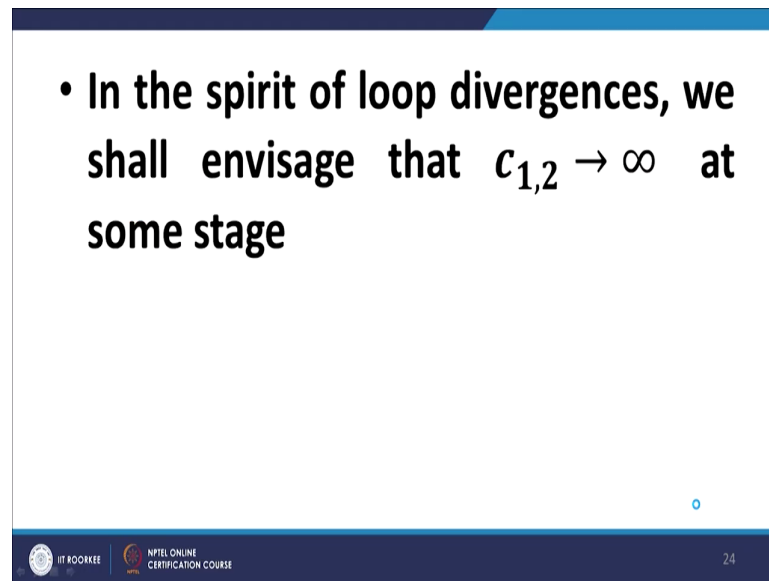

- Consider the φ^4 theory.
- Let us introduce yet another Feynman rule:
 - we shall apply a factor $1 + c_1$ to every closed loop that contains precisely one vertex, and
 - a factor $1 + c_2$ to every closed loop that contains precisely two vertices.
 - Loops with more vertices remain unaffected.

o

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 23

We introduced new rule two new Feynman rules. We apply a factor of $1 + c_1$ to every closed loop that contains precisely one vertex, and we apply a factor of $1 + c_2$ to every closed loop that contains precisely two vertices. Loop with more vertices remain unaffected. So, these are two rules that we add to the existing refer to of rules to externally introduced the concept of loop divergence in our φ^4 theory in 0-dimensional space time because a priori in 0-dimensional space time loop divergences would not exist.

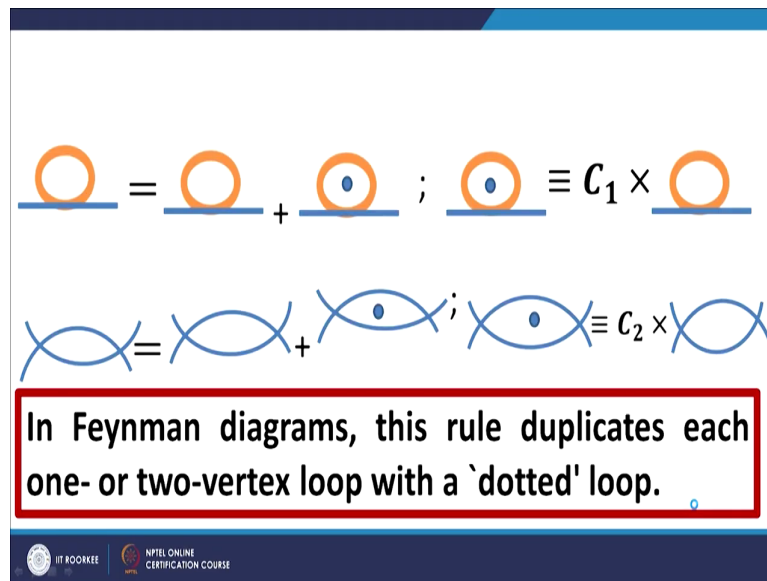

(Refer Slide Time: 11:44)

A presentation slide with a white background and a blue header and footer. The main content is a single bullet point in bold black text. The footer contains logos for IIT Roorkee and NPTEL Online Certification Course, along with the slide number 24.

- In the spirit of loop divergences, we shall envisage that $c_{1,2} \rightarrow \infty$ at some stage

And we will then later on we will make C_1 and C_2 approach infinity to explore the implications of loop divergences.

(Refer Slide Time: 11:56)

Diagrammatically in terms of a Feynman diagrams the two rules translate to this to what is shown in your figure in this figure, if you have a loop with one vertex that is the upper diagram it translates to a loop and a dotted loop, where a dotted loop is C_1 into the original loop.

Similarly, if you have a loop with two vertices and the it translates to a loop with two vertices and a dotted loop with two vertices, the dotted loop with two vertices is nothing, but C_2 into the original loop. Recall that in due course C_1 and C_2 would be made to approach infinity.

(Refer Slide Time: 12:43)

- The Feynman diagrams are governed by the Schwinger-Dyson equation. Our new rule must therefore be implemented into a modified SDE.

The necessary new ingredients are made up out of those Feynman diagrams that contain only dotted loops.

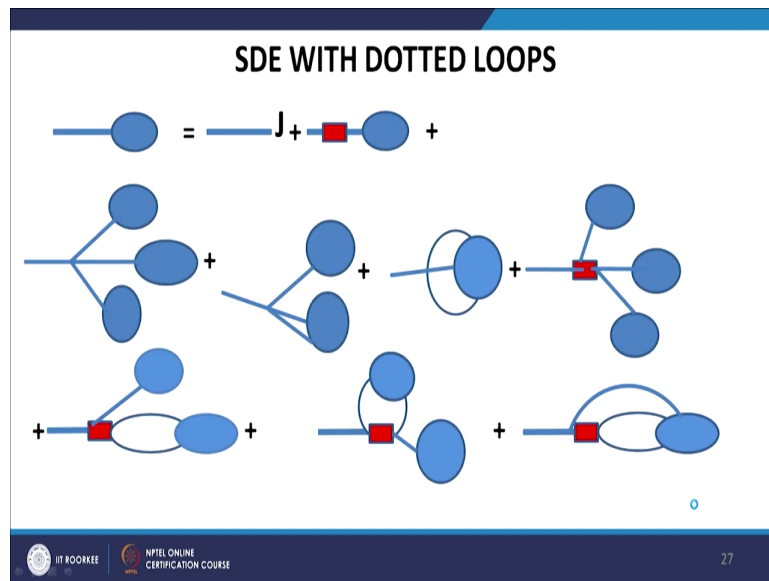

- We can now rewrite the appropriate SDE for our φ^4 theory with the added dotting rule:

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 26

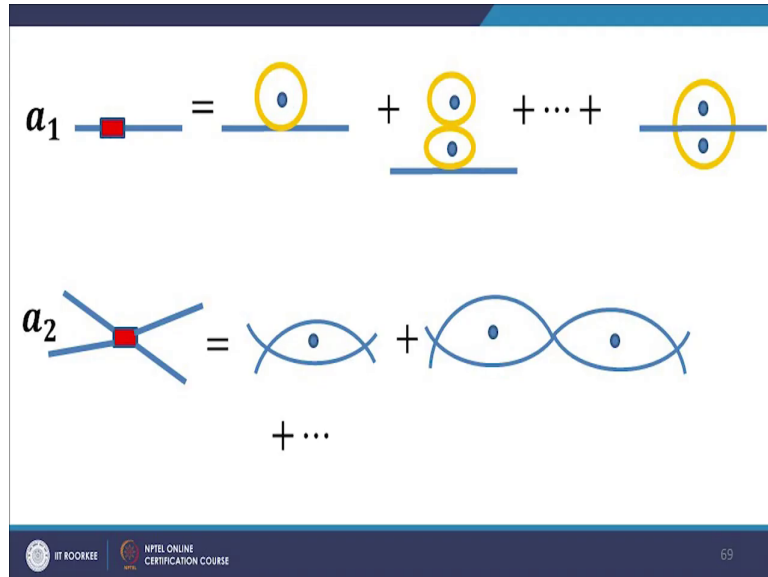

Now, we will look at the Schwinger Dyson equation. Having introduced the new Feynman rules to take cognizance of the possibility of loop divergences we introduced this Schwinger Dyson equations. Let us write down the set of Feynman diagrams, and then write down the Schwinger Dyson equation on the basis of those diagrams.

(Refer Slide Time: 13:03)

The with the introduction of dotted loops the Feynman diagrams red face and the red coloured boxes figures or figures with red coloured boxes or the new additions to the to the Feynman diagrams. And these are mandated by the introduction of dotted loops. Let us look at the definition of these red coloured boxes.

(Refer Slide Time: 13:36)

The red coloured boxes with two lines represent a single vertex with a with the dotted loop in this form which is given here. This is nothing, but C 1 into the original loop, this is C 1, C 2 in original loop, then we will have C 1, C 2 square into the origin and so on, and this diagram is the extra diagram here. And if we have a box with 4 vertices, this is equal to the two what two vertices dotted diagram and then the two vertice dotted diagram in parallel, and then 3 and so on. So, this is how we define the boxes that are shown here.

And we let us call this a 1 and let us call it a 2. And the upper box is the upper diagram on the left hand side let us call it a 1 the lower diagram on the left hand side let us call it a 2. Then, making use of this set of Feynman diagrams and we can write down the Schwinger Dyson equation including these loops in the form of this expression.

(Refer Slide Time: 14:54)

- $\phi = \frac{J}{\mu} - \frac{a_1}{\mu} \phi$
- $\frac{\lambda_4}{6\mu} \phi^3 - \frac{\hbar\lambda_4}{2\mu} \phi\phi' - \frac{\hbar^2\lambda_4}{6\mu} \phi''$
- $\frac{a_2}{2\mu} \phi^3 - \frac{\hbar a_2}{2\mu} \phi\phi' - \frac{\hbar a_2}{\mu} \phi\phi' - \frac{\hbar^2 a_2}{2\mu} \phi''$
- OR
- $(\mu + a_1)\phi = J - (\lambda_4 + 3a_2)(\phi^3 + 3\hbar\phi\phi' + \hbar^2\phi'')$

**SDE EQUATION FOR
DOTTED ACTION
(ϕ^4 THEORY)**

29

This is the Schwinger Dyson equation for the phi 4 theory including the various loops and it can be written simplified and written in the form which is given in the lower equation, the bottom equation here.

The upper equation corresponds to a up diagram wise evaluation of each diagram. For example, the first diagram here is evaluate evaluated as J upon mu. The second diagram if you note is evaluated as minus a 1 upon mu into phi. And this part is phi, the this loop is phi, the box here is minus a 1 and we have one line, so we have 1 upon mu; so, 1 upon mu, a 1 into phi.

And that is in that is the way the evaluation is done for all the other diagrams here. And this whole equation can be written simply in a simplified manner in the second equation that is given at the bottom of your slide.

(Refer Slide Time: 16:04)

- $\phi = \frac{J}{\mu} - \frac{B_1}{\mu} - \frac{B_2}{\mu} \phi - \frac{\lambda_3}{2\mu} \phi^2 - \frac{\hbar\lambda_3}{2\mu} \phi'$
- $-\frac{B_3}{2\mu} \phi^2 - \frac{B_3}{\mu} \phi^2 - \frac{\hbar B_3}{2\mu} \phi' - \frac{\hbar B_3}{\mu} \phi'$
- $\frac{\lambda_4}{6\mu} \phi^3 - \frac{\hbar\lambda_4}{2\mu} \phi\phi' - \frac{\hbar^2\lambda_4}{6\mu} \phi''$
- $\frac{B_4}{2\mu} \phi^3 - \frac{\hbar B_4}{2\mu} \phi\phi' - \frac{\hbar B_4}{\mu} \phi\phi' - \frac{\hbar^2 B_4}{2\mu} \phi''$
- **OR**
- $(\mu + B_2)\phi = (J - B_1) - (\lambda_3 + 3B_3)(\phi^2 + \hbar\phi') - (\lambda_4 + 3B_4)(\phi^3 + 3\hbar\phi\phi' + \hbar^2\phi'')$

**SDE
EQUATION
FOR
DOTTED
ACTION
($\phi^{3/4}$)**

30

For the phi 3 4 theory the equation becomes a little bit more involved. It is the form that is given on this slide.

(Refer Slide Time: 16:13)

RENORMALIZED ACTION

- **Undotted action:**
- $S(\varphi) = \frac{1}{2}\mu\varphi^2 + \frac{1}{24}\lambda_4\varphi^4$
- **Dotted (Renormalized Action):**
- $S(\varphi) = \frac{1}{2}(\mu + a_1)\varphi^2 + \frac{1}{24}(\lambda_4 + 3a_2)\varphi^4$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 31

Now, if you look at the action that corresponds to the Feynman diagrams that include the dotted diagram, that in other words that include the red boxes. Then, the dotted renormalized action takes the form of the bottom equation, the equation that is given below.

This is the this was the original equation, the upper equation was the original equation and the bottom equation is the renormalized equation action, renormalized action, the upper action is the original action as you can very well fine see. And the bottom action is the renormalized action which gives rise to this particular Schwinger Dyson equation, the bottom Schwinger Dyson equation.

Now, the it is a very interesting observation here. In this action if you look at it the bare parameters of the action that is mu and lambda 4 these were the bare pair parameters as you can see from the upper expression for the action. These were the original parameter. They do

not appear alone anywhere. In the action because they appear in the action itself together with a_1 μ appears with a_1 and λ_4 appears with $3 a_2$.

So, it follows as a corollary that wherever in whether it be an experimental measurement or be it be a theoretical computation of any level or any computation of Green functions are connected green function or any other any other parameter or any other attribute of the theory these two expressions will appear as one unit, as a complete unit. μ plus, μ will always appear with a_1 , and λ_4 will always appear with $3 a_2$, if we take account of the loop divergences represented by the dotted in diagrams.

Well, there is another fallout of this. The fallout is that, if now if now C_1 and C_2 and are allowed to approach infinity or allowed to move infinity representing divergences, then obviously, a_1 and a_2 approach infinity a_1 and a_2 also tend to infinity. So, in some sense it would trigger a reaction that, the action becomes unbounded and therefore, the theory fails.

But what recovers the theory or what saves the theory if the fact that we can have μ also, the bare parameters also infinite and as such the infinities could very well cancel each other. And if the infinities cancel each other then we are left with finite quantities and therefore, the action becomes finite at every level and all computations arising from the action, in fact, the theory itself becomes a finite and viable theory.

So, in a sense this enables us the fact that μ and a_1 λ_4 and $3 a_2$ occur in pairs invariably essentially enables us to do a kind of renormalization to get out of a situation where the loops become a_1 and a_2 , the collection of loops represented by a_1 and a_2 show divergent behavior, right.

(Refer Slide Time: 20:02)

The slide features a dark blue header bar at the top. The main content area is white with the text "SCALE DEPENDENCE" centered in a bold, black, sans-serif font. A small blue circle is positioned in the bottom right corner of the white area. The footer is a dark blue bar containing the IIT Roorkee logo on the left, the NPTEL Online Certification Course logo in the center, and the number "34" on the right.

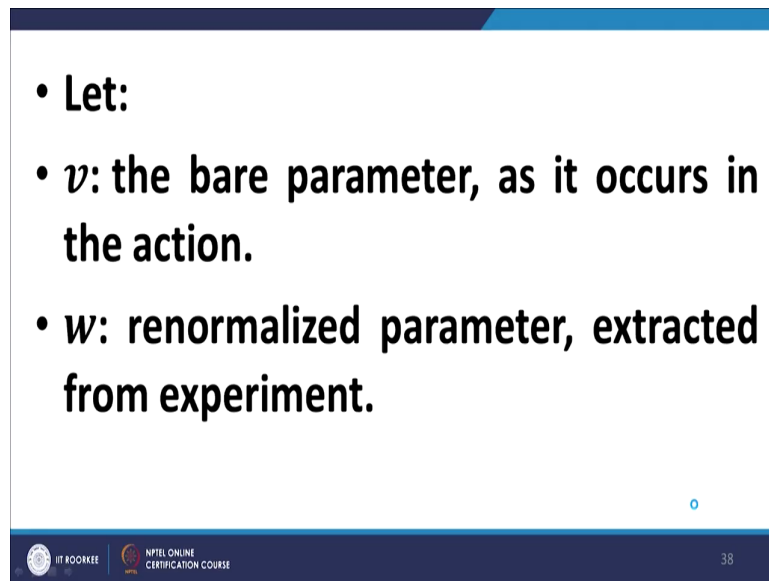

(Refer Slide Time: 20:04)

1. The parameters of the action have to be determined by comparison to **experimentally measured quantities**.
 2. Such measurement experiments do not take place in some abstract realm, **but rather in a concrete physical situation**.
 3. The **efficacy of the experimental apparatus** partially contributes to the measurement result.
- 

Now, let us let us explore the concept of renormalization a bit further. Now, we look at the issues scale dependence. When we when I talk about scale dependence, I am essentially talking about the various factors that influence the measurement experimental measurement of the Green functions or the connected Green functions. This is the fundamental thing is that these quantities are usually measured by scattering experiments.

Now, scattering experiments or the outcome of scattering experiments really depends on the on the energy scales at which the experiment experimental apparatus is able to operate. And therefore, it becomes relevant to explore the impact of such factor as the level as the energies involved in this scattering experiments on the measured quantities of attributes or parameters of the theory. So, that is the next exercise, right.

(Refer Slide Time: 21:11)

• **Let:**

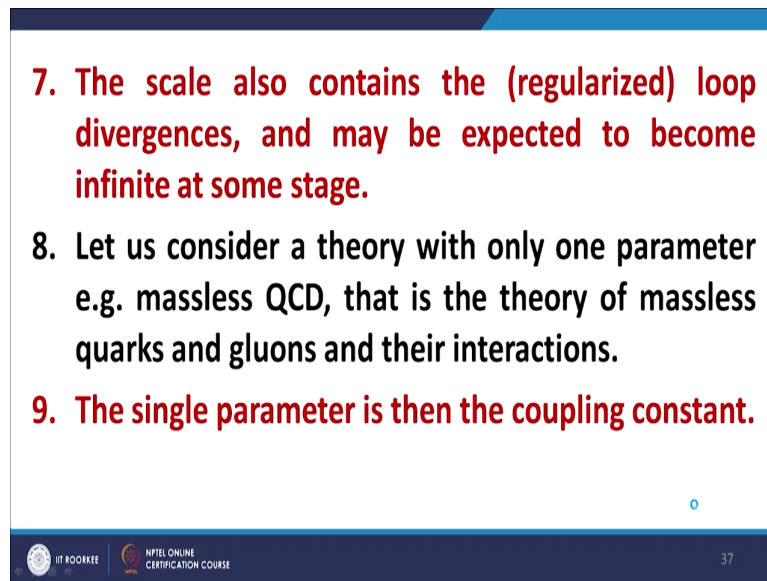

- v : the bare parameter, as it occurs in the action.
- w : renormalized parameter, extracted from experiment.

o

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 38

So, let v with the bare parameter as it occurs in the action, v is the original parameter that occurs in the action.

(Refer Slide Time: 21:24)

7. The scale also contains the (regularized) loop divergences, and may be expected to become infinite at some stage.

8. Let us consider a theory with only one parameter e.g. massless QCD, that is the theory of massless quarks and gluons and their interactions.

9. The single parameter is then the coupling constant.

o

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 37

We were now for the moment we are confining ourselves to an a theory with only one parameter. For example, it could be a massless quarks and gluons theory with their interaction. So, there is only one parameter there is no mass term and there is only one parameter that that is involved in the action that we call v . v is the bare parameter, w is the renormalized parameter which is extracted from the experiment. Repeat, v is the bare parameter as it occurs in the action and w is the renormalize parameter extracted from the experiments.

(Refer Slide Time: 21:58)

- **The renormalized coupling w is then a function of the bare coupling v and the experimental scale, embodied by the scale s :**
- $w = F(s; v)$ (1)
- This relation ought to be **invertible**, so that we can find v given w :
- $v = G(s; w)$ (2)
- Obviously we have
- $w = F(s; G(s; w)), v = G(s; F(s; v))$ (3)

  39

Now, the renormalized parameter, renormalized coupling or the renormalized parameter would be a function of not only the original parameter the bare parameter v , but also the scale of energy or such similar factors that we are clubbing together as a scale. So, it they it would be a function number 1, of v which is the bare parameter the true parameter of the theory and number 2, as the scale of operation of the operators by which this determination is taking place. So, we can write w as a function of s and v .

Now, we need this relation to be invertible because we want to be able to determine the bare parameter out of the renormalized outcomes or the renormalized computations or the renormalized observations. And therefore, we must have v is equal to G s and, or G G of s and w which enables us using 1 and 2, we can simply write equation number 3.

(Refer Slide Time: 23:10)

- **By differentiation we find the following relations between the derivatives of F and G :**
- $\frac{\partial F}{\partial v} \frac{\partial G}{\partial w} = \frac{\partial w}{\partial v} \frac{\partial v}{\partial w} = 1$ or $F_1 G_1 = 1$ (4)
- $F_0 + F_1 G_0 = 0$ (5)
- **where the subscript 0 denotes partial derivatives with respect to s , and the subscript 1 stands for a partial derivative with respect to the other argument.**

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 40

Now, by differentiating by differentiating these two expressions, equation number 1 and equation number 2 we can arrive at these two fundamental results. $F_1 G_1$ is equal to 1, F_0 plus $F_1 G_0$ is equal to 0, where the suffix 0 relates to differentiating with respect to s , and 1 represents to differentiation with respect to the other parameter, other independent variable that the F and G depend on. For example, F depends on two parameters s and v . So, when I write F_1 it is the derivative of F with respect to v and when I write F_0 it is a derivative of F with respect to s .

(Refer Slide Time: 24:09)

- **Furthermore, we can always choose the scale such that the bare and renormalized couplings coincide at vanishing scale:**
- $F(0; v) = v$ (6)
- **Since the (actual) bare (and possibly infinite) parameter v must be independent of the scale, the renormalized parameters measured at different scales must be related to each other.**

  41

Now, with we can choose the scale such that the bare and renormalized couplings coincide when the scale is 0. In other words, we can define our scale in such a way, define s in such a way that at s equal to 0 the renormalized and the renormalized value v and the bare value renormalize value w I am sorry; renormalize value w and the bare value v coincide.

Let me repeat we can choose the s equal to 0 at that point, at that scale at which the bare value or the bare parameter v equals the renormalized parameter or the value of the parameter through renormalization that is w . So, I can write $F(0; v)$ is equal to v , because remember $F(s; v)$ is equal to w if you recall, $F(s; v)$ was equal to w . We are defining the 0 of s such a way that at s equal to 0, w is equal to v .

(Refer Slide Time: 25:29)

- *We shall now investigate this relationship between renormalized parameters measured at different scales.*
- **Under an infinitesimal change of scale, the renormalized coupling must change as**
- $$\frac{d}{ds} W = \frac{dF(s;v)}{ds} = \frac{dF(s;G(s;w))}{ds},$$
- **where in the last form all reference to the infinite v has disappeared.**

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 42

Now, we investigate the relationship between the renormalized parameters that is w and the various scale that is the energy scales or such other scales. So, under an infinitesimal change of scale the renormalized coupling will change as $\frac{d}{ds} w$ by ds , $\frac{d}{ds} w$ by ds is given by this expression, and w is nothing but $F(s;v)$ and that is nothing but this expression where I have substituted a v equal to $G(s;w)$.

So, interestingly if you look at this expression, the first and third equations, the first and third terms there is no mention of the parameter v at all here. There is absolutely no mention of the parameter v . Recall that the parameter v could also take infinite values in view of the concept of renormalization that I had explained just a few minutes back.

(Refer Slide Time: 26:21)

- The scale s itself, however, could also be also infinite.
- The scale-dependence of w is therefore only sensible if the last term $\frac{dF(s;G(s;w))}{ds}$ is actually independent of s , that is,

$$\frac{\partial}{\partial s} \left(\frac{d}{ds} W \right) = \frac{\partial}{\partial s} \left(\frac{dF(s;G(s;w))}{ds} \right)$$

$$= \frac{\partial}{\partial v} \left(\frac{\partial F(s;G(s;w))}{\partial s} \right) \frac{\partial v}{\partial s} + \frac{\partial^2 F(s;G(s;w))}{\partial s^2} = F_{01} G_0 + F_{00} = 0 .$$

o

43

Now, however, the scale itself can become infinite and therefore, this expression $d w$ upon ds can have a meaningful or a sensible value or a logical value only if the derivative with respect to s or this expression $d w$ by ds is independent of s , because s can take values up to infinity. So, that being the case we must require that the derivative of w with respect to s must be independent of s .

Now, if you simplify this expression, if you simplify this expression what we get is F_{01} , G_0 plus F_{00} is equal to 0. There is quite obvious straightforward steps in simplification, nothing else. Simply taking the total derivative as the expanding the total derivative that is it and we get F_{01} , G_0 , F_{00} . Recall F_{00} is the is the second derivative of F with respect to s , F_{01} is the derivative of F with respect to s and with respect to v , and G_0 is the derivative of G with respect to s .

(Refer Slide Time: 28:00)

- Hence, we have:
- $F_{01}G_0 + F_{00} = 0$. Also, from above:
- $F_0 + F_1G_0 = 0$. Thus,
- $F_{00} - \frac{F_0F_{01}}{F_1} = 0$.
- Dividing by F_1 we can see that the requirement becomes:
- $\frac{\partial}{\partial s} \left(\frac{F_0(s;v)}{F_1(s;v)} \right) = 0$ or $\frac{\partial}{\partial s} \left(\frac{\partial F / \partial s}{\partial F / \partial v} \right) = 0$.

  44

Hence, we have two equations $F_{01}G_0 + F_{00} = 0$ and $F_0 + F_1G_0 = 0$. Using these two equations for substituting for G_0 from equation the second equation in equation 1, I get the equation in the blue box. If I divide throughout by F_1 I can write this equation in the form that is given at the bottom of your slide. The first equation at the bottom of your slide which simplifies to the second equation, that is the equation given in the green box at the bottom of your slide.

(Refer Slide Time: 28:40)

- From above $\frac{\partial}{\partial s} \left(\frac{F_0(s;v)}{F_1(s;v)} \right) = 0$ or $\frac{\partial}{\partial s} \left(\frac{\partial F / \partial s}{\partial F / \partial v} \right) = 0$
- There must therefore be a function $\beta(v)$ of v only, such that

$$\frac{\partial}{\partial s} F(s;v) = \beta(v) \frac{\partial}{\partial v} F(s;v)$$

- By separation of variables we can solve this equation, to find \mathcal{F}

$$F(s;v) = \mathcal{F}(s + h(v)), h(v) = \int \frac{dv}{\beta(v)}.$$

  45

Now, from this expression we find from this expression if you look at it carefully del by d by ds, dF by ds, dF by dv is equal to 0. That means, what? That means, dF by ds is equal to some constant into dF by dv, some dF by ds is equal to some function of v into dF by dv. dF by ds is equal to some function of v into dF by dv. So, I can write it as this way dF by ds is equal to beta of v, beta of v some function of v into dv by d; dF by dv.

By separation of variables we can solve this equation and we find that F s, v can be written in the form of F script s plus h v, where h v is a new function which is obtained by this expression integral of dv upon beta v.

(Refer Slide Time: 29:48)

- We must have $w = v$ if $s = 0$, and therefore \mathcal{F} and h must be each other's inverse because:
- $v = w = F(0, v) = \mathcal{F}(h(v)) = v$
- This in its turn implies that:
- $w = \mathcal{F}(h(w))$. Also:
- $w = F(s, v) = \mathcal{F}(s + h(v))$. Hence,
- $h(w) = s + h(v)$.

IT ROKKEE NPTEL ONLINE CERTIFICATION COURSE 46

Now, w is recall, w is equal to v if s is equal to 0. By the definition of s, by the definition of our scale we have defined our scale in such a way that at s is equal to 0, w is equal to v. Therefore, what happens? v is equal to w is equal to F 0 v we have already shown that, is equal to F h of v because s is equal to 0 here. If I put h equal to 0, I get this F 0 v which is nothing but v, which is nothing but w. So, v is equal to w is equal to F 0 v is equal to F F script, s is 0, so F script h v.

And from this what do I infer? I infer from v is equal to F h v, that F and h are inverses of each other, and F and h are inverses of each other. And if h and F and h are inverses of each other, we automatically have w is equal to F of h v. And w, but w is also equal to F h v that is equal to F s plus h v. Now, from these two equations w is equal to F F script h v and w is equal to s

script s plus h I am sorry, I am sorry; w is equal to F script h w and w is equal to s script s plus h v , that implies that h w must be equal to s plus h v .

(Refer Slide Time: 31:30)

- Now we can take the derivative with respect to s :
- $\frac{d}{ds} w = \frac{\partial}{\partial s} F(s; v) = \mathcal{F}'(s + h(v)) = \mathcal{F}'(h(w)) = \frac{1}{h'(w)}$

since

- $\mathcal{F}'(h(w))h'(w) = \frac{\partial \mathcal{F}(h(w))}{\partial w} = \frac{\partial w}{\partial w} = 1$

47

So, now we take the derivative with respect to s we get the d by ds of half w , d by d as of w is equal to d by ds of F s v that is equal to F s plus h v , that is equal to that is equal to F dash F script dash s plus h v that is equal to F script dash h w that is equal to 1 upon h dash w . This is quite obvious because w is nothing but s plus h v , it is here. Just a minute, yes is here; h w is equal to s plus h v . So, h w is nothing but s plus h v , so I have put this here.

And then I have this is nothing but yeah F s v is equal to F script s plus h v , F h v is equal to, F script s plus h v the derivative takes the derivative here. And then we have s plus h v is equal to h w , so this becomes here and this is equal to 1 upon h dash w . Why is this shown in the

expression on the red box? That $F \dashv h w$, $h \dashv w$ is equal to 1 that is that is why $F \dashv s$ w is equal to 1 upon $s \dashv w$.

(Refer Slide Time: 33:01)

- So that we finally arrive at the scale-dependence of w using:

- $\frac{d}{ds} w = \frac{1}{h'(w)}$ and $h(v) = \int \frac{dv}{\beta(v)}$ as:
- $\frac{d}{ds} w(s) = \beta(w)$

48

So, we finally, arrived at the scale dependence $d w$ by ds is equal to 1 upon $s \dashv w$ and, but $h v$ is equal $\int dv$ upon βv and therefore, therefore, $h \dashv w$ is nothing but βw . When you differentiate $h v$ is equal to this expression you differentiate and put v equal to w , what we get is βw . So, d by ds is equal to $w s$, is equal to d by ds $w s$ is equal to βw .

(Refer Slide Time: 33:40)

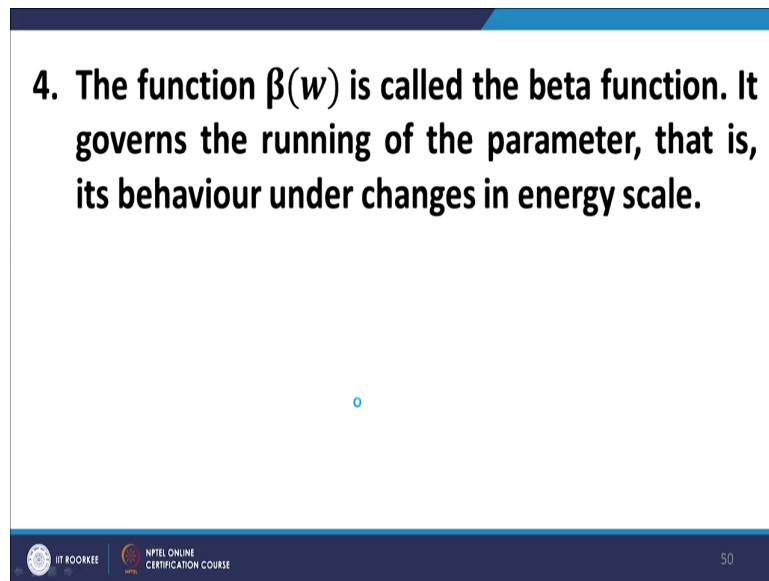

IMPORTANT FEATURES

1. All reference to the bare coupling has been removed.
2. The renormalized coupling has a definite, predictable dependence on the energy scale of the measuring experiment.
3. The equation: $\frac{d}{ds} w(s) = \beta(w)$ is called the renormalization group equation, the group operation in this case being the shift in scale.

NPTEL ONLINE
CERTIFICATION COURSE49

So, all reference to the bare coupling has been removed number 1. The renormalized coupling has a definite predictable dependence on a energy scale of the measuring experiment that is given by beta w. The equation d by ds, w s is equal to beta w is called the renormalization group equation. And the group parameter is the shift in the scale, the group parameter or the group operation is the shift in the scale. So, I repeat the equation d by ds w, as is equal to beta w is called the renormalization group equation and the group operation is the shift in the scale. So, this is important.

(Refer Slide Time: 34:27)

4. The function $\beta(w)$ is called the beta function. It governs the running of the parameter, that is, its behaviour under changes in energy scale.

o

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 50

And beta w is the beta function which governs the running of the parameter that is the behaviour under changes of the energy scale.

Thank you.
