Lecture – 39
Field Theory in 1-D (1)

Welcome back. So, in the last lecture we concluded our discussion of the Field Theory in zero-dimensional space time. Today, I propose to extend the framework to one-dimensional lattice, move onto the continuum version of the one-dimensional framework. And then, we will graduate on to the Minkowski space in the next few lectures.

(Refer Slide Time: 00:48)

RECAP-0-D FIELD THEORY

- ACTION
- GREEN'S FUNCTIONS (MOMENTS) AND THE PATH INTEGRAL
- CONNECTED GREEN'S FUNCTIONS (CUMULANTS)
- THE FREE THEORY
- ϕ^4 MODEL AND PERTURBATION THEORY

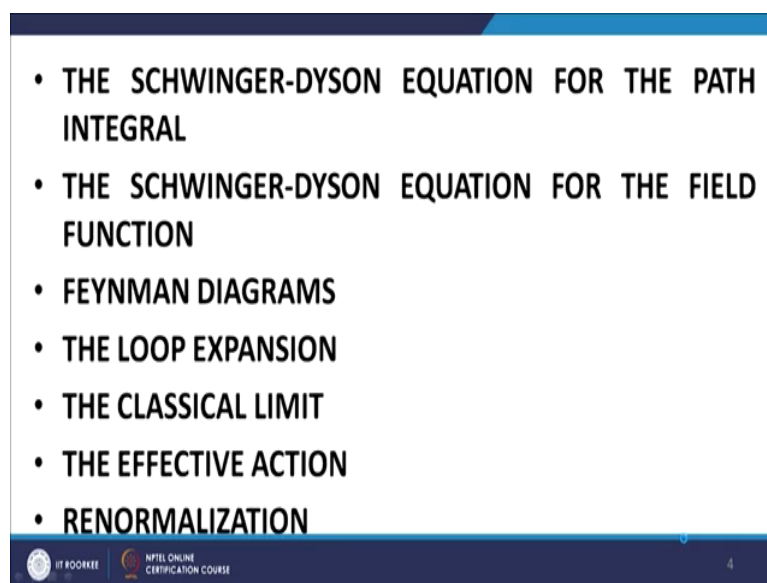

IT Roorkee NPTEL ONLINE CERTIFICATION COURSE 3

But, before we get into the nitty-gritty, a brief recap on where we stand at the moment. As far as zero-dimensional field theory was concerned we started with the action, we defined the

Green's functions and the connected Green's functions for the theory. And we evaluated the relevant Green functions for the free theory.

We then introduced, in the interactions through the ϕ^4 model by adding a term to the action, and developed this as a perturbation expansion, perturbation theory in powers of the coupling parameter coupling constant.

(Refer Slide Time: 01:25)

And, we also arrived at the Schwinger-Dyson Equation for the path integral we defined the generating functional for the theory and we arrived at the Schwinger-Dyson equation or the evolution equation for the path integral or the generating functional.

We also arrived at the Schwinger-Dyson equation for the field functions. Then, we moved on to the concept of Feynman diagrams, which perform which constitute a wonderful recipe for a

diagrammatic representation of various issues in relation to quantum field theory; they form the cornerstone of literally all field theoretic calculations. So, we introduced it Feynman diagrams at the most elementary level possible starting with the Green function for the free theory, represented by Feynman diagrams pairs of straight lines. We then moved onto the issue of loop expansion.

So, the perturbative expansions, in the context of the classified on the basis of the number of loops involved in the Feynman diagrams by introducing the parameter \hbar ; we identified \hbar with the conventional \hbar of quantum mechanics the Planck's constant.

And then, took up the issue of the classical limit of the path integral we arrived at the classical limit through the saddle point approximation. And we observed that, the behaviour of the various paths in pathways in relation to the classical trajectory which is only one of the paths.

Then we defined the effective action as the action which whose classical solution corresponds to the full quantum solution of the given action. We then, discussed renormalization in a lot of detail and that is where we concluded the last lecture.

(Refer Slide Time: 03:33)

DEFINITIONS

$$P(\varphi) = N \exp[-S[\varphi]]; N = \left[\int \exp[-S[\varphi]] d\varphi \right]^{-1}$$
$$G_n \equiv \langle \varphi^n \rangle = N \int \exp(-S[\varphi]) \varphi^n d\varphi$$
$$Z(J) = \sum_{n \geq 0} \frac{1}{n!} J^n G_n = N \int \exp(-S[\varphi] + J\varphi) d\varphi$$
$$G_n = \left[\frac{\partial^n}{(\partial J)^n} Z(J) \right]_{J=0}; W(J) = \log Z(J) \equiv \sum_{n \geq 1} \frac{1}{n!} J^n C_n$$
$$\phi(J) \equiv \frac{\partial}{\partial J} W(J) = \sum_{n \geq 0} \frac{1}{n!} J^n C_{n+1}$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 5

Just the gist of whatever has been done so far is presented in the next few slides. This first slide covers the definitions.

(Refer Slide Time: 03:40)

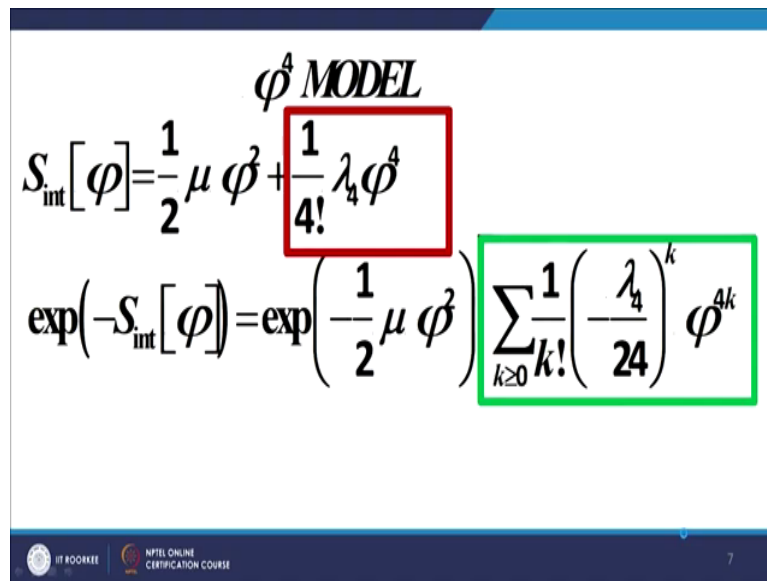

FREE FIELD

$$S_0[\varphi] = \frac{1}{2} \mu \varphi^2; N_0 = \left[\int \exp\left(-\frac{1}{2} \mu \varphi^2\right) d\varphi \right]^{-1} = \sqrt{\left(\frac{\mu}{2\pi}\right)}$$
$$P_0(\varphi) = \sqrt{\left(\frac{\mu}{2\pi}\right)} \exp\left(-\frac{1}{2} \mu \varphi^2\right)$$
$$Z_0(J) = \sum_{n=0}^{\infty} \frac{1}{n!} J^n G_n = \sqrt{\left(\frac{\mu}{2\pi}\right)} \int \exp\left(-\frac{1}{2} \mu \varphi^2 + J\varphi\right) d\varphi$$
$$= \exp\left(\frac{J^2}{2\mu}\right); W_0(J) = \frac{J^2}{2\mu}; \phi_0(J) \equiv \frac{\partial}{\partial J} W_0(J) = \frac{J}{\mu}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

(Refer Slide Time: 03:44)

ϕ^4 MODEL

$$S_{\text{int}}[\phi] = \frac{1}{2} \mu \phi^2 + \frac{1}{4!} \lambda_4 \phi^4$$
$$\exp(-S_{\text{int}}[\phi]) = \exp\left(-\frac{1}{2} \mu \phi^2\right) \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24}\right)^k \phi^{4k}$$

The free field parameters are given in this slide. Then the phi 4 model is introduced through the interaction term given in the red box and the perturbative expansion in terms of the coupling constant given in the green box.

(Refer Slide Time: 03:54)

$$Z_{\text{int}}(J) = N_{\text{int}} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24} \right)^k \int \varphi^{4k} \exp \left[-\left(\frac{1}{2} \mu \varphi^2 \right) + J\varphi \right] d\varphi$$
$$N_{\text{int}} = \left[\left(\frac{2\pi}{\mu} \right)^{1/2} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_4}{24\mu^2} \right)^k \frac{4k!}{4^k (2k)!} \right]^{-1}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

We develop the partition function or the normalization of the interaction model as a perturbative expansion, and we work out the Green functions.

(Refer Slide Time: 04:06)

$$\begin{aligned}
 G_{2n} &= N_{\text{int}} \sqrt{\left(\frac{2\pi}{\mu}\right)} \frac{1}{\mu^n} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{(4k+2n)!}{2^{2k+n}(2k+n)!} \\
 &= \frac{\frac{1}{\mu^n} \sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{(4k+2n)!}{2^{2k+n}(2k+n)!}}{\sum_{k \geq 0} \frac{1}{k!} \left(-\frac{\lambda_q}{24\mu^2}\right)^k \frac{4k!}{4^k(2k)!}} = \frac{H_{2n}}{H_0}
 \end{aligned}$$

We $2n$ point Green functions and represent them in terms of the normalization, 1 upon H_0 and the parameter or the quantity H_{2n} .

(Refer Slide Time: 04:20)

SCHWINGER DYSON EQUATION

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

(Refer Slide Time: 04:20)

SCHWINGER DYSON EQUATION FOR $Z(J)$

$$S'(\varphi)\Big|_{\varphi=\left(\frac{\partial}{\partial J}\right)} Z(J) = S'\left(\frac{\partial}{\partial J}\right) Z(J) = JZ(J)$$

FOR φ^4 FIELD

$$\mu\left(\frac{\partial}{\partial J}\right) Z(J) + \frac{1}{6}\lambda_4\left(\frac{\partial}{\partial J}\right)^3 Z(J) = JZ(J)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

We use the Schwinger-Dyson Equations for the generating functional given in the red box, and which for the φ^4 field that we have been discussing throughout takes the form given in the green box here.

(Refer Slide Time: 04:34)

SDEs FOR FIELD OPERATOR

(1): $\frac{\partial^p}{(\partial J)^p} Z(J) = Z(J) \left[\phi(J) + \frac{\partial}{\partial J} \right]^p e(J)$

(2): $S' \left(\phi + \frac{\partial}{\partial J} \right) e(J) = J$

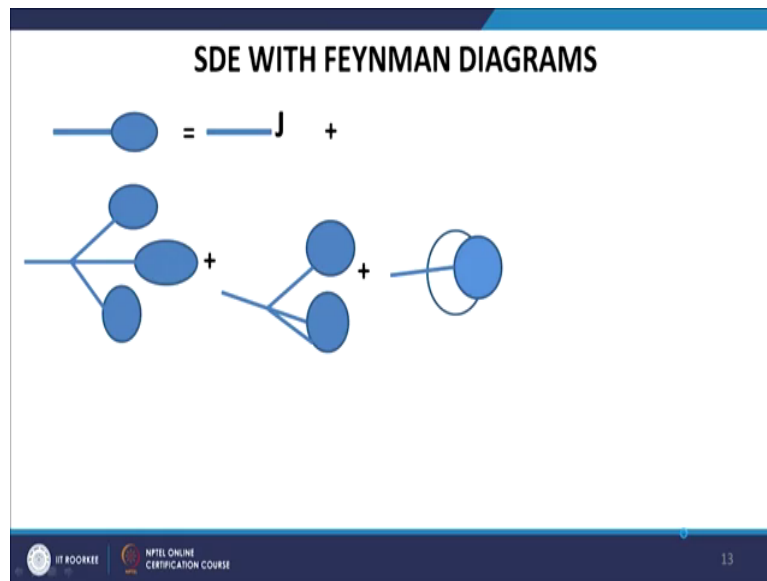

FOR ϕ^4 FIELD

$\phi(J) = \frac{J}{\mu} - \frac{\lambda_4}{6\mu} \left[\phi(J)^3 + 3\phi(J) \frac{\partial}{\partial J} \phi(J) + \frac{\partial^2}{(\partial J)^2} \phi(J) \right]$

  12

The field operator obviously, Schwinger-Dyson equation, that is given in the red boxes, it is given in 2 forms both of them hold for the phi 4 theory it takes the form given in the green box.

(Refer Slide Time: 04:50)

The Schwinger-Dyson equation can be arrived at by reference to the Feynman diagrams which are given on this slide.

The first diagram represents no interaction. The second diagrams represents an interaction with a 4 point vertex with each vertex branching of forming another blob or ending up at another blob. The second situation is where, 2 of the; 2 of the branches of the vertex reunite into a single blob. And the third situation is where all the 3 external lines from the vertex reunite to form into the same blob.

(Refer Slide Time: 05:34)

• $H_0 = \varepsilon +$  $+$  $+$ 

• $+$  $+$...

H_0 FOR φ^4 THEORY

• $H_0 = 1 - \frac{1 \lambda_4}{8 \mu^2} + \frac{1}{2} \left(\frac{1 \lambda_4}{8 \mu^2} \right)^2 + \frac{1}{16} \frac{\lambda_4^2}{\mu^4} + \frac{1}{48} \frac{\lambda_4^2}{\mu^4} + \dots$

• $= 1 - \frac{1 \lambda_4}{8 \mu^2} + \frac{35}{384} \frac{\lambda_4^2}{\mu^4} + \dots,$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

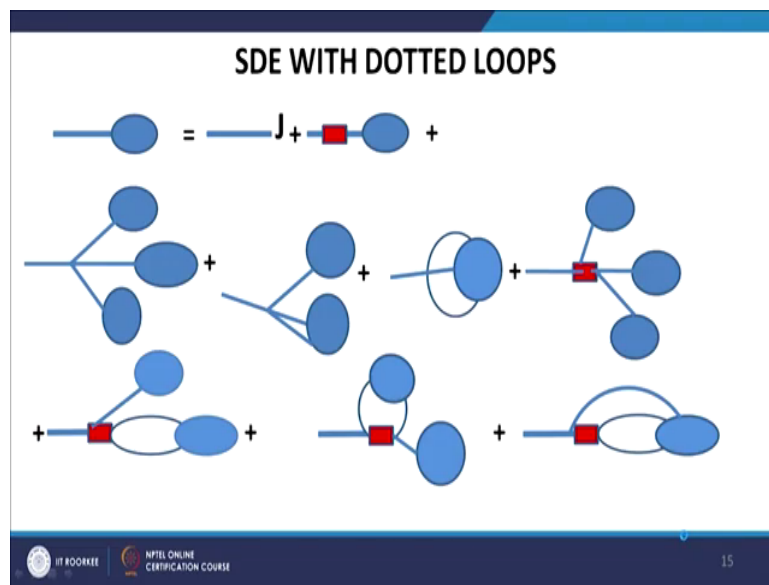

And, these 4 terms correspond respectively, to the Schwinger-Dyson equation that is given in the green box. The free field propagator is given in or the free field term is given in the first term. And the term the other 3 figures, the other 3 figures which involve a vertex in each case interaction with at the 4-point vertex in each case are given by the, given by the terms in the square brackets.

The first term ϕ^3 , the second term involving ϕ with the first derivative because, 2 branches emanating from the 4-point vertex reunite to a single blob, and in the third case the 3 branches emanating from the vertex all reunite to a common blob which is the last term on the green box given here.

The issue of vacuum bubbles was also discussed. These are the series of vacuum bubbles they are infinite series and they would perform a part of every expansion or every perturbative

expansion and they are excluded by dividing the entire perturbative expansion by this expression. In other words, when we write down the Feynman diagrams for a particular Green function or particular expansion we exclude the vacuum bubbles from the right hand side.

(Refer Slide Time: 07:20)

Then, we discussed the issue of loop divergences we represented them as dotted loops and, Feynman diagrams corresponding to the ϕ^4 theory with dotted loops takes the form which is given in your figure.

(Refer Slide Time: 07:31)

- $\phi = \frac{J}{\mu} - \frac{a_1}{\mu} \phi$
- $\frac{\lambda_4}{6\mu} \phi^3 - \frac{\hbar\lambda_4}{2\mu} \phi\phi' - \frac{\hbar^2\lambda_4}{6\mu} \phi''$
- $\frac{a_2}{2\mu} \phi^3 - \frac{\hbar a_2}{2\mu} \phi\phi' - \frac{\hbar a_2}{\mu} \phi\phi' - \frac{\hbar^2 a_2}{2\mu} \phi''$
- OR
- $(\mu + a_1)\phi = J - (\lambda_4 + 3a_2)(\phi^3 + 3\hbar\phi\phi' + \hbar^2\phi'')$

**SDE EQUATION FOR
DOTTED ACTION
(ϕ^4 THEORY)**

17

The Schwinger-Dyson equation, when we factor in the dotted diagrams, the loop divergences takes the form which is given in this figure. The interesting part is as we as I discuss towards the end of the last lecture, that the bare parameters of the action combined together or with a μ combines with a λ_4 and $3a_2$ in the Schwinger-Dyson diagram.

Which implies that whenever, an experimental measurement is made, the measured quantity will be $\mu + a_1$ and $\lambda_4 + 3a_2$ rather than μ and λ_4 and that enables us to do a renormalization in the event that a_1 and a_2 move towards infinity or tend to infinity by redefining μ and λ_4 also as infinities. So, that their sum appears in the theory as a finite quantity and the expression that we measured through experiments is a finite quantity.

(Refer Slide Time: 08:37)

<ul style="list-style-type: none"> • $\phi = \frac{J}{\mu} - \frac{B_1}{\mu} - \frac{B_2}{\mu} \phi - \frac{\lambda_3}{2\mu} \phi^2 - \frac{\hbar\lambda_3}{2\mu} \phi'$ • $-\frac{B_3}{2\mu} \phi^2 - \frac{B_3}{\mu} \phi^2 - \frac{\hbar B_3}{2\mu} \phi' - \frac{\hbar B_3}{\mu} \phi'$ • $\frac{\lambda_4}{6\mu} \phi^3 - \frac{\hbar\lambda_4}{2\mu} \phi\phi' - \frac{\hbar^2\lambda_4}{6\mu} \phi''$ • $\frac{B_4}{2\mu} \phi^3 - \frac{\hbar B_4}{2\mu} \phi\phi' - \frac{\hbar B_4}{\mu} \phi\phi' - \frac{\hbar^2 B_4}{2\mu} \phi''$ • OR • $(\mu + B_2)\phi = (J - B_1) - (\lambda_3 + 3B_3)(\phi^2 + \hbar\phi') - (\lambda_4 + 3B_4)(\phi^3 + 3\hbar\phi\phi' + \hbar^2\phi'')$ 	<p>SDE EQUATION FOR DOTTED ACTION ($\varphi^{3/4}$)</p>
--	---

18

And therefore, the theory can be expressed in terms of finite quantities.

(Refer Slide Time: 08:43)

RENORMALIZED ACTION

- **Undotted action:**
- $S(\varphi) = \frac{1}{2}\mu\varphi^2 + \frac{1}{24}\lambda_4\varphi^4$
- **Dotted (Renormalized Action):**
- $S(\varphi) = \frac{1}{2}(\mu + a_1)\varphi^2 + \frac{1}{24}(\lambda_4 + 3a_2)\varphi^4$

19

The as I mentioned just now, the original action was the bare action and the bare parameters was mu and lambda 4 given in the first equation on your slide. However, the dotted or the renormalized action takes the form mu plus a 1 as I mentioned mu is invariably replaced by mu plus a 1, lambda 4 is invariably replaced by lambda 4 plus a 2.

And, these are the quantises, that will be experimentally measured that are experimentally measured and therefore, if a 1 and a 2 tend to infinity we can redefine mu and lambda 4 also in similar manner so, that these expressions continue to be finite, and we get finite expressions for the Green functions.

(Refer Slide Time: 09:37)

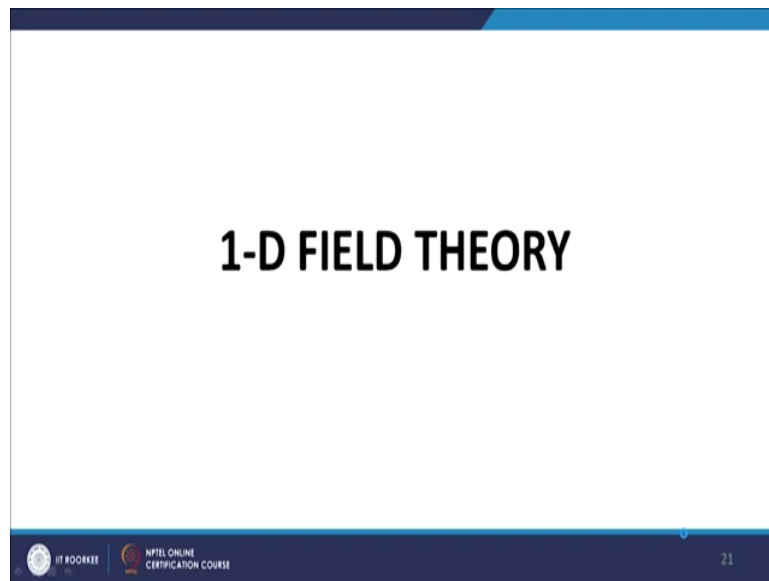

RENORMALIZATION GROUP EQUATION

$$\bullet \frac{d}{ds} w(s) = \beta(w)$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

We also arrived derived the renormalization group equation for the variation in scale variation energy of the renormalized parameters of the action and for this 0-dimensional field theory.

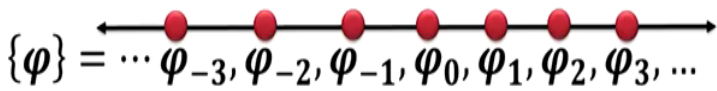

(Refer Slide Time: 09:58)

So, that is what we have done. So, far as far as zero-dimensional field theory is concerned.

(Refer Slide Time: 10:06)

- We start our study of one dimensional QFT by considering a theory of a countably infinite set of fields located at equidistant discrete points along a one-dimensional lattice.

The diagram shows a horizontal line with arrows at both ends, representing a one-dimensional lattice. Six red dots are placed at regular intervals along the line. Below the line, the field variables are labeled as $\{\varphi\} = \dots \varphi_{-3}, \varphi_{-2}, \varphi_{-1}, \varphi_0, \varphi_1, \varphi_2, \varphi_3, \dots$. The dots are positioned above the labels $\varphi_{-2}, \varphi_{-1}, \varphi_0, \varphi_1, \varphi_2, \varphi_3$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 22

We now, start one-dimensional field theory start the one- dimensional field theory by considering a lattice of one-dimensional lattice of equidistant points, discrete equidistant points the distance between each of them as we shall see later will represent by delta.

And, we shall go from this discrete model where each in the lattice is a discrete lattice and we shall move towards continuum by reducing the distance between the various points in the limit, that delta tends to 0; delta is the inter spatial distance.

And, we at each part on the lattice we identify a field with the respective suffixes phi 0, phi 1, phi 2, phi 3 and similarly, to maintain uniformity to or reflective symmetry we have phi minus 1, phi minus 2 and phi minus 3 and so on. We take the origin as the centre of the lattice.

(Refer Slide Time: 11:17)

- We denote by $\{\varphi\}$ the set of all these fields:
- $\{\varphi\} = \cdots \varphi_{-3}, \varphi_{-2}, \varphi_{-1}, \varphi_0, \varphi_1, \varphi_2, \varphi_3, \cdots$
- where the field labels run from $-\infty$ to $+\infty$.
- Similarly, there is the collection of all the corresponding sources, denoted by $\{J\}$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

Collectively the fields are denoted by φ , the set φ and the field labels as I mentioned run from minus infinity to plus infinity. And similarly, we have a collection of all sources and the sources are also collectively represented by J .

(Refer Slide Time: 11:36)

- If there is:
 - no self interaction in the fields
 - no mutual interaction among various fields, the action takes the form:

$$S(\{\varphi\}) = \sum_n \left[\frac{1}{2} \mu \varphi_n^2 \right]$$

IT KOOKEE NPTEL ONLINE CERTIFICATION COURSE 24

For the moment, let us start with the simplest case if there is no self-interaction and there is no interaction between the neighbouring or any interaction between distinct fields between different fields then the action takes the form given in the green box here.

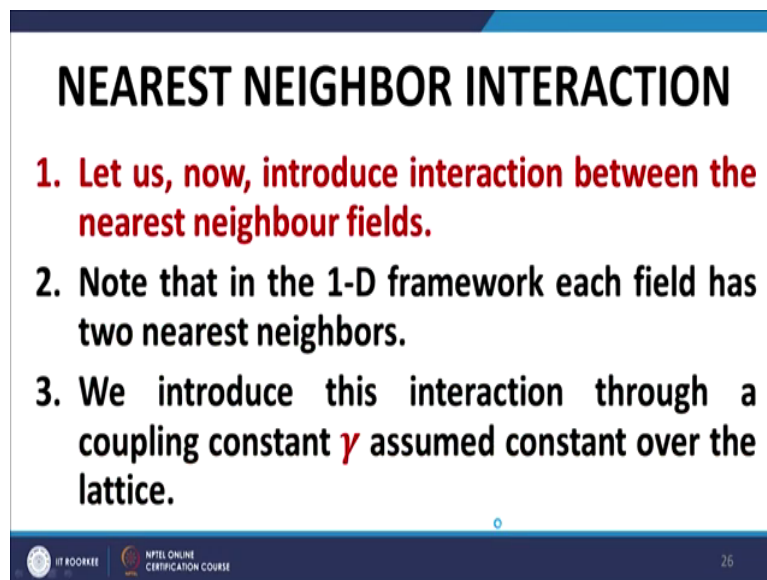

(Refer Slide Time: 11:56)

- The generating functional then becomes:
$$Z(J) = \int \prod_n d\varphi_n \exp\left(-\sum_n \left(\frac{1}{2}\mu\varphi_n^2 - J_n\varphi_n\right)\right)$$
$$= \prod_n \int d\varphi_n \exp\left(-\left(\frac{1}{2}\mu\varphi_n^2 - J_n\varphi_n\right)\right)$$
- Thus, the path integral factorizes and the fields evolve independently of each other leading to no interesting physics. There is no correlation between the fields.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

And, the generating functional can be simplified to take the form given in the green box here. Straight away it factorizes the generating functional factorizes itself, and each field in a sense evolves independently of all others there is no correlation and therefore, there is no interesting physics involved in this particular case.

(Refer Slide Time: 12:24)

NEAREST NEIGHBOR INTERACTION

- 1. Let us, now, introduce interaction between the nearest neighbour fields.**
- 2. Note that in the 1-D framework each field has two nearest neighbors.**
- 3. We introduce this interaction through a coupling constant γ assumed constant over the lattice.**

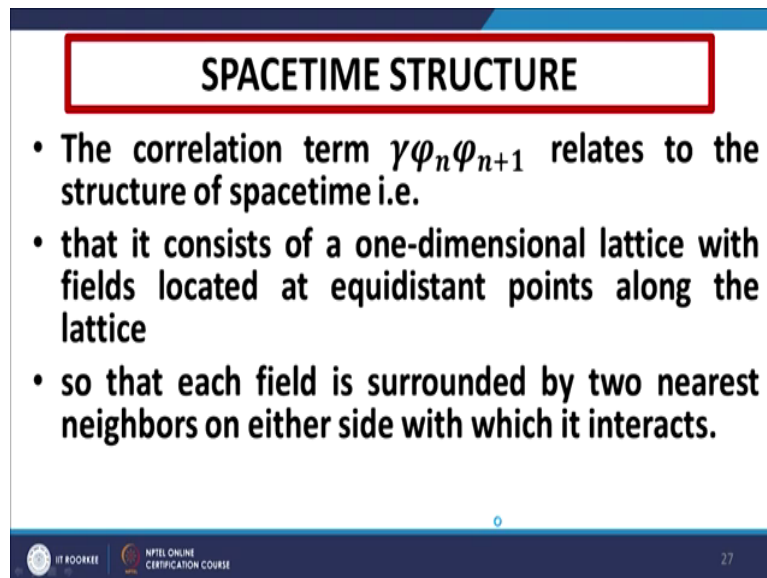

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 26

So, what we do now is we introduce some kind of interaction having studied the ϕ^4 interaction already, we keep it in abeyance for the moment we introduce interaction between nearest neighbors. In other words every field on the lattice interacts with one neighbor towards left, and the other neighbor towards right.

Recall, that in this framework each in the 1-dimensional lattice framework each field is surrounded by two neighbors, one to the left and one to the right. And we assume that the field interacts with only these two neighbors that is the neighbor to the left and the neighbor to the right.

And the coupling or the interaction is reflected by a coupling constant that is gamma and that is constant throughout the lattice. In other words that, justifies the assumption that the lattice spacing is uniform.

(Refer Slide Time: 13:19)

SPACETIME STRUCTURE

- The correlation term $\gamma\varphi_n\varphi_{n+1}$ relates to the structure of spacetime i.e.
- that it consists of a one-dimensional lattice with fields located at equidistant points along the lattice
- so that each field is surrounded by two nearest neighbors on either side with which it interacts.

IT KOOBEE | NPTEL ONLINE CERTIFICATION COURSE | 27

So, this correlation term will take the form $\gamma\varphi_n\varphi_{n+1}$. And the very fact that it takes this form related intimately to the structure of the lattice being a 1-dimensional lattice, and therefore, two neighbors one to the left and one to the right the field interacts with these two neighbors, which is captured by this particular term which as you will see goes into the action for the field theory present field theory.

(Refer Slide Time: 13:57)

The action is given by :

$$S(\{\varphi\}) = \sum_n \left[\frac{1}{2} \mu \varphi_n^2 - \gamma \varphi_n \varphi_{n+1} \right]$$

where γ captures the magnitude of the interactions between neighboring fields.

The action integral is :

$$Z(0) = \int [D\varphi] \exp \left(- \sum_n \left(\frac{1}{2} \mu \varphi_n^2 - \gamma_n \varphi_n \varphi_{n+1} \right) \right)$$

  28

So, the action is given by as I mentioned they action by incorporate the mutual interaction term in addition to the free action $\frac{1}{2} \mu \varphi_n^2$; the red box expression minus $\gamma \varphi_n \varphi_{n+1}$. The second term is obviously, the term that captures the mutual interaction between neighbouring fields.

(Refer Slide Time: 14:23)

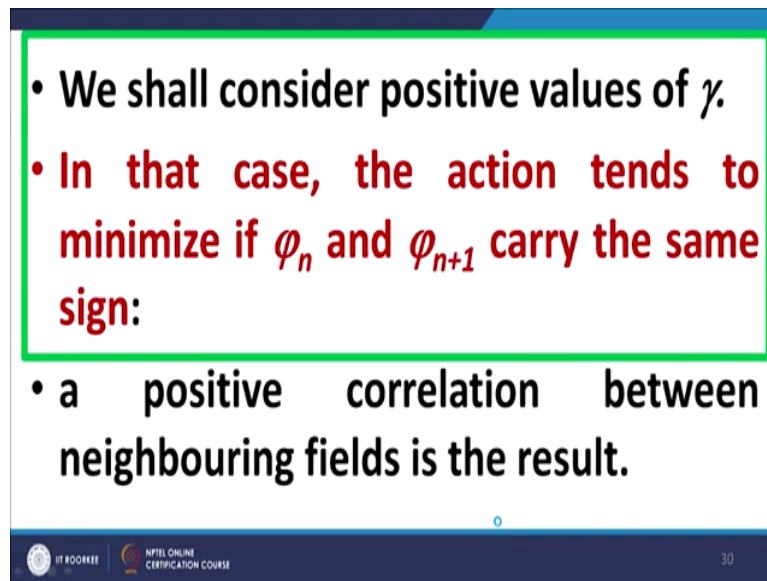

The generating functional is :

$$Z(\{\varphi\}\{J\}) = \int [D\varphi] \exp \left(-\sum_n \begin{pmatrix} \frac{1}{2} \mu \varphi_n^2 \\ -\gamma_n \varphi_n \varphi_{n+1} \\ -J_n \varphi_n \end{pmatrix} \right)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 29

And, the action integral takes this form. The generating functional and the generating function, for the moment is still the function it takes this form we introduce sources each source corresponding to each field independent one to one field source relationship and that is reflected in the generating function given in the green box on this slide.

(Refer Slide Time: 14:44)

The slide features a white background with a green border. It contains two bullet points. The first bullet point is in black text, and the second is in red text. At the bottom of the slide, there are logos for IIT Roorkee and NPTEL Online Certification Course, along with the number 30.

- We shall consider positive values of γ .
- In that case, the action tends to minimize if φ_n and φ_{n+1} carry the same sign:

- a positive correlation between neighbouring fields is the result.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 30

We consider positive values of gamma, positive values of gamma implies that the action between φ_n and φ_{n+1} minimizes if they carry the same sign. In other words if φ_n and φ_{n+1} carry the same sign and gamma is positive the action will minimize. So, there is a positive correlation between the neighbouring fields in view of gamma being taken as positive.

(Refer Slide Time: 15:15)

TRANSLATION INVARIANCE

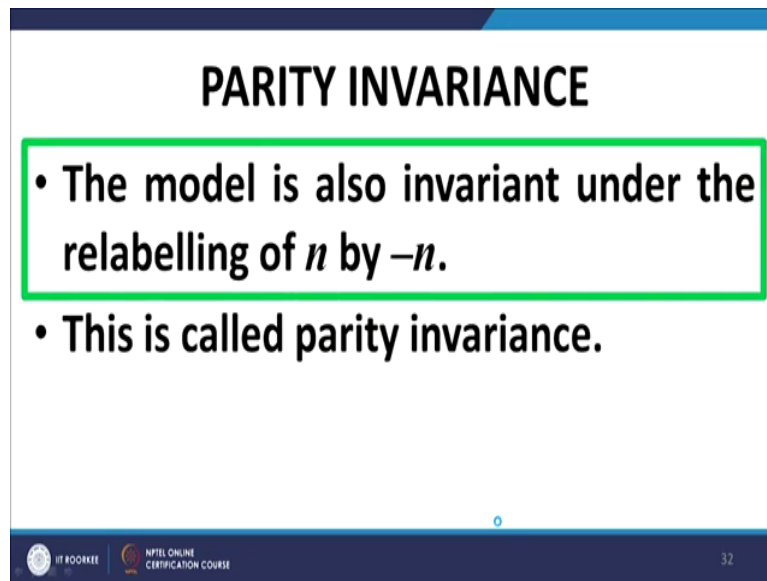

- The action has be such as to be:
- invariant under the relabelling of n by $n+K$ with any fixed K .
- This is called translation invariance.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 31

Then, we have translation invariance, in other words we want that if the entire set of fields the entire structure of fields is shifted by a constant or the indices are shifted indices of each fields are shifted by a constant k , the structure of the physical theory underlying physical theory does not change.

That means if we re label; n by n plus K , capital K for any fixed K each of these; each of these labels are renamed by as 1 say ϕ_0 is named as ϕ_k , ϕ_1 is named as $\phi_1 + k$ and so on. The field theory does not change.

(Refer Slide Time: 16:01)

PARITY INVARIANCE

- The model is also invariant under the relabelling of n by $-n$.
- This is called parity invariance.

0

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 32

Then, we need also involve we also have parity invariance, in other words if we change ϕ , if we interchange n and $-n$, the theory should or the theory will not change.

(Refer Slide Time: 16:14)

The action is given by: $S(\{\varphi\}) = \sum_n \left[\frac{1}{2} \mu \varphi_n^2 - \gamma \varphi_n \varphi_{n+1} \right]$

$$\frac{\partial S}{\partial \varphi_n} = \mu \varphi_n - \gamma \varphi_{n-1} - \gamma \varphi_{n+1}$$

$$S' \left(\phi_n(J_n) + \frac{\partial}{\partial J_n} \right) e(J) = \mu \phi_n(J_n) - \gamma (\phi_{n-1} + \phi_{n+1})$$

SDE for field function $S' \left(\phi_n(J_n) + \frac{\partial}{\partial J_n} \right) e(J) = J_n$

or $\phi_n(J_n) = \frac{J_n}{\mu} + \frac{\gamma}{\mu} (\phi_{n-1} + \phi_{n+1})$

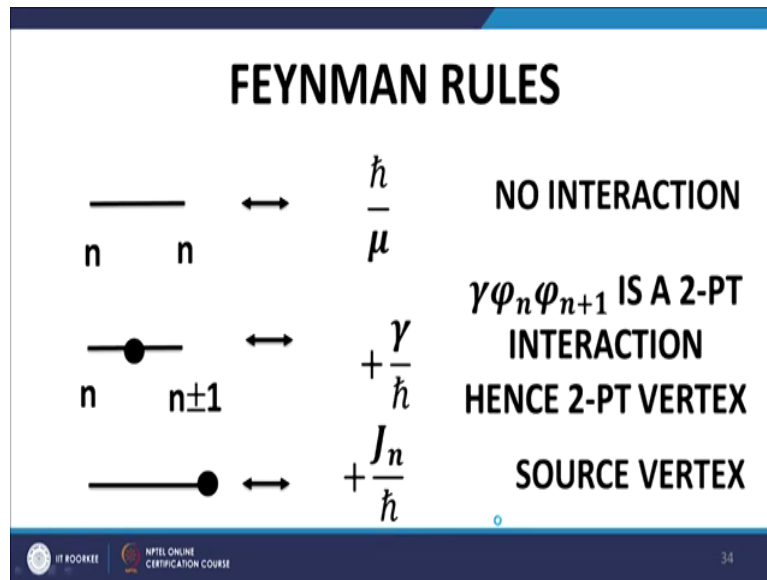

So, the action as I mentioned earlier is given by the expression in the red box above. The first derivative of the action with respect to the field variables is given by in this expression mu phi n minus gamma phi n minus 1 minus gamma phi n plus 1.

Please note, there will be 2 interaction terms: one corresponding to each of the neighbors in left neighbor and the right neighbor. The n minus 1th neighbor and the n plus 1th neighbour. In other words phi n interacts with the phi n plus 1th neighbor and the phi n minus 1th neighbor.

So, Schwinger-Dyson equation therefore, takes the form which is given, this Schwinger-Dyson equation for the field function is given by S dash of phi plus del by del J of the unit function which on simplification gives us the expression right at the bottom green box

of the of your slide. This is the Schwinger-Dyson equation for the field function of the current model.

(Refer Slide Time: 17:23)

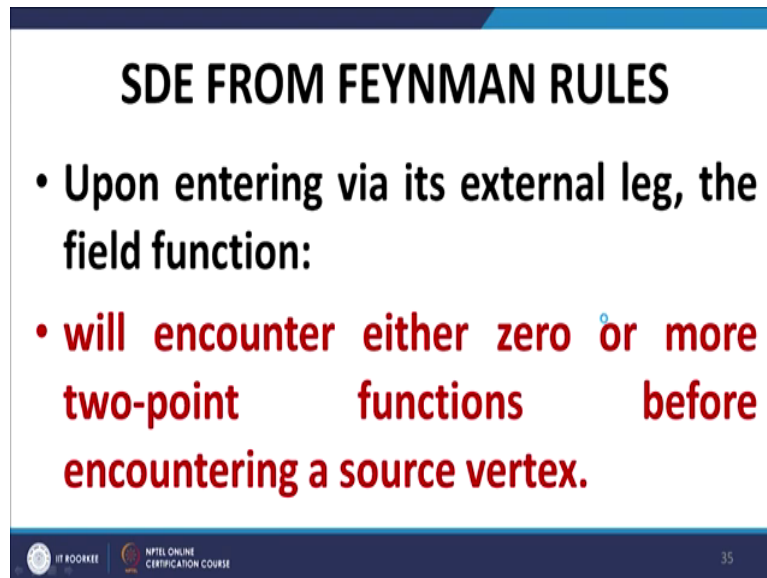

The corresponding Feynman rules, are simple. The first rule represents no interaction. The second rule represents interaction at one-point; the two-point vertices because; that means, the field is interacting with its nearest neighbor therefore, with the Feynman rule involves the field n , the incoming field n and the outgoing field either $n + 1$ or $n - 1$. This is a two-point vertex because, the interaction involves the incoming field and this nearest neighbor.

And, the interaction term is given by $\gamma \phi_n \phi_{n+1}$. So, the vertex captures the two-point interaction between the fields, the field n and the field $n + 1$; field at $n + 1$ minus 1, field at a point n and the field at point $n + 1$. And then, the rule for the

source is given right at the bottom of your slide. The line plus the blob at the right hand is the source vertex.

(Refer Slide Time: 18:41)

SDE FROM FEYNMAN RULES

- Upon entering via its external leg, the field function:
- will encounter either zero or more two-point functions before encountering a source vertex.

IT 400KKEE NPTEL ONLINE CERTIFICATION COURSE 35

So, Schwinger-Dyson equation can be derived from the Feynman rules, upon entering the external leg, the field function will either encounter no two-point vertex or one or more two-point vertices and the situation is reflected in the Schwinger.

(Refer Slide Time: 19:00)

A. The field φ_n on entering the external leg encounters zero 2-pt vertices before hitting the source vertex. 

B. The field φ_n on entering the external leg interacts with the field to its left (2-pt vertex) and then encounters either zero or more two point vertices before hitting the source (collectively represented by blob). 

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 36

If the field, φ_n encounters no 2-point vertices zero 2-point vertices, and hits the source you get a diagram of the form that is given in in point a. If the field encounters one vertex, then the diagram then the interaction is given in the diagram the blob the black blob and thereafter, which may again encounter either a zero vertex or another 2-point vertex and so on. Which is the entire thing is captured by the big blue blob.

(Refer Slide Time: 19:39)

C. The field φ_n on entering the external leg interacts with the field to its right (2-pt vertex) and then encounters either zero or more two point vertices before hitting the source.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 37

And similarly, in the interaction with the field to the right will be represented by a similar figure.

(Refer Slide Time: 19:47)

SDE FROM FEYNMAN RULES

$$\phi_n = \frac{J_n}{\mu} + \frac{\gamma}{\mu} (\phi_{n-1} + \phi_{n+1})$$

The identity of the field is indicated by its label.

o

IIT ROORKEE
 NPTEL ONLINE CERTIFICATION COURSE
 38

So, in totality what we have is if a field enters the field function enters through an external leg either it encounters 0 vertex, and it directly hits the source which is given in the first diagram, or it encounters one-two point vertex which changes it into either n minus 1 or n plus 1 and then, it again may encounter a 0, may encounter a no vertex or encounter one or more two point vertices that entire story of encountering no vertex or two-point one or more two-point vertices is captured by the blue blob.

Which is simply, a reflection of the blue blob that you have on the left hand side. What are we representing on the left hand side, we are representing an entering field ϕ_n and which may encounter either no vertex or it may encounter one or more two-point vertices the entire thing is captured by the blue blob.

Here, the same thing is happening it encounters one vertex, which with which it interacts two-point interaction and then again it ends up with a situation where the field $n - 1$ either encounters a 0 vertex, as I encounters a 0 vertices or encounters one or more two-point vertices which is again captured by the two-point by the blue blob.

Similarly, in the third case the field n interacts with its neighbor to get the field the field $n + 1$, and again the field $n + 1$ may either encounter no vertex or it may encounter one or more two-point vertices, the entire situation of the field $n + 1$ cap and encountering zero or more than one or more two- point vertices is captured by the blue blob. So, this is a kind of a recursive relationship.

And, what we get is ϕ_n is equal to this particular first case, which is which evaluates this dot evaluates to 1 to J_n . And the straight line evaluates to 1 upon μ . So, it gives us J_n upon μ , here the interaction what else evaluates to γ , the entering line evaluates to 1 upon μ and then, we have this blue blob which evaluates to $\phi_n - \phi_{n-1}$ and similarly, the third figure also evaluates to γ upon μ ϕ_{n+1} . So, we have this recursive relation which is the Schwinger-Dyson equation for the given field ϕ_n .

PROPAGATORS

IIT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE

39

(Refer Slide Time: 22:46)

- Consider the fact that, upon entering the field function via its external leg, one must encounter either zero or more two-point functions before encountering a source vertex. Let us denote by:

$$\Pi_{n,m} \equiv \text{---} \overset{\circ}{\bullet} \text{---}$$

- the total set of diagrams that contain only two-point vertices (or no vertices), and have fields n and m at its external legs.
- Let us call it the propagator.

(Refer Slide Time: 22:52)

SDE FROM FEYNMAN RULES

$$\phi_n = \frac{J_n}{\mu} + \frac{\gamma}{\mu} (\phi_{n-1} + \phi_{n+1})$$

The identity of the field is indicated by its label.

38

Now, we introduce the concept of propagators. Here, just let me going back a bit, here what we were talking about is the field function, entering through one of the external legs, and emerging in any of the possible states. Any possible states that is given by the blue blob.

Here, we have a more specific expression capital pi n comma n represents if nth field entering and the interaction and emerging as a field m. So, here in the previous case we were we had the emerging field could be any field.

Here, in the case of a propagator we identified, the emerging field the outgoing field the outgoing leg, as leg m. So, we have an inter incoming leg incoming external leg, phi n that is the incoming field and the outgoing field is phi m. So, that is represented by the propagator pi

n comma m . So, this is the difference, this is very important that the as far as the incoming field is concerned we have a single field here, we have a single field in the previous case.

However, in the outgoing case we did not restrict ourselves to any single field in the previous case here, we are restricting ourselves to a particularly identified field that is field m . So, this red blob represents the total number of diagrams that contain only two-point vertices or no vertices, no vertices or two-point vertices and that has field's n and m at the external legs.

So, the field's n and the field m are now identified. If you compare this with the previous case here, we the incoming field was identified. But, the outgoing field was not identified, the outgoing fields could have been any field and this blob consisted of all two-point diagrams zero or more then one or more two-point diagrams all these were captured in this blue blob.

Zero or more two-point vertices I am sorry, not diagrams zero or more two-point vertices.

(Refer Slide Time: 25:15)

$$\text{Diagram: } n \text{ --- } \text{blue blob} = \sum_m \text{Diagram: } n \text{ --- } \text{red blob} \text{ --- } J_m$$

$$\phi_n(J_n) = \sum_m \Pi_{n,m} J_m$$

SDE IN TERMS OF PROPAGATOR

Since the propagator relates to a particular outgoing external leg m but the field can evolve into any available state i.e. any m , the propagator needs to be summed over m to get the field function.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 41

So, that is the difference. So, in other words if we have to express the field function in terms of the propagator, we have the field n ; now this field n after in the blue blob can emerge any one of the out possible outgoing states of the system.

Where there whereas, in the propagator we have the field n and it could emerge as a particular outgoing state m and therefore, the relation between the two diagrams is that the right hand side diagram must be summed over all the possible values of out outgoing states m to arrive at the diagram given on the left hand side.

In other words, what we get is ϕ_n is equal to summation over m summation over the possible outgoing fields $\Pi_{n,m}$ that is the propagator J_m , J_m is the source corresponding to

the field ϕ_n , J_n is the source corresponding to the field ϕ_n . So, this is the Schwinger-Dyson equation in terms of the propagator for the simple theory that we have.

(Refer Slide Time: 26:33)

F / A : SDE $\phi_n(J_n) = \frac{J_n}{\mu} + \frac{\gamma}{\mu}(\phi_{n-1} + \phi_{n+1})$

We express field function $\phi_n(J_n)$ in an alternative form :

$$\phi_n(J_n) = \sum_m \Pi_{n,m} J_m$$

$$= \sum_m \Pi_{n,m} \left[\mu \phi_m(J_m) - \gamma (\phi_{m-1} + \phi_{m+1}) \right]$$

$\Pi_{n,m}$ is called the propagator.

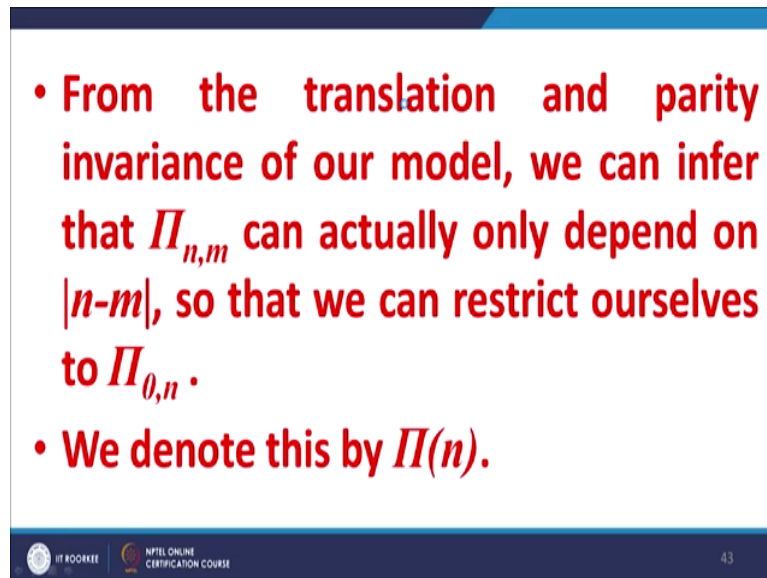

IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE 42

This is we can express this as a recursive relation, we have the Schwinger-Dyson equation for ϕ_n therefore, we can change indices and we can write the Schwinger-Dyson equation for ϕ_m in the this form, simply substituting n equal to m and we have the expression for ϕ_m ; we substitute that value of ϕ_m in this expression we substitute the value of J_m from this expression for ϕ_m and we arrive at the expression in the green box.

Let me repeat, we have this Schwinger-Dyson equation for ϕ_n given in the red box. From here, we can obtain a change indices to m , and we can write the expression for ϕ_m from where we can obtain the expression for J_m and we can substitute J_m in the expression for the

field ϕ_n using the propagator expression and we arrive at the expression recursive relation given in the green box at the bottom of your slide.

(Refer Slide Time: 27:44)

- From the translation and parity invariance of our model, we can infer that $\Pi_{n,m}$ can actually only depend on $|n-m|$, so that we can restrict ourselves to $\Pi_{0,n}$.
- We denote this by $\Pi(n)$.

IT KOOKEE NPTEL ONLINE CERTIFICATION COURSE 43

Now, because of the translation and parity invariances we can make a simplification in the representation of the propagator $\Pi_{n,m}$, because of the translation invariance, the propagator must depend only on the difference $n - m$, and secondly, because of parity invariance it can be propagated from n to m ; would be the same as the propagator from m to n therefore, we can write it as $\Pi_{n,m}$ is equivalent to writing $\Pi_{|n-m|}$.

We can further simplify it by taking by using one of them as 0. As, the origin because it is translation invariant. So, the origin can be shifted without modifying the propagator and therefore, we can write $\Pi_{n,m}$ as $\Pi_{0,n}$ also. And which we represent by $\Pi(n)$.

So, to repeat because of translation invariance and parity invariance operating in tandem, we can write π_n as π_0 because first of all because of translation invariance, you can change shift the origin and because of parity invariants 0 to n or n to 0 makes no difference. So, you can identify it either way and you can write it as π_n .

(Refer Slide Time: 29:17)

SDE FOR THE PROPAGATOR

$$\Pi(n) = \frac{\hbar}{\mu} \delta_{0,n} + \frac{\gamma}{\mu} (\Pi(n+1) + \Pi(n-1))$$

44

Now, Schwinger-Dyson equation for the propagator, let us talk about the propagator π_n is supposed to represent π_0 comma n . In other words what is π_0 comma n ? π_0 entering the propagator the field ϕ_0 entering and the field ϕ_n emerging from the external leg, that is what the propagator π_0 comma n is supposed to represent, that is the left hand side here.

Now, it can so happen that n is nothing, but the 0th field, in other words the particle does not interact at all and comes out without interaction which is represented by the straight line, but which will happen only if n is equal to 0.

So, that is represented by δ_{0n} of course, the straight line will evaluate to 1 upon μ then, the particle could interact have a could face a 2 point vertex, a 2 point interaction and therefore, it can either convert which can either convert it to plus 1 or it can convert to minus 1 and after conversion to plus 1 or minus 1 the particle will again face a situation where, because it has to emerge at the field n .

Emerge at the field n it has to face a situation where, the it faces a propagator which transforms it from the state minus 1 to the state n . In other words let me repeat if ϕ_0 enters the system, interacts at the two-point vertex giving ϕ_{-1} and ϕ_{-1} then, is transformed by the propagator to ϕ_n . Because, we want the external leg outgoing external leg to be ϕ_n .

And, the third case can be ϕ_0 encounters the two-point vertex gets converted to ϕ_1 , and again it interacts with the propagator because it has to be converted to ϕ_n . So, making use of these 3 these are the 3 possible diagrams, if you evaluate the second first diagram I have discussed.

If you evaluate the second diagram the black blob will evaluate to γ , the entering line will evaluate to 1 upon μ and because we are transforming or the propagator is transforming from minus 1 to n , it gives me $\pi_n + 1$, and similarly the last diagram evaluates to π_γ upon μ $\pi_n - 1$. And the equation in the green box therefore, is the recursive relation for the propagator. After the break we will proceed to solve this equation.

Thank you.
