**Professor J.P Singh**  
**Department of Management Studies**  
**Indian Institute of Technology, Roorkee**  
**Lecture 43**  
**Mean Variance Portfolio Optimization - III**

Welcome back. So, let us continue from where we left off but before that as usual A quick recap of the important points that we discussed in the last lecture. We started discussing the mean variance portfolio optimization theory and we defined certain terms and arrived at certain expressions for the portfolio possibilities curve.

(Refer Slide Time: 00:47)

**EXPECTED RETURN OF A PORTFOLIO**

The expected return of a portfolio of securities  
with composition vector:

$$X = \{X_i, i = 1, 2, 3, \dots, N\}; \sum_{i=1}^N X_i = 1 \quad (6)$$

is given by:  $E(R_p) = \sum_{i=1}^N X_i E(R_i)$  or  $\bar{R}_p = \sum_{i=1}^N X_i \bar{R}_i \quad (7)$

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 2

We started with the expected return of A portfolio with the expression that is given in equation 7 here on the slide with for the composition vector which is given in equation 6, composition vector means the weights attached to the various securities that form the portfolio in terms of money values. A fraction of money values of the total that is represented by the various securities that form the portfolio. The variance of the portfolio is defined by equation 8 here on the slide, there are three different ways in which we can express the variance of A portfolio.

(Refer Slide Time: 01:21)

## VARIANCE OF A PORTFOLIO

$$\begin{aligned}\sigma_p^2 &= E \left[ R_p - E(R_p) \right]^2 = \sum_{i=1}^N \sum_{j=1}^N X_i X_j \sigma_{ij} \\ &= \sum_{i=1}^N X_i^2 \sigma_i^2 + \sum_{i=1}^N \sum_{\substack{j=1 \\ i \neq j}}^N X_i X_j \sigma_{ij} \\ &= \sum_{i=1}^N X_i^2 \sigma_i^2 + 2 \sum_{i=1}^N \sum_{\substack{j=1 \\ i < j}}^N X_i X_j \sigma_{ij}\end{aligned}\quad (8)$$

The first one is in the first equation, the second equation and the third equation. So, these three are different ways of expressing the same quantity, the variance of A portfolio of securities.

(Refer Slide Time: 01:37)

## FOR TWO SECURITY PORTFOLIO

$$\bar{R}_p = X_1 \bar{R}_1 + X_2 \bar{R}_2 \quad (9)$$

$$\begin{aligned}\sigma_p^2 &= X_1^2 \sigma_1^2 + X_2^2 \sigma_2^2 + 2X_1 X_2 \sigma_{12} \\ &= X_1^2 \sigma_1^2 + X_2^2 \sigma_2^2 + 2\rho_{12} X_1 X_2 \sigma_1 \sigma_2\end{aligned}\quad (10)$$

$$X_1 + X_2 = 1 \quad (11)$$

Now, then we moved over to the two-security problem in the two security problem the expressions that we saw just now A few seconds back translate to rather simple expressions in terms of the composition vector of  $x_1$  and  $x_2$  as the equations 9, 10 with the aggregate of the composition vectors being equal to one the sum of the composition vectors being sorry sum of the compositions rather being equal to 1. So, 9 represents the expected return of A two-security

portfolio, 10 represents the variance of A 2 security portfolio and 11 gives you the sum of the compositions of the constituents of the composition vector.

(Refer Slide Time: 02:18)

**Eliminating  $X_2$**

$$E(R_p) = X_1 E(R_1) + (1 - X_1) E(R_2) \text{ or}$$
$$\bar{R}_p = X_1 \bar{R}_1 + (1 - X_1) \bar{R}_2 \quad (12)$$
$$\sigma_p^2 = X_1^2 \sigma_1^2 + (1 - X_1)^2 \sigma_2^2 + 2X_1(1 - X_1)\rho\sigma_1\sigma_2 \quad (13)$$

**Eliminating  $X_1$  between eqs. (12) & (13), we obtain the equation for the PPC for the two security case:**

5

We if we eliminate  $X_2$  among these equations among this set of equations what we get is equation number 12 and the next equation gives you the variance of the two security portfolio in terms of  $X_1$  and using these two equations again we can eliminate  $X_1$  as well so we can eliminate both  $X_1$  and  $X_2$  and we get the equation of A curve in terms of as A functional relationship between the x the variance or standard deviation of the portfolio and the expected return of the portfolio. With the equation of that curve which represents the functional relationship between the standard deviation of the portfolio which is captured by x here abbreviated by x represented by x and the expected return which is represented by y is given in equation number 14 here on this slide.

(Refer Slide Time: 03:15)

$$x^2 - y^2 \frac{(\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)}{(\bar{R}_1 - \bar{R}_2)^2} + 2y \frac{[\bar{R}_2\sigma_1^2 + \bar{R}_1\sigma_2^2 - (\bar{R}_1 + \bar{R}_2)\rho\sigma_1\sigma_2]}{(\bar{R}_1 - \bar{R}_2)^2} - \frac{(\bar{R}_2^2\sigma_1^2 + \bar{R}_1^2\sigma_2^2 - 2\bar{R}_1\bar{R}_2\rho\sigma_1\sigma_2)}{(\bar{R}_1 - \bar{R}_2)^2} = 0 \quad (14)$$

$$E(R_p) \equiv \bar{R}_p \equiv y, \quad \sigma_p = x$$

The equation of the PPC can be written as :

$$\frac{x^2}{c - \frac{f^2}{b}} - \frac{\left(y\sqrt{b} - \frac{f}{\sqrt{b}}\right)^2}{c - \frac{f^2}{b}} = 1 \quad (16) \text{ or } x^2 - by^2 + 2fy - c = 0 \quad (17)$$

$$b = \frac{(\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)}{(\bar{R}_1 - \bar{R}_2)^2}; \quad f = \frac{[\bar{R}_2\sigma_1^2 + \bar{R}_1\sigma_2^2 - (\bar{R}_1 + \bar{R}_2)\rho\sigma_1\sigma_2]}{(\bar{R}_1 - \bar{R}_2)^2};$$

$$c = \frac{(\bar{R}_2^2\sigma_1^2 + \bar{R}_1^2\sigma_2^2 - 2\bar{R}_1\bar{R}_2\rho\sigma_1\sigma_2)}{(\bar{R}_1 - \bar{R}_2)^2}$$

And we saw that this equation can also be written in the standard form of A hyperbola that is x square upon A square minus y square upon B square is equal to 1 which is equation 16 or in the form of A second degree equation as x square minus B y square plus 2 fc plus 2 F y minus C is equal to 0. I repeat x square minus B y square plus 2 F y minus e is equal to 0 which is equation number 17 where B F and C have the values assigned to them as shown in this particular slide.

(Refer Slide Time: 04:06)

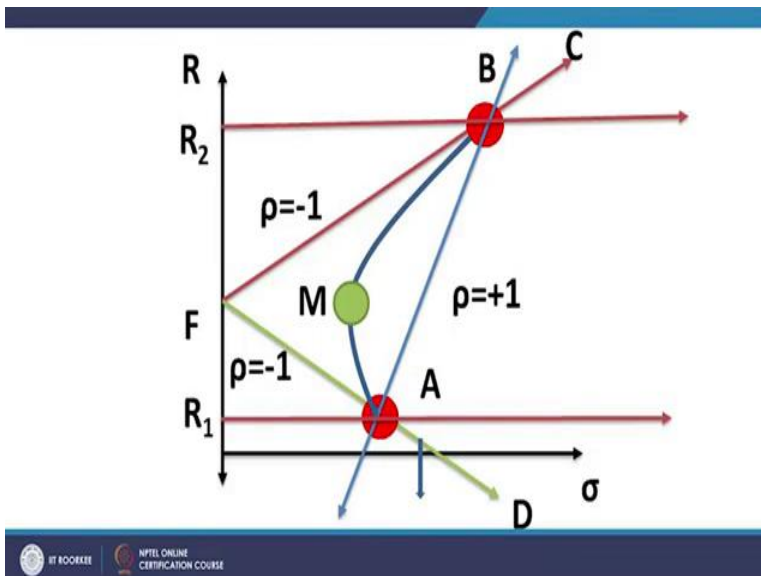

## IMPORTANT FEATURES OF PPC

- $x \equiv \sigma$  can never be negative, by definition;
- Assuming **no short sales**, the portfolio return  $y \equiv R_p$  must necessarily lie between  $R_1$  &  $R_2$  so that no point of the PPC can lie outside the region bounded by the lines parallel to X-axis through  $R_1$  &  $R_2$ ;
- (c) We must also have  $|\rho| \leq 1$

The important features of this portfolio possibilities curve which as I mentioned is A hyperbola represented by the equation that we saw just now equation number 14, first thing is that the portfolio possibilities curve must necessarily be confined to the right half plane because sigma cannot take values, negative values and hence there will be no point on the portfolio possibilities curve which lies to the left or lies in the left half plane. All the, well all the points on the portfolio possibilities curve must necessarily lie on the right half plane that is to the right of the origin with respect to the y axis.

(Refer Slide Time: 04:34)

And if you assume that no short sales are allowed if you assume that no short sales are allowed then the portfolio return will be necessarily between the returns or the expected returns of the two securities constituting the portfolio that is E of R1 and E of R2 which i have abbreviated as R1 and R2 and therefore there would be no point on the portfolios possibilities curve that would lie outside the region or which is constrained by the straight lines through the points 0 comma R1 and 0 comma R2 parallel to the x axis.

Now, then we moved over to the limiting cases of rho ah the limiting cases of rho arise from the values of rho equal to plus 1 and rho equal to minus 1, we examine these two cases; rho equal to plus 1 gives us the perfectly correlated securities perfectly correlated assets and rho equal to minus 1 gives us the perfectly anti correlated assets.

(Refer Slide Time: 05:44)

### PERFECTLY CORRELATED ASSETS $\rho=+1$

$$X_1 < \frac{\sigma_B}{\sigma_B - \sigma_A}; y = \frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 - \sigma_2)} X + \frac{(\bar{R}_2 \sigma_1 - \bar{R}_1 \sigma_2)}{(\sigma_1 - \sigma_2)} \quad (20)$$

$$X_1 > \frac{\sigma_B}{\sigma_B - \sigma_A}; y = -\frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 - \sigma_2)} X + \frac{(\bar{R}_2 \sigma_1 - \bar{R}_1 \sigma_2)}{(\sigma_1 - \sigma_2)} \quad (21)$$

In the case of the perfectly correlated assets what we have is we have the equation of the portfolio possibilities curve represented by A pair of straight lines 20 and 21, the equation 20 would operate in the region where X1 is less than sigma B upon sigma B minus sigma A and equation 21 would operate in the region where X1 is greater than sigma B divided by sigma B minus sigma A. The pictorial representation of the portfolio possibilities curve in the case of rho equal to plus 1 is given in the slide.

(Refer Slide Time: 06:38)

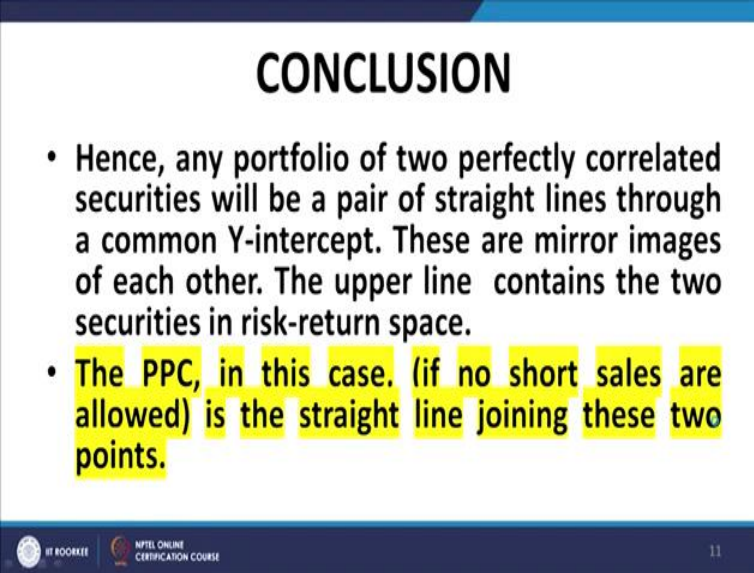

You can see that both the securities A and B lie on the upper straight line that is the straight line represented by equation 20 and the region in the region between A and B both A and A and B are long, both the securities A and B are long beyond B towards C B continues to be long A becomes short and beyond A towards F and along F d in the entire region A F d B is short and A is long.

So, in this case the portfolio possibilities curve translates to A pair of straight lines and the intersecting the y axis at the risk free rate which is given by which is given by  $R_2 \sigma_1 \text{ minus } R_1 \sigma_1 \text{ divided by } \sigma_1 \text{ minus } \sigma_2$  that is represented by the point F in this diagram. In the conclusion as far as this uh situation is concerned.

When we have got two assets, two risky securities perfectly correlated with each other those prices or whose returns are perfectly correlated then this situation or the result is that the portfolio of two perfectly correlated securities will be A pair of straight lines will be represented on A pair of straight lines and risk return space through A common y intercept which represents the risk free rate.

(Refer Slide Time: 07:41)

## CONCLUSION

- Hence, any portfolio of two perfectly correlated securities will be a pair of straight lines through a common Y-intercept. These are mirror images of each other. The upper line contains the two securities in risk-return space.
- The PPC, in this case, (if no short sales are allowed) is the straight line joining these two points.

© IIT ROORKEE NPTL ONLINE CERTIFICATION COURSE 11

The two straight lines are mirror images of each other, the upper line contains the two securities and risk return space and the portfolio possibilities curve in this region. If no short sales are allowed then what happens? Then the portfolio possibilities curve is constrained or is restricted to the line segment A B joining the two straight line segment line A B joining the points representing the two securities A and B in risk returns space.

Then we move over to the perfectly anti correlated assets for which rho is equal to minus 1 here again we have A situation where we have A pair of straight lines in the region that  $X_1$  is less than  $\sigma_B$  divided by  $\sigma_A$  plus  $\sigma_B$  the equation 26 will hold and in the region where  $x_1$  is greater than  $\sigma_B$  divided by  $\sigma_B$  plus  $\sigma_A$  equation 27 would hold.

(Refer Slide Time: 08:33)

**PERFECTLY ANTICORRELATED ASSETS  $\rho=-1$**

$$X_A < \frac{\sigma_B}{\sigma_B + \sigma_A}; y = \frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 + \sigma_2)} x + \frac{(\bar{R}_2 \sigma_1 + \bar{R}_1 \sigma_2)}{(\sigma_1 + \sigma_2)} \quad (26)$$

$$X_A > \frac{\sigma_B}{\sigma_B + \sigma_A}; y = -\frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 + \sigma_2)} x + \frac{(\bar{R}_2 \sigma_1 + \bar{R}_1 \sigma_2)}{(\sigma_1 + \sigma_2)} \quad (27)$$

12

Again you see that these are pair of straight lines which are mirror images of each other about A line which is parallel to x axis through the point of intersection of the two lines with the y axis indeed the y intercept of both these lines is the same point, so the two lines and let us call them B F and A F intersect the y axis at the same point which is given by the point F which represents the risk free asset.

(Refer Slide Time: 09:13)

Now, so this is the pictorial diagram of the case when rho is equal to minus 1 when the two securities are perfectly anti-correlated the portfolio possibilities curve represent is represented by

the pair of straight lines  $cf$  and  $ft$  where the region  $bc$  represents a situation where  $A$  is short and  $B$  is long, the region  $BFA$  or the portion of the two lines  $BF$  and  $af$  or  $fa$  represents the region where both  $A$  and  $B$  are long and then there is an  $A d$  represents where  $A$  is long and  $B$  is short.

The risk free rate is given by  $R_1 \sigma_2 + R_2 \sigma_1$  divided by  $\sigma_1 + \sigma_2$  and this lies between  $R_1$  and  $R_2$  this is the interesting part, this is the important distinction between the perfectly correlated and the perfectly anti-correlated cases in the end perfect correlated case the risk-free rate was outside the interval  $R_1$  and  $R_2$  here the risk-free rate lies between  $R_1$  and  $R_2$ .

So, this is the diagram pictorial representation of the case where  $\rho$  is equal to minus 1. So,  $A$  lies on  $ft$  that is the lower, lower, assuming that  $\sigma_A$  the security  $A$  has a lower standard deviation than security  $B$  lower return than security  $B$  then  $A$  lies on  $F d$  and  $B$  lies on  $fc$  and for the risk free rate as I mentioned there is free rate is given by  $R_1 \sigma_2 + R_2 \sigma_1$  divided by  $\sigma_1 + \sigma_2$  and this lies between the returns  $R_1$  and  $R_2$ . This risk free rate is obviously unique.

(Refer Slide Time: 10:48)

**CONCLUSION**

- Hence, any portfolio of two perfectly anti-correlated securities will be a pair of straight lines through a common Y-intercept. These are mirror images of each other. The upper line contains the one security and the lower contains the other one.
- The PPC, in this case. (if no short sales are allowed) is the pair of line segments AFB.

16

So, to conclude as far as the perfectly anti-correlated securities are concerned any portfolio of two perfectly anti-correlated securities will be a pair of straight lines through the common y intercept these are mirror images of each other and the upper one upper line contains one security and the lower line contains the other security. The portfolio possibilities curve if short sales are not allowed is the pair of line segments  $AF$  and  $FB$ .

(Refer Slide Time: 11:24)

### PPC FOR GENERAL $\rho$ (NO SHORT SALES)

- The exact shape of the hyperbola is parameterized by  $\rho$  between the two securities.
- The PPC shall be confined to the section of the hyperbola lying in the first quadrant between the lines:

17

$$y = \frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 + \sigma_2)}x + \frac{(\bar{R}_2\sigma_1 + \bar{R}_1\sigma_2)}{(\sigma_1 + \sigma_2)} \quad (26)$$

$$y = -\frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 + \sigma_2)}x + \frac{(\bar{R}_2\sigma_1 + \bar{R}_1\sigma_2)}{(\sigma_1 + \sigma_2)} \quad (27)$$

$$y = \frac{(\bar{R}_1 - \bar{R}_2)}{(\sigma_1 - \sigma_2)}x + \frac{(\bar{R}_2\sigma_1 - \bar{R}_1\sigma_2)}{(\sigma_1 - \sigma_2)} \quad (20)$$

These lines form a triangle with vertices

$$A(\sigma_1, \bar{R}_1), B(\sigma_2, \bar{R}_2), F\left(0, \frac{(\bar{R}_1\sigma_2 + \bar{R}_2\sigma_1)}{(\sigma_1 + \sigma_2)}\right)$$

18

For general A row when no short cells are allowed what happens the exact shape of the hyperbola it is A hyperbola as we have discussed earlier it the exact shape of the hyperbola is determined by the value of rho, the closer the value of rho is 2 plus 1 the lesser would be the bulge and the closer the value of rho two minus 1 the greater would be the bulge.

The portfolio possibilities curve shall be confined to the section of the hyperbola that lies in the first quadrant between the lines that is given by the equation number 26, 27 and 20 and these three equations or the lines represented by these three equations intersect at three points which are given by A which represents one security sigma 1 R1, the B which represents the other

security  $\sigma_2$  and the risk-free rate which represents which is represented by  $r_1 \sigma_2 + r_2 \sigma_1$  divided by  $\sigma_1 + \sigma_2$ .

Of course the x coordinate of F is 0 because it is the risk-free point or point representing the risk-free combination and by definition we assume that the standard deviation is A measure of risk and therefore risk free, risk freeness implies A zero value for the standard deviation.

(Refer Slide Time: 12:40)

So, this is the diagram of the general portfolio possibilities curve of two securities you can see that m is A point in between these two will come back to the characteristics of m but the basic thing is that the portfolio possibilities curve in the event that short sales are not allowed is restricted to the arc of the hyperbola AMB.

And if short sales are allowed then of course the portfolio possibilities curve would extend in either direction along this arc of the hyperbola beyond B as well as beyond A. So, if we extrapolate the arc of the hyperbola beyond B that would be the region where B is long as short and if you extrapolate the region, extrapolate the arc of the hyperbola beyond A and then it would be the region where A is long and B is short. Then we talked about the portfolio possibilities curve with short sales for allowed which I have just discussed in the case of two risky assets

Now, we move to the agenda for today, we start with A situation where we have two securities we have so far discussed the situation where we have two securities and both are risky securities so both of them have non-zero standard deviations. Now, we talk about the situation where one of the two securities let us say the security B is A risk-free security and because it is A risk-free security by definition or by the assumption that standard deviation is A measure of risk and because B is assumed to be risk free therefore  $\sigma_B$  must necessarily be 0. Furthermore because the risk-free asset has no correlation with any risky security it must also be that  $\rho$  would be 0 for any security A with the risk free security F, let us call the risk free security F, instead of B.

So, let the asset be renamed F where is free asset so that  $\sigma_2 = \rho = 0$  and  $R_2 = R_F$ ,  $R_F$  may not be 0 please note this point the risk free rate of return need not necessarily be 0 at all.

(Refer Slide Time: 15:05)

**THE PPC WITH ONE OF SECURITIES BEING RISKFREE**

- Let the asset B, renamed F be a riskfree asset so that  $\sigma_2 = \rho = 0$  and  $R_2 = R_F$ . Using the eqs.

$$\bar{R}_p = X_1 \bar{R}_1 + X_2 \bar{R}_2 \quad (9)$$

$$\sigma_p^2 = X_1^2 \sigma_1^2 + X_2^2 \sigma_2^2 + 2X_1 X_2 \rho \sigma_1 \sigma_2 \quad (10)$$

BY ROOKEE NPTEL ONLINE CERTIFICATION COURSE 21

$$\bar{R}_p = X_A \bar{R}_A + (1 - X_A) \bar{R}_F; \sigma_p = \pm X_A \sigma_A$$

$$\bar{R}_p = \frac{\bar{R}_A - \bar{R}_F}{\sigma_A} \sigma_p + \bar{R}_F \text{ when } X_A = \frac{\sigma_p}{\sigma_A} > 0 \quad (32)$$

$$\bar{R}_p = -\frac{\bar{R}_A - \bar{R}_F}{\sigma_A} \sigma_p + \bar{R}_F \text{ when } X_A = -\frac{\sigma_p}{\sigma_A} < 0 \quad (33)$$

So, in this case the standard portfolio equations become equation number 9 using equation number 9 and 10 we have the situation where these two equations on eliminating on the composition fraction  $X_A$  we get equations number 32 and 33. Equation number 32 would hold in the region where  $X_A$  is positive and equation number 33 would hold in the region where  $X_A$  is negative.

Furthermore, we can see that the security A, that is the risky security that we have lies on this the line represented by equation number 32 not on the line represented by equation number 33. Now, depending on the sign of  $R_A$  minus  $R_F$  it would determine whether which of these securities is upward sloping and which of these securities is downward sloping. If  $R_A$  is greater than  $R_F$  then what happens is that the equation 32 or the line represented by equation 32 would be upward sloping and the line represented by equation 33 would be downward sloping and the converse would be the case if  $R_A$  is less than  $R_F$ .

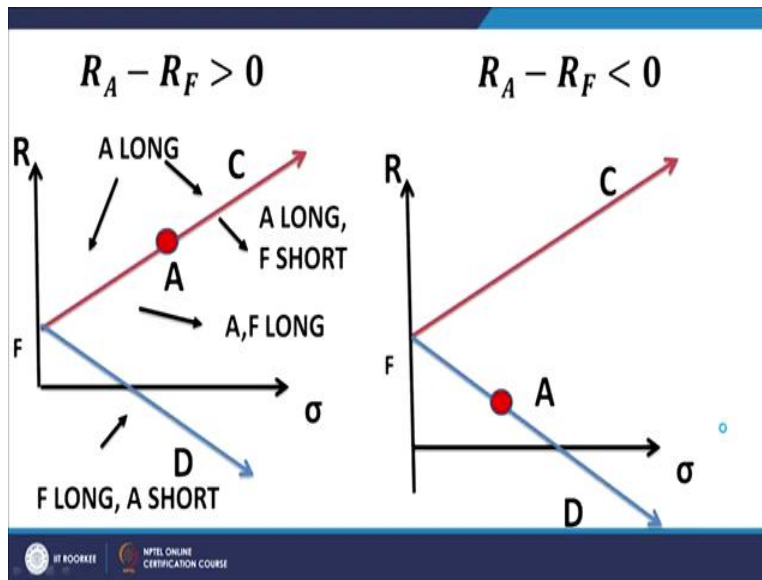

(Refer Slide Time: 16:18)

- These are a pair of straight lines that intersect each other and the  $Y$  axis at the point  $(0, R_F)$ .
- The security  $A$  lies on the line of eq (32).
- These lines are mirror images about a line parallel to  $X$ -axis through  $R_F$ .
- Since  $\sigma_P$  being standard deviation must necessarily be positive, we have the following situation:

So, this is A pair of straight lines which intersect each other at the and the y axis at the point 0 comma RF, so this is A I repeat these are straight lines it is quite obvious that these are straight lines and the y intercept of both the straight lines is RF so the both these lines intersect the y-axis and among themselves at the point 0 comma RF.

The security  $A$  lies on equation 32 I have already mentioned that the lines are mirror images of each other about A line parallel to the x-axis through RF because this slopes are inverse of each other since sigma P being standard deviation must necessarily be positive we have the following situation.

(Refer Slide Time: 16:59)

If  $R_A - R_F$  is positive and then what happens that the equation number 32 would be upward sloping and equation number 33 would be downward sloping and as I mentioned security A lies on the line represented by equation 32 and therefore we have the left hand side figure in out of this pair of figures and as far as identifying the and the portfolio composition along the various points of various segments represented in this figure AF region holds or the portfolio would lie in the region AF if both A and F are long.

In other words we have risk-free lending coupled with investment in the security A along AC the security A remains long whereas we have risk free borrowing and along FD we have risk free lending at the cost of being short in securities. So, you are short selling security A and you are investing the proceeds in the risk-free asset that is represented by the section FT extended of course.

And if  $R_A - R_F$  we have the opposite situation as depicted in the second figure or the right hand side figure on this slide. So, in the region A F both A and F are long let me repeat both A and F and longer in the region af along ac extended indefinitely A is long F is short; F is short means we have risk free borrowing and along F d extended we have A is short and F is long in other words we have, we are short selling A and doing risk free landing.

(Refer Slide Time: 19:03)

- Let  $R_A - R_F > 0$  hold. Then
- The slope of eq (32) is positive so that FA is upward sloping.
- In the region FA both F & A are long. Beyond A, F is short.
- The lower line FD represents F long and A short. At F,  $X_F=1$  and  $X_A=0$ . Beyond F along FD, A becomes short.
- If  $R_A - R_F < 0$  holds, converse will be the case.

MIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

So, this is the description of that figure, the slope of equation 32 is positive so that fa is upward sloping as you saw in the diagram. In the region F F A both F and A are long beyond A F is short and the lower line represents F long and A short as I mentioned at F x F is x F is equal to 1; x A is equal to 0 beyond F and along fd A becomes short. If  $R_A$  minus  $R_F$  is less than 0 the converse will be the case as represented in the right hand side figure on the previous slide.

(Refer Slide Time: 19:28)

### THE PPC WITH TWO RISKY SECURITIES AND A RISKFREE SECURITY

- Let  $A(\sigma_1, R_1)$  &  $B(\sigma_2, R_2)$  be two risky securities and  $F(0, R_F)$  be a riskfree security.

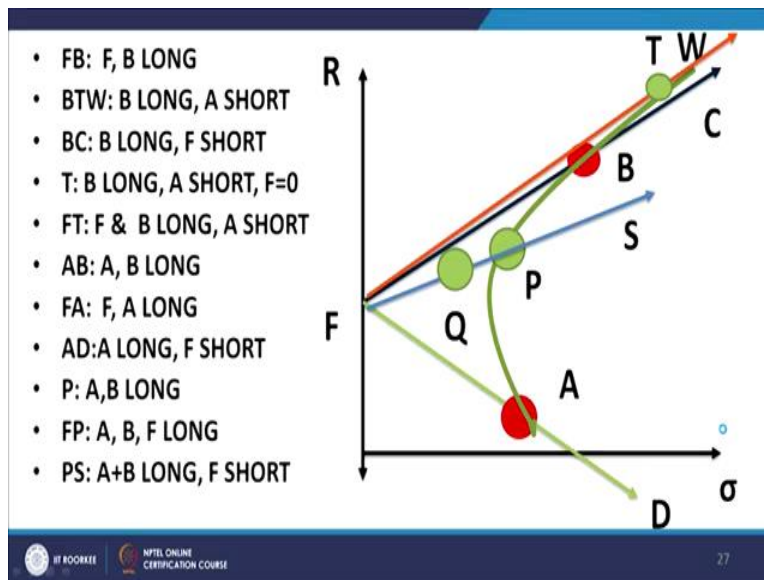

MIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 26

Now, we come to the nuances of portfolio so far we have been addressing the foundations of portfolio optimization or rather the shape and structure of the portfolio possibilities curve in

rather simple simplistic situations we now get into the nuances of this theory. We now consider the portfolio possibilities curve or the portfolio possibilities region as you will soon find it to be with two risky securities and A risk-free security.

So, let  $A$   $\sigma_1$   $R_1$  be and  $B$   $\sigma_2$   $R_2$  be two risky securities and  $F$   $0$  comma  $R_F$  be the risk-free securities. Please note we are now considering the case where we have two risky securities and A risk-free security; two risky securities and A registry security and  $A$   $\sigma_1$   $R_1$   $B$   $\sigma_2$   $R_2$  are the two risky securities and  $F$   $0$  comma  $R_F$  is the risk free security,  $R_F$  is obviously the risk free rate of return. And this is the diagram which emanates when we you can see the complexity relative to the diagrams that we have observed earlier but I will explain each and every segment of this, this will take some time but let us start going through it.

(Refer Slide Time: 20:50)

A and B obviously represent the two securities and F represents that is free asset, risk free securities please note we are having A situation where rho can be take and can take any values within minus 1 and plus 1 with excluding minus 1 and plus 1 because we have already discussed the cases of the two securities being perfectly correlated and perfectly anti-correlated.

So, in the region F B if you look at F B, now let me first explain this B C is the extension of F B, F B is the straight line joining F B and this is being extended along C. Now B T W; B T W is the extension of the hyperbolic arc that joins A and B. So, A P B T W is the arc of the hyperbola as

far as  $d_A$  is concerned it is the extension of straight line  $FA$ , so  $FA d$  is a straight line,  $P$  is an arbitrary point on  $AB$ .

$S$  is an arbitrary point on  $fb$  extended and  $Q$  is an arbitrary point which lies between  $P$  and  $F$ . So, this is the description of the various symbols that we have on the slide. Now let us see what each of these lines and the symbols represent. So, as far as  $FB$  is concerned it is quite obvious that it has to be a linear combination of securities  $F$  and  $B$  with both securities being long,  $x_F$  and  $x_B$  will both be between 0 and 1 in the region  $FB$ .

Now, what about  $BTW$ ? Along  $BTW$ ,  $BTW$  is the extension of  $AB$  along the arc of the hyperbola  $APB$  this continues onwards to  $TW$ . Therefore, because  $T$  and  $W$  lie on this arc of the hyperbola they will be combinations of  $A$  and  $B$  only. In fact beyond  $B$  if you go along  $BTW$  then  $B$  becomes longer  $B$  continues to be long but  $A$  starts becoming short at the point  $B$ ;  $x_B$  is equal to 1;  $x_A$  is equal to 0 and there is of course no  $x_F$ .

But as you move along  $BTW$ ; along  $BTW$  along the hyperbolic arc I reiterate then it  $x_A$  starts becoming short,  $x_B$  continues to be long with being greater than 1  $x_B$  being greater than 1 but  $x_F$  continues to be 0 because there is no involvement of  $F$  in so far as this hyperbolic arc is concerned. In other words I will come back to it except for the point  $T$ , there would be no point on this arc  $AB$  and even at the point  $T$  of course there be no point here where  $x_F$  would be having a positive or negative value other than 0 along the arc of the hyperbola  $ABTW$ .

So,  $BTW$  represents  $B$  long and  $A$  short;  $BC$  now  $BC$  is what?  $BC$  is the extension of the straight line joining  $FP$ , so at the point  $F$  we have  $x_F$  equal to 1,  $x_B$  equal to 0; at the point  $B$  we have  $x_B$  equal to 1,  $x_F$  equal to 0 and if you move along the same straight line to along  $BC$  then  $x_B$  becomes greater than 1 and  $x_F$  becomes less than 0 which means that we are having risk-free borrowing.

So, what you are doing is along  $bc$  you are borrowing risk-free and you are investing in this security  $B$ . Then at the point  $T$ , what is the point  $T$ ? First let me explain the point  $T$  is the point at which with the tangent is drawn from the point  $F$  tangent is drawn from the point  $F$  to the hyperbolic arc  $AB$  extended if required. I repeat  $T$  is the point at which we draw a tangent from the point  $F$  to the hyperbolic arc  $AB$  extended.

So, at the point T, FT is tangent to the arc ABTW. So, at the point T we have A long because it lies on the hyperbola AB so we have A long we have B I am sorry we have A short, we have A short we have B long and we have no involvement of risk-free lending or borrowing but beyond T if you go along the straight line FT beyond T then short risk free borrowing starts and then you have risk free borrowing together with the long position in B and the short position in A.

So, you have short positions in F and short position in A and A long position in B if you move along FT straight line extended. Where FT is the tangent I repeat FT is the tangent to the hyperbolic arc AB extended. So, FT, F and B long along the line FT of course what will you have; you will have you see now please note this interesting point along the line FT what will you have? You will have linear combination of F and T, at the point F,  $x_F$  is 1;  $x_T$  is equal to 0, at the point T;  $x_F$  is 0,  $x_T$  is equal to 1.

But what is  $x_T$ ?  $x_T$  is  $x_T$  lies on the arc of the hyperbola AB therefore it must be A combination of A and B with because it is extended beyond B that means  $x_B$  and  $x_A$  would be in such A proportion that  $x_B$  is long and  $x_A$  is short. So, along FT up to T F and B are long and A is short and what about AB? I have already discussed AB is the arc of the hyperbola and at any point along the hyperbolic arc we shall have A and B together either A long or B long or one of them long and one of them short.

But within A and B, along the arc B within A and B there would be no short sales and both A and B would be long. If you extend beyond B along the arc then B becomes A long A becomes short if you go beyond A along the arc then A becomes long B becomes short. So, what about FA; FA is the straight line where it is A linear combination of A and F so obviously in the segment FA, A is long F is also long in other words you have A combination of risk-free lending and investment in security.

But if you move beyond A along AD then what happens then A becomes continues to be long but F becomes short in other words you have risk-free borrowing and the investment of the borrowed proceeds in security A. AD I have discussed the what about the point P, now this is interesting, point B is an arbitrary point between A and B along the arc A and B I repeat point P

is an arbitrary point along A B within A and B that is along the arc AB and it lies somewhere within A and B.

So, it must be A combination of securities A and B with both securities being long. Now, what about F P? F P is A straight line which is bounded by F and P so it has to be A linear combination of the portfolios represented by F and P that means at the point F obviously we have  $x_F$  equal to 1,  $x_P$  equal to 0 at the point P we have  $x_P$  equal to 1  $x_F$  equal to 0 and if you take any arbitrary point Q in between F and P then it would be A linear combination of F and P.

But P itself is A combination of securities A and B both long therefore at any point Q which lies between F and P both or all the three securities F A and B would be long and please note this is any arbitrary point within the region B F A bounded by the lines line segments BF bounded by the line segment AF and bounded by the arc A B.

So, if you take any point bounded by these three points A, F, F B and the arc A B then you have A combination where all the three securities would be long. So, this region of space lying between F A, F B and the arc A B will represent combinations where all the three securities are long. Now, what about the point is S? S is the point outside the arc towards the right of the arc A B.

Now, obviously at point P we have  $x_P$  equal to 1,  $x_F$  equal to 0 but if you move along F P beyond P then what happens is that  $x_F$  becomes negative  $x_P$  becomes greater than 1 so the point S represents the risk-free borrowing and the investment of the proceeds in the combination represented by the point P. So, at the point P what do we have? I am sorry at the point S what do we have?

We have short in F and long and the securities A and B. So, I have discussed almost all these regions and all these positions of various points on this diagram it is very interesting and it will help us in understanding what is to follow from here on.

Now we can have different scenarios as I explained in the diagram previously we have different situations where one security can be long, the other can be short or two can be long and the third can be shorter all three can be long so on that basis I have classified the portfolio composition into different scenarios we have six scenarios here.

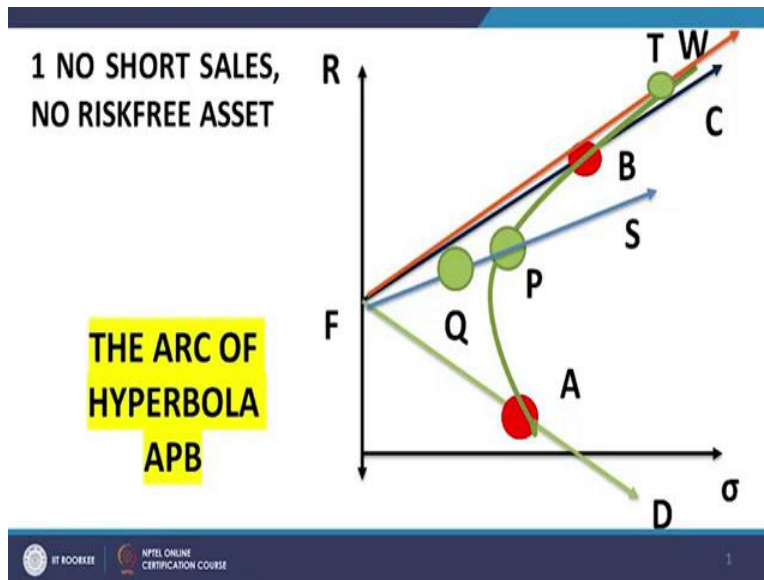

(Refer Slide Time: 31:35)

| <b>DIFFERENT SCENARIOS</b> |                 |                  |
|----------------------------|-----------------|------------------|
| <b>• RISKY ASSETS A,B</b>  | <b>RISKFREE</b> | <b>RISKFREE</b>  |
| <b>•</b>                   | <b>LENDING</b>  | <b>BORROWING</b> |
| <b>• NO SHORT SALES</b>    | <b>NO</b>       | <b>NO</b>        |
| <b>• SHORT SALES</b>       | <b>NO</b>       | <b>NO</b>        |
| <b>• NO SHORT SALES</b>    | <b>YES</b>      | <b>NO</b>        |
| <b>• NO SHORT SALES</b>    | <b>YES</b>      | <b>YES</b>       |
| <b>• SHORT SALES</b>       | <b>YES</b>      | <b>NO</b>        |
| <b>• SHORT SALES</b>       | <b>YES</b>      | <b>YES</b>       |

First of all, we have A situation where no short sales are allowed in A and B and there is no risk-free lending or borrowing then we have short sales in A and B but no risk-free lending and borrowing. Then we have no short sales in A and B but we do have risk free lending; then we have no short sales in A and B but we do have this free lending and borrowing then short sales with risk free lending but no borrowing and then finally the most general situation where we have short sales allowed as well as risk free lending and borrowing allowed.

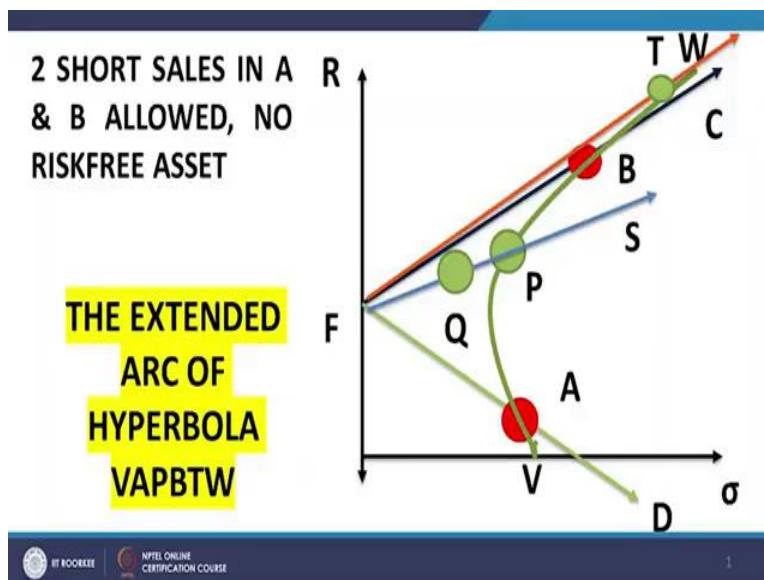

So, let us take the first case now. In the first case we have no short sales allowed no risk-free asset as I mentioned earlier in this case the portfolio possibilities curve we have discussed in it in A lot of detail it will be the arc of the hyperbola confined between the points A and B. So, I repeat in this situation where there are no short sales in A and B and no risk-free asset is there that means there is no risk-free lending, there is no risk-free borrowing in that situation the point representing the portfolio will lie on the arc A and B.

(Refer Slide Time: 32:40)

For example, the point P is a typical point where we have combination of A and B both long with no involvement of the risk-free asset F. So, in the case of no short sales with no risk-free asset lending or borrowing either case we the portfolio possibilities curve is the arc of the hyperbola lying between the two securities A and B.

(Refer Slide Time: 33:15)

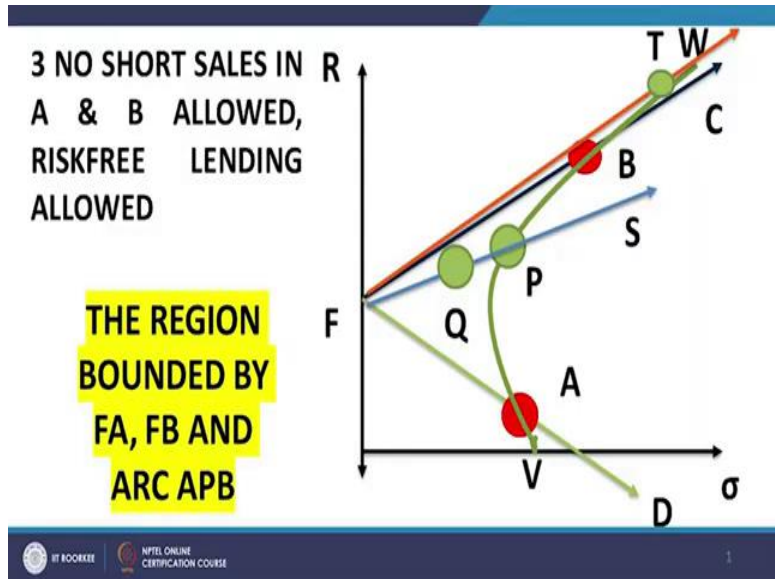

Then we move to case 2; in case 2 what do we have? Short sales in A and B are allowed but again we do not have A risk free lending that means no risk-free lending no risk-free borrowing

but we do have short sales in A and B allowed. In this case what happens is the portfolio possibilities curve gets extended along the arc of the hyperbola beyond A and beyond B as well.

So, in other words the entire arc of the hyperbola A B extended in both sides extended beyond A along the arc of the hyperbola and extended beyond B as well along the arc of the hyperbola will form the portfolio possibilities curve. If you take a point beyond B on the arc of the hyperbola A B it will represent B long and A short and if you take any point beyond A along the arc of the hyperbola you will find it to be A long and B short. And of course, along A B, along the arc in the region A B both A and B would be long. Now, we take the next situation, where no short sales in A and B are allowed but risk-free lending is allowed. In this case what happens is I have explained briefly this situation the portfolio possibilities region you know this is not a curve it is a region of space.

(Refer Slide Time: 34:30)

If the region of space is the space which is bounded by the straight lines or line segments BF or F P F A and the arc of the hyperbola A B, so this region which is bounded by these three to this pair of straight lines and the arc A B constitutes the feasible region constitutes the portfolio possibilities region in A situation where A neither any short sales are allowed nor risk-free borrowing is allowed but this will lending is allowed.

For example if you take any arbitrary point Q here, Q is A linear combination of F and P and P itself is A combination of A and B both being long please note because P lies between A and B

therefore P is A combination of both A and B, both being long. Because Q lies in between F and P both F and P are long in Q and P is long in A and B so the net result is that for Q being any arbitrary point between B F A the three securities all the three securities would be long. We shall continue from here after the break. Thank you.
