Gauss 2-point Rule: Construction

Our today's topic is Gaussian integration. So far, when we considered numerical integration rules, what we did were, we fixed the interpolation points. So, we started with interpolation points x_0, x_1, \dots, x_n .

We fitted an interpolating polynomial and then integration of that interpolating polynomial that was approximation to $\int_a^b f(x) dx$. Now today, what we are going to do is, we will not fix the interpolation points before hand. We will try to write an interpolation formula of the form, $\sum w_i f(x_i)$ where w_i 's are the bits and x_i 's are the interpolation point.

So, we are going to have, i going from 0 to n . So, in total we have got $2n + 2$ constants to be determined. Now these we will try to determine, so that, there is no error for polynomials of degree less than or equal to $2n + 1$.

(Refer Slide Time: 01:47)

$$\text{Fix } x_0, x_1, \dots, x_n \in [a, b]$$

$$p_n(x) = \sum_{i=0}^n f(x_i) l_i(x)$$

$$l_i(x) = \prod_{\substack{j=0 \\ j \neq i}}^n \frac{(x - x_j)}{(x_i - x_j)} : \text{Lagrange poly.}$$

$$\int_a^b f(x) dx \simeq \int_a^b p_n(x) dx$$

$$= \sum_{i=0}^n f(x_i) \int_a^b l_i(x) dx$$

$$= \sum_{i=0}^n f(x_i) w_i$$

\downarrow
 real nos.
 ind. of f .

So, that is the idea of Gauss integration. So, when we fix points x_0, x_1, \dots, x_n in the interval a, b and look at $p_n(x)$ to be equal to summation $f(x_i) l_i(x)$ where i goes from 0 to n where l_i is the Lagrange polynomial. So, it is product j goes from 0 to n $x_i - x_j$ divided by $x_i - x_j$, j not equal to i ; this is Lagrange polynomial.

Then integral a to b $f(x) dx$ is approximately equal to integral a to b $p_n(x) dx$ which will be equal to summation i goes from 0 to n $f(x_i) \int_a^b l_i(x) dx$.

Now, what you have to note is that $l_i(x)$ the Lagrange polynomial, it depends only on the interpolation points x_0, x_1, \dots, x_n . So, there is no function f coming in to picture there; it is a polynomial of degree n .

So, you can integrate. So, you integrate and then you are going to get the weights w_i . So, we have this to be equal to summation i goes from 0 to n $f(x_i) w_i$. So, these are real numbers independent of our function f . Now this is going to be our starting point.

So, let us start with a formula integral a to b $f(x) dx$ is approximately equal to summation $w_i f(x_i)$, i goes from 0 to n .

(Refer Slide Time: 03:57)

$$\int_a^b f(x) dx \approx w_0 f(x_0) \quad w_0, x_0: \text{unknowns.}$$

$$f(x)=1 : \text{No error.}$$

$$\int_a^b dx = w_0 \Rightarrow w_0 = b-a$$

$$f(x)=x : \text{No error}$$

$$\int_a^b x dx = w_0 x_0 \Rightarrow \frac{b^2-a^2}{2} = (b-a)x_0$$

$$\Rightarrow x_0 = \frac{a+b}{2}$$

$$\int_a^b f(x) dx \approx (b-a) f\left(\frac{a+b}{2}\right) : \text{exact for linear polynomials.}$$

\swarrow
Midpoint Rule.

So, our starting point is integral a to b f x d x is approximately equal to summation i goes from 0 to n w i f x i and we want to determine x i's and w i's, such that integral a to b f x d x is equal to summation w i f x i, i goes from 0 to n for polynomials of degree less than or equal to 2 n plus 1.

So, we want that there should not be any error, if our function f is a polynomial of degree 2 n plus 1. This can be achieved provided there is no error for functions 1 x, x square, up to x raise to 2 n plus 1 because any polynomial of degree 2 n plus 1 is going to be combination of this functions 1 x, x square, x raise to 2 n plus 1.

So, now put f x is equal to 1 and then equate an integral a to b 1 d x is equal to summation w i f x i, i goes from 0 to n. So, f x is 1. So, that will give us one equation and like that you will have 2 n plus 2 equations because there will be f x is equal to 1 then x, x square up to x raise to 2 n plus 1 and then our unknowns are also 2 n plus 2 in number; the unknowns are going to be the weights w 0 w 1 w n and x 0 x 1 x i. So, we have got 2 n plus 2 equations into n plus 2 unknowns.

So, let us look at some special cases. So, suppose we are taking n is equal to 0; that means, we have got x 0 is 1 point and w 0 is the weight.

We want $\int_a^b f(x) dx$, is equal to $w_0 f(x_0)$ if f is a polynomial of degree 1 which we mean that once take function $f(x)$ is equal to 1 then take $f(x)$ is equal to x , you will get 2 equations and from that we will try to determine w_0 and x_0 .

So, let us do that. So, we have $\int_a^b f(x) dx$ is approximately equal to $w_0 f(x_0)$, w_0 and x_0 these are unknowns.

$f(x)$ is equal to 1 constant function; we want that there is no error.

That means $\int_a^b dx$ should be exactly equal to w_0 of $f(x_0)$.

$f(x)$ is 1, so that means, it is equal to w_0 .

So, this imposes the condition that w_0 should be equal to $b - a$. So, which means that if I choose w_0 to be equal to $b - a$ and x_0 to be any point in the interval a, b , then the formula $w_0 f(x_0)$ is going to be exact for constant polynomials.

So, now we want our formula to be exact for linear polynomials. So, we will impose one more condition for $f(x)$ is equal to x . So, w_0 we have already determined the condition $f(x)$ is equal to x that will determine our point x_0 .

So, we have $f(x)$ is equal to x ; in this case also no error that will happen, provided $\int_a^b x dx$ is equal to $w_0 x_0$, which will imply $b^2 - a^2$ by 2 which is the $\int_a^b x dx$ should be equal to w_0 is $b - a$ multiplied by x_0 .

So, this means x_0 should be equal to midpoint $a + b$ by two. So thus, $\int_a^b f(x) dx$ if you approximate it by $b - a$ into f of $a + b$ by 2 this is going to be exact for linear polynomials.

And this is nothing, but the midpoint rule. So thus, we have solved a problem for case n is equal to 0. Now let us look at the case n is equal to 1.

So, when you put n is equal to 1 you are trying to approximate $\int_a^b f(x) dx$ by a formula of the type $w_0 f(x_0) + w_1 f(x_1)$, unknowns w_0, w_1, x_0, x_1 we will like to determine in such a manner that now our rule is exact for polynomials of degree less than or equal to 3.

This will be achieved provided there is no error for 4 functions which are 1 x, x square x cube any cubic polynomial is going to be of the form a 0.

Plus a 1 x plus a 2 x square plus a 3 x cube. So, if there is no error for the 4 functions 1 x, x square, x cube there will not be any error for a cubic polynomial a general cubic polynomial.

(Refer Slide Time: 11:09)

Handwritten mathematical derivation on a whiteboard:

$$\int_a^b f(x) dx \approx w_0 f(x_0) + w_1 f(x_1)$$

$$f(x) = 1 : b - a = w_0 + w_1 \quad \dots \textcircled{1}$$

$$f(x) = x : \frac{b^2 - a^2}{2} = w_0 x_0 + w_1 x_1 \quad \dots \textcircled{2}$$

$$f(x) = x^2 : \frac{b^3 - a^3}{3} = w_0 x_0^2 + w_1 x_1^2 \quad \dots \textcircled{3}$$

$$f(x) = x^3 : \frac{b^4 - a^4}{4} = w_0 x_0^3 + w_1 x_1^3 \quad \dots \textcircled{4}$$

4 eq^s in 4 unknowns,
 w_0, w_1, x_0, x_1

NPTTEL

So, let us equate and get the 4 equations. So, we have integral a to b f x d x is approximately equal to w 0 f x 0 plus w 1 f x 1. First put f x is equal to 1 then we want b minus a should be equal to w 0 plus w 1.

So, that is the first condition. Then f x is equal to x. So, that is going to be b square minus a square by 2 it is the integral a to b x d x and on the right hand side it is going to be w 0 x 0 plus w 1 x 1. Next look at the function f x is equal to x square, its integral is x cube by 3. So, this is going to be b cube minus a cube by 3, on the right hand side it will be w 0 x 0 square plus w 1 x 1 square and f x is equal to x cube that will be b raise to 4 minus a raise to 4 divided by 4 is equal to w 0 x 0 cube plus w 1 x 1 cube. So, let me call these 4 equations 1 2 3 4.

So, we have got 4 equations in 4 unknowns, which are w 0 w 1 x 0 x 1. Now these 4 equations, we got 4 equations in 4 unknowns, but these are non-linear equations if they were linear equations then solving them is easy, but we have got 4 non-linear equations.

Now, in this particular case one can do some manipulation and one can try to find w_0 w_1 x_0 x_1 , but what we want is we want to look at a general case that when you are considering a formula of the type summation i goes from 0 to n $w_i f(x_i)$.

How I should choose the weights w_i 's and the interpolation points x_i 's in such a manner that I have no error for as high degree polynomial as possible.

So, that is why we will not do manipulation for this, but look at a general case. Now for the general case, the method which we are going to use, I am going to explain again for this particular case n is equal to 1 and then we will see how to generalize.

So, the first thing we are going to do is, we are going to obtain the conditions on x_0 x_1 which will guarantee that if you interpolate, if you choose x_0 x_1 in a certain manner, fit a linear polynomial, integrate then the formula which you are going to get it will be exact for cubic polynomial.

So, let us derive the condition which the interpolation points x_0 and x_1 should satisfy. Once we find this condition there are going to be 2 conditions; then we will see, how to choose x_0 and x_1 .

So, that these conditions are satisfied. So, first we are finding the conditions which the interpolation points x_0 and x_1 should satisfy and then find the points x_0 x_1 which satisfy this condition.

So, let us look at 2 points x_0 and x_1 , fit a linear polynomial no matter how you choose your 2 points x_0 and x_1 if you fit a linear polynomial then the interpolating polynomial is same as the function if the function is a linear polynomial. So, there will not be any error in our integration formula for linear polynomials, but we want something more we want that the error should not be there or error should be equal to 0 for cubic polynomial.

(Refer Slide Time: 16:10)

$$f(x) = f(x_0) + f[x_0, x_1](x-x_0) + f[x_0, x_1, x] \frac{(x-x_0)(x-x_1)}{\omega(x)}$$

$$\int_a^b f(x) dx = \int_a^b p_1(x) dx + \int_a^b f[x_0, x_1, x] \frac{(x-x_0)(x-x_1)}{\omega(x)} dx$$

error in the integration.

error =

y_0 : fixed point

$$f[x_0, x_1, x] = \frac{f[y_0, x_0, x_1] + f[y_0, x_0, x_1, x](x-y_0)}{\omega(x)}$$

$$\text{error} = f[y_0, x_0, x_1] \int_a^b \omega(x) dx + \int_a^b f[y_0, x_0, x_1, x](x-y_0) \omega(x) dx$$

So, we have $f(x)$ is equal to $f(x_0)$ plus divided difference based on x_0, x_1 into $x - x_0$ and then you have got error term $f[x_0, x_1, x]$ multiplied by $(x - x_0)(x - x_1)$.

So, this is our polynomial $p_1(x)$ and this is our error and hence $\int_a^b f(x) dx$ will be equal to $\int_a^b p_1(x) dx$ plus $\int_a^b f[x_0, x_1, x] \frac{(x-x_0)(x-x_1)}{\omega(x)} dx$. So, this is going to be the error in the integration. Now we have used this technique beforehand. If your points x_0, x_1 are such that $\int_a^b \omega(x) dx = 0$ and $\int_a^b (x-y_0)\omega(x) dx = 0$.

Then we will like to make use of this relation, in order to manage our error we had done this for the midpoint rule; in the case of midpoint rule we had $\int_a^b \omega(x) dx = 0$ plus $b - a$ by 2 $\int_a^b (x - \frac{a+b}{2}) \omega(x) dx = 0$. So, our error formula has got 2 parts; it has got a divided difference and then you are multiplying by the function $w(x)$. So, this divided difference in the error formula it depends on x . So, we cannot take it out of the integration sign.

But if I replace this divided difference which is based on x by a divided difference which is independent of x and then plus extra term then I can take the divided difference out. So, let us look at the error.

And then $f[x_0, x_1, x]$ this divided difference, let me write it as $f[y_0, x_0, x_1] + f[y_0, x_0, x_1, x](x - y_0)$ multiplied by $(x - x_0)(x - x_1)$; this is the recurrence relation this you take on the other side divide by $(x - y_0)$ that is the recurrence formula for $f[y_0, x_0, x_1, x]$.

So, this I am going to substitute here; now here y_0 is a fix point. So, that will come out of the integration sign and our error will be equal to $f(y_0) \int_a^b \omega(x) dx$ plus $\int_a^b f(y_0, x_0, x_1, x) \omega(x) (x - y_0) dx$ where I am calling this as $w(x)$. So, if this is equal to 0 then our error is going to have this form.

(Refer Slide Time: 20:25)

The whiteboard shows the following derivation:

$$\text{If } \int_a^b \omega(x) dx = 0, \text{ then}$$

$$\text{error} = \int_a^b f[y_0, x_0, x_1, x] \omega(x) (x - y_0) dx$$

$$f[y_0, x_0, x_1, x] = f[y_1, y_0, x_0, x_1] + f[y_1, y_0, x_0, x_1] (x - y_1) \quad \left| \begin{array}{l} \text{Recurrence} \\ \text{relation} \end{array} \right.$$

$$\text{error} = f[y_1, y_0, x_0, x_1] \int_a^b \omega(x) (x - y_0) dx + \int_a^b f[y_1, y_0, x_0, x_1] (x - y_1) (x - y_0) \omega(x) dx$$

The NPTEL logo is visible in the bottom left corner of the whiteboard image.

If $\int_a^b \omega(x) dx$ is equal to 0 then error is equal to $\int_a^b f(y_0, x_0, x_1, x) \omega(x) (x - y_0) dx$.

So, now look at the error; error has a divided difference based on 4 points that is $f(y_0, x_0, x_1, x)$ if your function f is a quadratic polynomial then this divided difference will be 0 and that means, error will be 0. So, if our points x_0 and x_1 , if they are such that $\int_a^b \omega(x) dx$ is equal to 0 then we get the formula to be exact for quadratic polynomial. So, earlier we had only exactitude for linear polynomials, now we got for quadratic polynomial with 1 condition $\int_a^b \omega(x) dx = 0$. Now we will use the same technique again and then obtain another condition which will give us the error to be 0 for cubic polynomials.

So, now let us write down the divided difference $f(y_1, y_0, x_0, x_1)$ has $f(y_1, y_0, x_0, x_1) - f(y_1, y_0, x_0, x_1) (x - y_1)$. So, this is the recurrence relation; this we substitute in the error. So, we will get error to be equal to $f(y_1, y_0, x_0, x_1) \int_a^b \omega(x) (x - y_0) dx$ plus, here it should be plus not minus, plus $\int_a^b f(y_1, y_0, x_0, x_1) (x - y_1) (x - y_0) \omega(x) dx$.

to b of y_1, y_0, x_0, x_1, x , x minus y_1 then we have got this $w(x) = (x - y_0)(x - y_1)$. So, it will be x minus y_0 $w(x) dx$.

Now, if this is equal to 0 then this will be the expression for the error. If $\int_a^b w(x) dx = 0$ and $\int_a^b w(x)(x - y_0) dx = 0$. If both the conditions are satisfied our error is integral a to b divided difference based on 5 points the points are the divided difference is based on y_1, y_0, x_0, x_1 and x . So, we have got 5 points.

If f is a polynomial of degree 3 then this divided difference will be equal to 0. So, our error is integral a to b , a divided difference multiplied by $w(x)$ into x minus y_0 x minus y_1 dx if the divided difference term is 0 error is going to be equal to 0.

So, thus we obtain 2 conditions, which guarantee that there is no error for cubic polynomials and those 2 conditions are $\int_a^b w(x) dx = 0$ and $\int_a^b w(x)(x - y_0) dx = 0$.

(Refer Slide Time: 25:03)

$w(x) = (x - x_0)(x - x_1)$
 $\int_a^b w(x) dx = 0, \int_a^b w(x)(x - y_0) dx = 0$
 $\Rightarrow \text{error} = \int_a^b f[x_1, y_0, x_0, x_1, x] w(x)(x - y_0)(x - y_1) dx$
 $= 0$ if f : cubic poly.
 $\Rightarrow \text{error} = 0$ if f is a poly. of degree ≤ 3 .
 Conditions: $\int_a^b w(x) dx = 0, \int_a^b w(x) \cdot x dx = 0$.
 $y_0 = x_0, y_1 = x_1$
 $\text{error} = \int_a^b f[x_0, x_0, x_1, x_1, x] (x - x_0)^2 (x - x_1)^2 dx$.

We have $w(x) = (x - x_0)(x - x_1)$ $\int_a^b w(x) dx = 0$ $\int_a^b w(x)(x - y_0) dx = 0$ implies that the error is integral a to b $f[x_1, y_0, x_0, x_1, x]$ multiplied by $w(x)$ into x minus y_0 x minus y_1 dx and this term is equal to 0 if f is a cubic polynomial.

So, this means error is equal to 0 if f is a polynomial of degree, less than or equal to 3. Now, look at the condition $\int_a^b w(x) y_0 dx = 0$ is a fixed point and we already have $\int_a^b w(x) dx = 0$.

So that means, this condition will reduce to $\int_a^b w(x) dx = 0$. So, the conditions which we get are $\int_a^b w(x) dx = 0$ and $\int_a^b w(x) x dx = 0$.

So, we have to choose x_0 and x_1 such that these 2 conditions are satisfied and then for the error our y_0 and y_1 they can be any points in the interval a, b . So, we can choose our y_0 to be equal to x_0 y_1 is equal to x_1 and we will get $\int_a^b f(x) dx$ repeated twice x_1 repeated twice $x_0^2 - x_1^2 dx$.

Now, the reason for writing in this manner will be; now we have got a divided difference which is going to be continuous provided your function f is sufficiently differentiable, your multiplying by a function $x - x_0^2 - x_1^2$. So, this function is always bigger than or equal to 0. So, we can apply mean value theorem for integrals and then the divided difference we can take it out as divided difference based on x_0 repeated twice x_1 repeated twice and some point c , multiplied by $\int_a^b x - x_0^2 - x_1^2 dx$.

We can integrate this and then obtain a more precise bound as compare to, if we had dominated the $x - x_0$ and $x - x_1$ by $b - a$. So, now, our problem is we have reduced our problem to finding x_0 and x_1 such that $x - x_0 - x_1$ its integral is 0 and if you multiply $x - x_0 - x_1$ by x .

Then that integral also should be 0 now as I said we want to have a general method; that means, here we have taken only n is equal to 1. So, we have got 2 interpolation points x_0 and x_1 , but whatever we want to do we want to do it that, you should be able to extend it for the more general case like when you have got $n + 1$ points then how I should choose my $n + 1$ points

So, that we have got exactitude for polynomials of degree less than or equal to $2n + 1$. So, in order to do that what we are going to do is we are going to recall what is the inner

product. So, on our space C and D it is the vector space of continuous real valued functions defined on interval a, b , on this we will define an inner product as $\int_a^b f(x)g(x)dx$ once we have an inner product we can talk of 2 functions being perpendicular.

So, if the inner product is equal to 0 we say that f is perpendicular to g look at our condition which we want; it is $\int_a^b f(x) \cdot 0 \cdot dx$ should be equal to 0; that means, we want our function $w(x)$ to be perpendicular to the constant function 1 and second condition tells us that our $w(x)$ should be perpendicular to the function $f(x) = x$.

So, we will start with 3 functions function constant 1 then x and then x^2 to this we will apply Gram-Schmidt orthonormalisation process and get a quadratic polynomial which is perpendicular to constant function 1 and function x ; this quadratic polynomial, look at the roots of this, if the roots are $x=0$ and $x=1$ those are going to be our desired point and what we will do is inner product we will define on $C[a, b]$, but in order to find the points $x=0$ and $x=1$.

We will first consider the interval -1 to 1 and then we will look at a map from -1 to 1 to the interval a, b which is 1 to 1 on to n a fine and using this map we will transfer the results to interval a, b . So, let us look at the inner product on $C[a, b]$.

(Refer Slide Time: 32:04)

$C[a, b], f, g \in C[a, b]$
 $\langle f, g \rangle = \int_a^b f(x)g(x)dx$. Inner Product
 1) $\langle f, f \rangle \geq 0$, $\langle f, g \rangle = 0 \Leftrightarrow f(x) \equiv 0$
 $\int_a^b f^2(x)dx = 0$, $f^2: \text{cont}^2, f^2(x) \geq 0$
 $\Rightarrow f(x) \equiv 0$
 2) $\langle f, g \rangle = \langle g, f \rangle$: Symmetry
 3) $\langle f_1 + f_2, g \rangle = \langle f_1, g \rangle + \langle f_2, g \rangle$
 $\langle \alpha f, g \rangle = \alpha \langle f, g \rangle$, $\alpha \in \mathbb{R}$,
 $f_1, f_2 \in C[a, b]$

So, the vector space is $C[a, b]$, f and g these are functions in $C[a, b]$ inner product f comma g is $\int_a^b f(x)g(x) dx$.

So, this is inner product; its properties are inner product of f with itself is going to be bigger than or equal to 0 because we will be looking at $\int_a^b f^2(x) dx$ f is a real valued function then f comma f is equal to 0 if and only if the function $f(x)$ is identically 0

If the function is identically 0 then $\int_a^b f^2(x) dx$ will be 0; on the other hand if $\int_a^b f^2(x) dx$ is 0. So, $\int_a^b f^2(x) dx$ is equal to 0 then $f^2(x)$ is continuous $f^2(x)$ is bigger than or equal to 0 and which will imply that $f(x)$ has to be identically 0.

So, this is the first property. Second property is inner product of f with g it is same as inner product of g with f and that is because our multiplication of real numbers is commutative and third property which is known as linearity, f_1 plus f_2 its inner product with g will be inner product of f_1 with g plus inner product of f_2 with g and α times f comma g will be α times f comma g where α is a real number.

f_1 and f_2 these are continuous function.

So, these are the properties of inner product. So, we have defined the inner product and now we are going to look at the 3 functions

(Refer Slide Time: 34:44)

$f_0(x) = 1, f_1(x) = x, f_2(x) = x^2$.
 $g_0(x) = \frac{f_0(x)}{(\langle f_0, f_0 \rangle)^{1/2}}$.
Induced norm: $\|f\|_2 = \sqrt{\langle f, f \rangle}$.
 1) $\|f\|_2 \geq 0, \|f\|_2 = 0 \Leftrightarrow f(x) \equiv 0$.
 2) $\|\alpha f\|_2 = |\alpha| \|f\|_2, \alpha \in \mathbb{R}$.
 3) $\|f+g\|_2 \leq \|f\|_2 + \|g\|_2$: Triangle ineq.
 Cauchy-Schwarz inequality:
 $|\langle f, g \rangle| \leq \|f\|_2 \|g\|_2$

$f_0(x)$ is equal to 1, $f_1(x)$ is equal to x , $f_2(x)$ is equal to x^2 , look at $g_0(x)$ this will be equal to $\sqrt{\langle f_0, f_0 \rangle}$ we define it as $f_0(x)$ divided by inner product of f_0 with itself and raise to half we have got an induced norm; if you define norm of f to be square root of inner product of f with itself.

This is going to be bigger than or equal to 0. So, it is going to be greater than or equal to 0 we can take its positive square root and this is generally denoted by $\|f\|_2$.

So, this has properties that $\|f\|_2$ is bigger than or equal to 0 it is equal to 0 if and only if $f(x)$ is identically 0. Second, norm of αf will be equal to $|\alpha|$ times norm f where α belongs to \mathbb{R} and the third one is norm of $f + g$ is less than or equal to $\|f\|_2 + \|g\|_2$, this is known as triangle inequality and triangle inequality is proved using Cauchy Schwarz inequality, which is modulus of inner product of f with g that is less than or equal to $\|f\|_2 \|g\|_2$.

So, we have, look at the 3 functions $1, x, x^2$ from this we want to construct 3 other functions which I will denote by g_0, g_1, g_2 which will have property that if you look at the norm of each function, it is going to be equal to 1 and if you consider any 2 distinct functions like if you consider g_0 and g_1 its inner product will be 0, inner product of g_0 with g_2 will be 0 and inner product of g_1 with g_2 is equal to 0.

So this, the way we are going to do that is known as gram Schmidt orthonormalization process, we will do it for the 3 functions, but then one can define it for n functions.

So, now we will look at the function x^2 , we have got g_0 to be a constant polynomial g_1 to be a polynomial of degree 1 which is perpendicular to each other.

$f_2(x)$ is our function x^2 . So, from this function we will sort of subtract the component of our f_2 in the direction of g_0 and in the direction of g_1 .

So, we will construct our r_2 in such a manner that r_2 is perpendicular to both g_0 and g_1 our r_2 is going to be a quadratic polynomial which will be perpendicular to g_0 and g_1

(Refer Slide Time: 41:53)

Define $r_2(x) = f_2(x) - \langle f_2, g_0 \rangle g_0(x) - \langle f_2, g_1 \rangle g_1(x)$.

$$\langle r_2, g_0 \rangle = \langle f_2, g_0 \rangle - \langle f_2, g_0 \rangle \underbrace{\langle g_0, g_0 \rangle}_{=1} - \langle f_2, g_1 \rangle \underbrace{\langle g_1, g_0 \rangle}_{=0} = 0$$

$$\langle r_2, g_1 \rangle = \langle f_2, g_1 \rangle - \langle f_2, g_0 \rangle \underbrace{\langle g_0, g_1 \rangle}_{=0} - \langle f_2, g_1 \rangle \underbrace{\langle g_1, g_1 \rangle}_{=1} = 0$$

Define $g_2 = \frac{r_2}{\|r_2\|_2} \Rightarrow \|g_2\|_2 = 1$.

Define $r_2(x)$ to be equal to $f_2(x)$ minus inner product of f_2 with g_0 into $g_0(x)$ minus inner product of f_2 with g_1 into $g_1(x)$.

When you look at inner product of r_2 with g_0 that will be inner product of f_2 with g_0 minus inner product of f_2 with g_0 into inner product of g_0 with itself minus inner product of f_2 with g_1 and then inner product of g_1 with g_0 using the linearity of inner product.

This is 1, this is 0. So, this gets cancelled and then you get r_2 comma g_0 to be equal to 0; then you look at inner product of r_2 with g_1 that will be inner product of f_2 with g_1 minus inner product of f_2 with g_0 the coefficient and inner product of g_0 with g_1 minus inner product of f_2 with g_1 and inner product of g_1 with itself.

So, this is going to be equal to 1, this is equal to 0, these 2 will get cancelled and then you get r_2 comma g_1 is equal to 0. Next define g_2 to be equal to r_2 upon norm r_2 . So this will imply that norm of g_2 , 2 norm is going to be equal to 1.

So, this is the procedure for constructing g_0, g_1, g_2, g_3 orthonormal functions which we have obtained from the functions $1, x, x^2$ this was the general procedure.

Now, let us look at the interval to be minus 1 to 1 and find explicit expression for g_0, g_1, g_2 . So, when you look at the interval minus 1 to 1 our

(Refer Slide Time: 44:27)

The image shows a handwritten derivation on a whiteboard. It starts with $f_0(x) = 1, x \in [-1, 1]$. Then it calculates the norm $\|f_0\| = \left(\int_{-1}^1 dx\right)^{1/2} = \sqrt{2}$. Next, it defines $g_0(x) = \frac{1}{\sqrt{2}}$ and $r_1(x) = x - \langle f_1, g_0 \rangle g_0$. It then calculates the inner product $\langle f_1, g_0 \rangle = \int_{-1}^1 x \cdot \frac{1}{\sqrt{2}} dx = 0$. This leads to $r_1(x) = x$ and $g_1(x) = \frac{x}{\|r_1\|_2} = \sqrt{\frac{3}{2}} x$. Finally, it calculates the norm $\|r_1\|_2 = \left(\int_{-1}^1 x^2 dx\right)^{1/2} = \sqrt{\frac{2}{3}}$. An NPTEL logo is visible in the bottom left corner of the whiteboard image.

$f_0(x)$ is equal to $1, x$ belonging to minus 1 to 1 then norm f_0 will be integral minus 1 to 1 dx raise to half that is going to be equal to root 2 and hence our $g_0(x)$ is function 1 by root 2 it is f_0 upon norm f_0 ; next $r_1(x)$ is $f_1(x)$ which is x minus f_1 comma g_0 g_0 .

Let us calculate the inner product f_1 comma g_0 that is integral minus 1 to 1 $x g_0$ is 1 by root 2 dx . So, this is already equal to 0. So, we have got our $r_1(x)$ to be equal to x that will give us $g_1(x)$ to be equal to x divided by norm r_1 .

Now, what will be norm r_1 ? So, norm r_1 2 norm will be integral minus 1 to 1 $x^2 dx$ raise to half. So, this is going to be square root of $\frac{2}{3}$ and that will give us $g_1(x)$ to be root 3 by 2 x and now the third one

(Refer Slide Time: 46:25)

$$r_2(x) = x^2 - \langle f_2, g_0 \rangle g_0 - \langle f_2, g_1 \rangle g_1$$
$$f_2(x) = x^2, \quad g_0(x) = \frac{1}{\sqrt{2}}, \quad g_1(x) = \sqrt{\frac{3}{2}} x$$
$$\langle f_2, g_0 \rangle = \int_{-1}^1 \frac{x^2}{\sqrt{2}} dx = \frac{2}{3\sqrt{2}} = \frac{\sqrt{2}}{3}$$
$$\langle f_2, g_1 \rangle =$$

So, let us look at $r_2(x)$. So, $r_2(x)$ is going to be equal to x^2 minus inner product of f_2 with g_0 into g_0 minus inner product of f_2 with g_1 g_1 where our $f_2(x)$ is x^2 , g_0 is $1/\sqrt{2}$ and $g_1(x)$ is equal to $\sqrt{3/2} x$. So, inner product of f_2 with g_0 this will be integral minus 1 to 1 x^2 by $\sqrt{2} dx$.

So, this is going to be equal to $2/3\sqrt{2}$ **2 by 3**. So, this is going to be $\sqrt{2}/3$ when we look at inner product of f_2 with g_1 this is going to be equal to integral minus 1.
