Boundary Value Problems

We are considering stability of various methods. So, single step methods such as euler's method or runge kutta method will not have any problem about stability ,because when we consider an approximate method initial value problem is a differential equation of order one.

So, that differential equation you replace by difference equation. So, in case of single step methods you replace differential equation of first order by difference equation of the first order.

Whereas for multi step method such as say midpoint method, your differential equation of order 1 is replaced by difference equation of order two. So, then the difference equation will have two solutions and this creates some problem. So, we are going we are studying those things

So, as a representative case we are looking at the initial value problem, $y' = \lambda y$ with $y(0) = 1$. So, we know its exact solution the exact solution is going to be $e^{\lambda x}$ for this particular differential equation we want to see what happens when you apply say euler's method runge kutta method or midpoint method.

(Refer Slide Time: 02:15)

Stability

$$y' = \lambda y, \quad y(0) = 1$$
$$\text{Exact Solution: } y(x) = e^{\lambda x}, \quad x \in [0, b]$$
$$h = \frac{b}{N}, \quad x_n = n h$$
$$\text{Euler's Method: } y_{n+1} = y_n + h \lambda y_n$$
$$= (1 + h \lambda) y_n$$
$$= (1 + h \lambda)^{n+1}$$

So, y' is equal to λy , $y(0) = 1$. Let us look at solution over interval 0 to b the interval 0 to b will be subdivided into N equal parts. So, h is going to be equal to b by n .

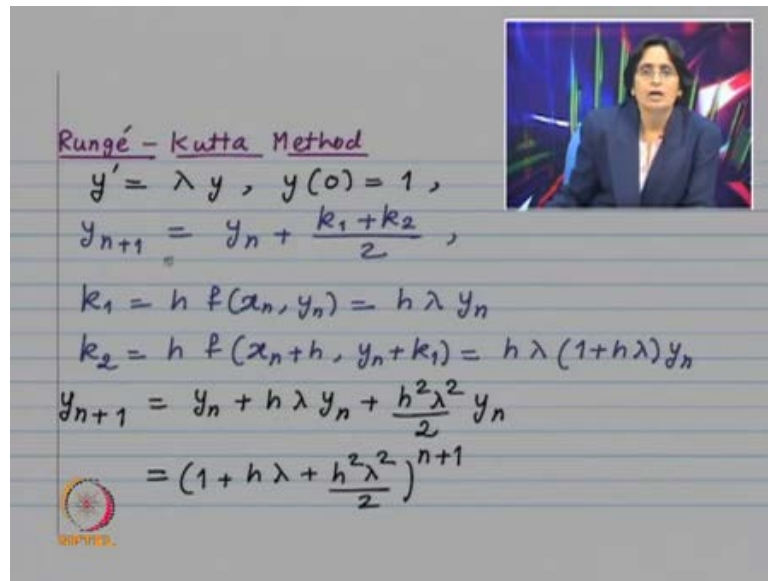

x_n point is going to be equal to $n h$ because our x_0 is equal to 0 in the Euler's method we have got y_{n+1} is equal to $y_n + h$ times f of x_n, y_n our $f(x, y)$ is λy .

So, that is why you have $y_n + h \lambda y_n$. So, that means, it is equal to $1 + h \lambda y_n$ now replacing y_n by $1 + h \lambda y_{n-1}$ and so, on you get y_{n+1} is equal to $1 + h \lambda$ raise to $n + 1$.

So, this is what I was talking that y' is equal to λy it is a differential equation of first order here you have got y_{n+1} is equal to $1 + h \lambda y_n$. So, again it is a difference equation of first order.

Now, look at the Runge-Kutta method

(Refer Slide Time: 03:36)

Runge - Kutta Method

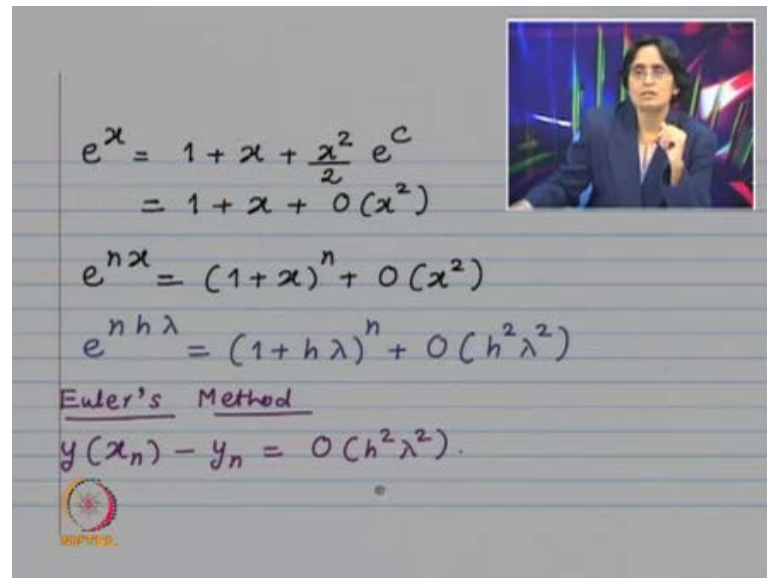

$$y' = \lambda y, y(0) = 1,$$
$$y_{n+1} = y_n + \frac{k_1 + k_2}{2},$$
$$k_1 = h f(x_n, y_n) = h \lambda y_n$$
$$k_2 = h f(x_n + h, y_n + k_1) = h \lambda (1 + h \lambda) y_n$$
$$y_{n+1} = y_n + h \lambda y_n + \frac{h^2 \lambda^2}{2} y_n$$
$$= \left(1 + h \lambda + \frac{h^2 \lambda^2}{2}\right)^{n+1}$$

in the runge kutta method y_{n+1} is given by $y_n + \frac{k_1 + k_2}{2}$ where k_1 is nothing, but h times f of x_n, y_n k_2 is h times f of $x_n + h, y_n + k_1$ function $f(x, y)$ is λy . So, that is why k_1 becomes h times λy_n .

And k_2 will be h then λ times $y_n + k_1$, but $y_n + k_1$ is $h \lambda y_n$. So, that is why k_2 becomes $h \lambda (1 + h \lambda) y_n$ substitute in this formula. So, we have got y_{n+1} is equal to $y_n + h \lambda y_n + \frac{h^2 \lambda^2}{2} y_n$.

So, again it is a difference equation of first order y_{n+1} is going to be equal to $1 + h \lambda + \frac{h^2 \lambda^2}{2}$ into y_n and the solution will be given by this.

(Refer Slide Time: 04:56)

$$e^x = 1 + x + \frac{x^2}{2} e^c$$
$$= 1 + x + O(x^2)$$
$$e^{nx} = (1+x)^n + O(x^2)$$
$$e^{nh\lambda} = (1+h\lambda)^n + O(h^2\lambda^2)$$
Euler's Method
$$y(x_n) - y_n = O(h^2\lambda^2).$$

Now let us look at the difference or let us look at the error. So, in order to find an error we look at the expansion of e^x . So, e^x function is equal to $1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \dots$. Hence I can say that e^x is equal to $1 + x + \text{terms of higher order}$; that means, terms of the order of x^2 . If I write three terms then e^x will be $1 + x + \frac{x^2}{2} + \text{terms of the order of } x^3$.

So, when we want to compare the exact solution with the approximation which we have obtained by using Euler's method we are going to retain 2 terms. e^x is equal to $1 + x$. When we want to compare the error in the Runge-Kutta method, we will keep three terms.

So, we have e^x is equal to $1 + x + \text{higher order terms}$. So, that gives you e^{nx} will be equal to $1 + nx + \text{terms of the order of } x^2$. So, this is what one uses and gets $e^{nh\lambda}$ is $1 + nh\lambda + \text{term of the order of } x^2$.

(Refer Time Slide: 04:56)

The image shows handwritten mathematical derivations on lined paper. The first line is $e^x = 1 + x + \frac{x^2}{2} e^c$. The second line is $= 1 + x + O(x^2)$. The third line is $e^{nx} = (1+x)^n + O(x^2)$. The fourth line is $e^{nh\lambda} = (1+h\lambda)^n + O(h^2\lambda^2)$. Below these is the text "Euler's Method" and the equation $y(x_n) - y_n = O(h^2\lambda^2)$. There is a small logo in the bottom left corner of the paper.

E raise to put x is equal to $n h a$ or put x is equal to $h \lambda$. So, you are going to have e raise to $n h \lambda$ is equal to $1 + h \lambda$ raise to n plus term of the order of h square λ square this $1 + h \lambda$ raise to n that is the approximation in the Eulers method.

So, that is our y_n our x_n is $n h$. So, e raise to $n h \lambda$ because thus exact solution is e raise to λh this is nothing, but y at x_n . So, we have y at x_n minus y_n is equal to term of the order of x square λ square.

So, this is consistent with what we have been saying that the local discretization error in euler's method is going to be h square in runge kutta method of order two ,the local discretization error will be of the order of h cube.

So, now let us look at the error in the runge kutta method.

(Refer Slide Time: 08:05)

$$e^x = 1 + x + \frac{x^2}{2} + O(x^3)$$
$$e^{nx} = \left(1 + x + \frac{x^2}{2}\right)^n + O(x^3)$$
$$e^{nh\lambda} = \left(1 + h\lambda + \frac{h^2\lambda^2}{2}\right)^n + O(h^3\lambda^3)$$

Runge - Kutta Method

$$y(x_n) - y_n = O(h^3\lambda^3)$$

So, in case of runge kutta method you have got y_n to be $1 + h\lambda + \frac{h^2\lambda^2}{2}$ whole thing raise to n that is what we obtained

(Refer Slide Time: 08:21)

Runge - Kutta Method

$$y' = \lambda y, \quad y(0) = 1,$$
$$y_{n+1} = y_n + \frac{k_1 + k_2}{2},$$
$$k_1 = h f(x_n, y_n) = h\lambda y_n$$
$$k_2 = h f(x_n + h, y_n + k_1) = h\lambda(1 + h\lambda)y_n$$
$$y_{n+1} = y_n + h\lambda y_n + \frac{h^2\lambda^2}{2} y_n$$
$$= \left(1 + h\lambda + \frac{h^2\lambda^2}{2}\right)^{n+1}$$

y_{n+1} is equal to $1 + h\lambda + \frac{h^2\lambda^2}{2}$ raise to $n+1$. So, if I consider y_n then it is going to be n th power of this bracket. So, thus this is going to be your

(Refer Slide Time: 04:56).

$$e^x = 1 + x + \frac{x^2}{2} e^c$$
$$= 1 + x + O(x^2)$$
$$e^{nx} = (1+x)^n + O(x^2)$$
$$e^{nh\lambda} = (1+h\lambda)^n + O(h^2\lambda^2)$$

Euler's Method

$$y(x_n) - y_n = O(h^2\lambda^2).$$

$y_n e^{nh\lambda}$ as before it is going to be y at x_n . So, $y(x_n) - y_n$ is of the order of $h^3 \lambda^3$.

So, truncation error to be of the order of h^3 as one expects. So, these are the single step methods

(Refer Slide Time: 09:04)

Midpoint Method

$$y' = \lambda y, \quad y(0) = 1$$
$$y_{n+1} = y_{n-1} + 2h f(x_n, y_n)$$
$$= y_{n-1} + 2h\lambda y_n$$

Difference Equation:

$$y_{n+1} - 2h\lambda y_n - y_{n-1} = 0$$
$$y_0 = 1, \quad y_1 = y(h) = e^{\lambda h}$$

And now let us look at the midpoint method we are looking at this initial value problem the midpoint method is $y_{n+1} = y_{n-1} + 2h f(x_n, y_n)$.

Very much similar to the Euler's method where instead of y_n we have got y_{n-1} and instead of $h f(x_n, y_n)$, we are saying $2 h f(x_n, y_n)$, and last time we saw that the local discretization error is h^3 . So, in the case of Euler's method it is h^2 for midpoint method it is h^3 . But as we will see that there are some problems with this method.

Now, look at this formula. So, you have got y_{n+1} is equal to $y_{n-1} + 2 h \lambda y_n$ if I take it on the other side you have got $y_{n+1} - 2 h \lambda y_n - y_{n-1}$ is equal to 0.

So, this is a difference equation and in the difference equation y_{n+1} is in terms of y_n and y_{n-1} . So, this is differential equation of first order this is difference equation of the second order in order to determine the solution of this uniquely you will need two conditions like in the case of differential equation.

If you have got differential equation of first order then the unique solution is determined by one condition. If you have got differential equation of second order, then you need 2 conditions. These two conditions they can be initial conditions or they can be boundary conditions. So, now, we have got a difference equation of second order. So, we will need two conditions 1 condition is going to be y_0 is equal to 1.

The same as in the case of initial value problem now, here we need to supply 1 more condition now since in this initial value problem. We know the exact solution the exact solution is $e^{\lambda h}$.

What is y_1 y_1 is approximation to y at x_1 our interval is 0 to b we are subdividing it into n equal parts. So, our x_0 is 0 x_1 is going to be equal to h . So, then y_1 which is approximation to y at x_1 that is going to be we are we will supplied to be $e^{\lambda h}$.

So, now let us find solution of this difference equation with two conditions y_0 to be equal to 1 and y_1 to be equal to $e^{\lambda h}$.

(Refer Slide Time: 12:28)

$$y_{n+1} - 2h\lambda y_n - y_{n-1} = 0, n=1,2,\dots$$

$$y_n = r^n$$

$$r^{n+1} - 2h\lambda r^n - r^{n-1} = 0 \Rightarrow$$

$$r^2 - 2h\lambda r - 1 = 0$$

$$r_1 = \frac{2h\lambda + \sqrt{4h^2\lambda^2 + 4}}{2} = h\lambda + \sqrt{1+h^2\lambda^2}$$

$$r_2 = h\lambda - \sqrt{1+h^2\lambda^2}$$

$$y_n = \beta_1 r_1^n + \beta_2 r_2^n, y_0 = 1, y_1 = e^{h\lambda}$$

Now, the solution of the difference equation is assumed to be of the form r^n , where r is to be determined. Then $y_{n+1} = r^{n+1}$, $y_n = r^n$, and $y_{n-1} = r^{n-1}$. Substituting these into the equation gives $r^{n+1} - 2h\lambda r^n - r^{n-1} = 0$, which simplifies to $r^2 - 2h\lambda r - 1 = 0$.

This implies that $r^2 - 2h\lambda r - 1 = 0$ is a quadratic equation. Solving for r , we get $r_1 = h\lambda + \sqrt{1+h^2\lambda^2}$ and $r_2 = h\lambda - \sqrt{1+h^2\lambda^2}$. The general solution is $y_n = \beta_1 r_1^n + \beta_2 r_2^n$.

So, the roots of this quadratic equation are $r_1 = h\lambda + \sqrt{1+h^2\lambda^2}$ and $r_2 = h\lambda - \sqrt{1+h^2\lambda^2}$. The general solution is $y_n = \beta_1 r_1^n + \beta_2 r_2^n$.

The second root will be given by $r_2 = h\lambda - \sqrt{1+h^2\lambda^2}$. The general solution y_n is given by $y_n = \beta_1 r_1^n + \beta_2 r_2^n$. The constants β_1 and β_2 will be determined by the conditions $y_0 = 1$ and $y_1 = e^{h\lambda}$.

So, in the case of the midpoint method, the solution is given by $y_n = \beta_1 r_1^n + \beta_2 r_2^n$, where β_1 and β_2 are constants determined by the initial conditions.

Our y_n is approximation to y at x_n y is the exact solution the solution of our difference equation is given by $\beta_1 r_1^n + \beta_2 r_2^n$ the first part corresponds to the exact solution other part is extraneous solution.

It appears because you're replacing differential equation of first order by difference equation of the second order. So, this extraneous solution this is this is what causes the problem like depending on the value of λ it can dominate the exact solution.

Now, how this happens let us look at it in more detail.

(Refer Slide Time: 15:42)

$$y_n = \beta_1 r_1^n + \beta_2 r_2^n$$

$$y_0 = 1, \quad y_1 = e^{h\lambda}$$

$$r_1 = h\lambda + \sqrt{1 + h^2\lambda^2}, \quad r_2 = h\lambda - \sqrt{1 + h^2\lambda^2}$$

$$\beta_1 + \beta_2 = 1, \quad \beta_1 r_1 + \beta_2 r_2 = y_1$$

$$\beta_2 = 1 - \beta_1, \quad \beta_1(r_1 - r_2) + r_2 = y_1$$

$$\beta_1 = \frac{y_1 - r_2}{2\sqrt{1 + h^2\lambda^2}} \rightarrow 1 \text{ as } h \rightarrow 0$$

$$\beta_2 \rightarrow 0$$

So, we have y_n is equal to $\beta_1 r_1^n + \beta_2 r_2^n$ y_0 is equal to 1 y_1 is equal to $e^{h\lambda}$.

We have seen that r_1 the first root is given by $h\lambda + \sqrt{1 + h^2\lambda^2}$ and this is the second root y_0 is equal to 1 put n is equal to 0. So, this will become $\beta_1 + \beta_2 = 1$.

Then put n is equal to 1. So, y_1 ; that means, $\beta_1 r_1 + \beta_2 r_2$ will be equal to y_1 . So, the constants β_1 and β_2 , they are determined by these 2 conditions. So, the first condition tells us that β_2 is going to be equal to $1 - \beta_1$.

The second equation tells us when I substitute for beta 2 I will get beta 1 into $r_1 - r_2$ plus r_2 is equal to y_1 , that gives us beta 1 is equal to $y_1 - r_2$ on the other side $y_1 - r_2$ and divide by $r_1 - r_2$.

But look at here r_1 is $h\lambda + \sqrt{1 + h^2\lambda^2}$ r_2 is $h\lambda - \sqrt{1 + h^2\lambda^2}$. So, when I consider $r_1 - r_2$ $h\lambda$ will get cancelled and you're left with $2\sqrt{1 + h^2\lambda^2}$.

Now, as h tends to 0. So, when h tends to 0 what is going to happen is y_1 is $e^{h\lambda}$. So, when h tends to 0 $e^{h\lambda}$ will tend to 1 then r_2 this part will tend to 0 this part will tend to minus 1.

And hence when I consider $y_1 - r_2$ that is going to converge to $e^{h\lambda} - r_2$, in the denominator you have got term $2\sqrt{1 + h^2\lambda^2}$. So, that will tend to 2.

So, which is why beta 1 will tend to 1 as h tends to 0 and beta 2 will tend to 0.

So, our y_n which consists of 2 parts the part beta 1 r_1^n that corresponds to our exact solution and this is something extra.

(Refer Slide Time: 18:50)

The image shows a slide with handwritten mathematical work. At the bottom left, there is a small circular logo with the text 'WPT12' below it.

$$y' = \lambda y, \quad y(0) = 1$$

$$y_n = \beta_1 r_1^n + \beta_2 r_2^n,$$

$$r_1 = h\lambda + \sqrt{1 + h^2\lambda^2}, \quad r_2 = h\lambda - \sqrt{1 + h^2\lambda^2}$$

$$f(x) = \sqrt{1+x}, \quad f'(x) = \frac{1}{2\sqrt{1+x}}$$

$$f(x) = 1 + x f'(c) = 1 + O(x)$$

Now, let us look at this in more carefully. What is our r_1 is $h\lambda$ plus square root of $1 + h^2\lambda^2$, as we did in case of e^{hx} we can do for $f(x)$ is equal to root of $1 + x$ its derivative is given by $\frac{1}{2\sqrt{1+x}}$.

So, $f(x)$ is equal to $f(0) + x f'(0)$. So, what I am interested is saying that square root of $1 + x$ is $1 + \frac{1}{2}x + O(x^2)$, then our r_1 will be $h\lambda$ plus square root of $1 + h^2\lambda^2$. So, this I can say that this is equal to $1 + \frac{1}{2}h^2\lambda^2 + O(h^4\lambda^4)$.

(Refer Slide Time: 19:53)

The image shows handwritten mathematical derivations on a lined background. The equations are as follows:

$$r_1 = h\lambda + \sqrt{1 + h^2\lambda^2}$$

$$= h\lambda + 1 + O(h^2\lambda^2)$$

$$r_2 = h\lambda - \sqrt{1 + h^2\lambda^2}$$

$$= h\lambda - 1 + O(h^2\lambda^2)$$

$$r_1^n = (1 + h\lambda)^n + O(h^2\lambda^2)$$

$$r_2^n = (-1)^n (1 - h\lambda)^n + O(h^2\lambda^2)$$

At the bottom left of the image, there is a small circular logo with the word 'WU' inside it.

So, r_1 is equal to $h\lambda$ plus square root of $1 + h^2\lambda^2$. So, that is $h\lambda + 1 + \text{higher order terms}$ for r_2 , the second root we have $h\lambda$ minus square root of $1 + h^2\lambda^2$.

So, using similar argument you will get this to be equal to $h\lambda - 1 + \text{higher order terms}$. Now r_1 raise to n that is $(1 + h\lambda)^n + \text{higher order terms}$ r_2 raise to n will be $(-1)^n (1 - h\lambda)^n + \text{higher order terms}$.

So, now our solution is $\beta_1 r_1^n + \beta_2 r_2^n$. So, let us substitute in that we are trying to look at what our y_n looks like.

When we considered euler's method or runge kutta method things where is here, we got a formula for y_{n+1} in terms of y_n , then the same formula tells us the relation between y_n and y_{n-1} .

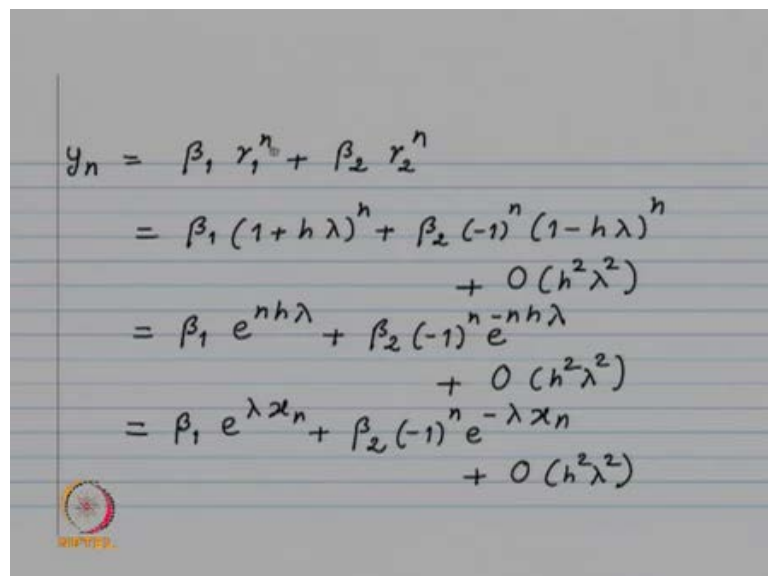

So, like that we could go up to y_0 y_0 is equal to 1 that is given to us. So, that is how in case of euler's method, we got y_n to be equal to $1 + h\lambda$ raised to n .

Similar was the case with runge kutta method what the midpoint method we have to solve a quadratic equation get its roots, and then our solution is y_n is equal to $\beta_1 r_1^n + \beta_2 r_2^n$. Now this r_1^n and r_2^n .

We have shown that r_1^n will be $1 + h\lambda$ raised to n plus higher order terms our exact solution is $e^{\lambda x}$. So, when I consider y at x_n y is the exact solution x_n is going to be n times h . So, y at x_n is $e^{\lambda n h}$. So, as we compared in case of euler's method or runge kutta method y at x_n minus y_n , we want to do similar thing here. So, that is why r_1^n we write as $1 + h\lambda$ raised to n .

So, then I can compare $e^{\lambda n h}$ and $1 + h\lambda$ raised to n . So, that is the idea. So, we have

(Refer Slide Time: 23:10)

$$\begin{aligned}
 y_n &= \beta_1 r_1^n + \beta_2 r_2^n \\
 &= \beta_1 (1+h\lambda)^n + \beta_2 (-1)^n (1-h\lambda)^n \\
 &\quad + O(h^2\lambda^2) \\
 &= \beta_1 e^{nh\lambda} + \beta_2 (-1)^n e^{-nh\lambda} \\
 &\quad + O(h^2\lambda^2) \\
 &= \beta_1 e^{\lambda x_n} + \beta_2 (-1)^n e^{-\lambda x_n} \\
 &\quad + O(h^2\lambda^2)
 \end{aligned}$$

y_n to be $\beta_1 r_1^n + \beta_2 r_2^n$ r_1^n is $1 + h\lambda$ raised to n plus terms of the order of $h^2\lambda^2$ for r_2^n we have got $(-1)^n$ and $1 - h\lambda$ raised to n .

This $1 + h\lambda$ raised to n will be equal to $e^{\lambda x_n}$, plus terms of the order of $h^2\lambda^2$. Similarly here you will get $e^{-\lambda x_n}$ and thus our y_n is equal to $\beta_1 e^{\lambda x_n}$.

Plus $\beta_2 (-1)^n e^{-\lambda x_n}$ plus terms of the higher order. So, we have

(Refer Slide Time: 24:08)

The slide contains the following handwritten text:

$$y' = \lambda y, \quad y(0) = 1$$

$$y(x) = e^{\lambda x}$$

$$y_n = \beta_1 e^{\lambda x_n} + \beta_2 (-1)^n e^{-\lambda x_n} + O(h^2\lambda^2)$$

$$\beta_1 \rightarrow 1, \quad \beta_2 \rightarrow 0 \quad \text{as } h \rightarrow 0.$$

This is our initial value problem, this is the exact solution. $y(x)$ is equal to $e^{\lambda x}$. y_n is approximation to y at x_n . So, y at x_n is going to be equal to $e^{\lambda x_n}$.

So, this presence of this term is normal. y_n is approximation. $e^{\lambda x_n}$ is the exact solution. You have got this error $h^2\lambda^2$, but this term $\beta_2 (-1)^n e^{-\lambda x_n}$. Now if I am doing exact calculations then the initial value from our initial values they take care like you have got two terms, but the coefficient of the term which is extra which should not be there.

Its coefficient tends to 0 as h tends to zero. So, when h is small enough, the second term should not matter, because we have got $\beta_1 e^{\lambda x_n}$ plus $\beta_2 e^{-\lambda x_n}$.

Plus term which is of the order of $h^2 \lambda^2$, we have shown that β_1 will tend to 1 as h tends to 0 the term order of $x^2 \lambda^2$ as h tends to 0 that term also will tend to 0.

The second term is $\beta_2 e^{-\lambda x_n}$ of which the coefficient β_2 is tending to 0. So, the exact computations will not cause any problem, but we do the computations in finite precision. So, that is why there are going to be round off error and when you look at the term $\beta_2 e^{-\lambda x_n}$.

Suppose your λ is less than 0 we are looking at y' is equal to λy . So, if λ is less than 0 $e^{-\lambda x_n}$ that becomes significant. So, we have

(Refer Slide Time: 26:54)

$$y_n = \beta_1 e^{\lambda x_n} + \beta_2 (-1)^n e^{-\lambda x_n} + O(h^2 \lambda^2)$$

• extraneous solution

$\lambda > 0$: OK!

$\lambda < 0$: extraneous solution dominates the true solution.

Error increases exponentially.

y_n is equal to $\beta_1 e^{\lambda x_n}$ plus $\beta_2 (-1)^n e^{-\lambda x_n}$ which is extraneous solution.

And the terms of the higher order, if λ is less than 0 $e^{-\lambda x_n}$ will increase you are going away from 0, you are looking at the interval 0 to b . So, this term will increase exponentially our β_2 , because of the round off error it will not tend to 0. So, this term will start dominating this term our approximate solution consist of 2 parts. So, this is the part which corresponds to the exact solution, but if λ is less than 0 then this solution becomes dominant which is corresponding to the error.

And you will get the error to be increasing Last time we looked at specific example. It was $y' = -2y + 1$ and there I have shown you the numerical results where the euler's method ,if you applied to that particular example the error goes on decreasing whereas, in the case of midpoint method the error instead of decreasing, it went on increasing ,we had looked at the interval to be 0 to four.

So, this is the problem with the midpoint method to the same problem whether λ is less than 0 or λ greater than 0 ,euler's method runge kutta method there will not be any such problem .

So, that is why if your λ is bigger than 0, then you should use midpoint method because then in that case even though you have a extraneous solution , $\beta_2 e^{\lambda x_n}$,whether it tends to 0 or not $e^{\lambda x_n}$ with λ bigger than 0 that will become smaller and smaller.

And then it would not have it would not affect our true solution, now I want to consider or I want to rather state results for the adams bashforth method and then we will go to boundary value problem.

So, in case of adams bashforth method again it is a multi step formula. So, let us look at the formula.

(Refer Time Slide: 29:58)

Adams - Bashforth Method

$$y_{n+1} = y_n + \frac{h}{24} [55g_n - 59g_{n-1} + 37g_{n-2} - 9g_{n-3}]$$

$$g_n = g(x_n) = f(x_n, y_n)$$

$$y_n = \beta_1 r_1^n + \beta_2 r_2^n + \beta_3 r_3^n + \beta_4 r_4^n$$

true solution

$$|r_2| < 1, |r_3| < 1, |r_4| < 1, h \text{ small enough}$$

$$y' = \lambda y, y(0) = 1 : \text{Stable}$$

So, we have y_{n+1} is equal to y_n , plus h by $2.455g_n - 59g_n$, minus 1 plus $37g_n - 2$, minus $9g_n - 3$, where g_n is value of g at x_n .

G is our function $f(x, y)$. So, it is $f(x_n, y_n)$. So, here we have got a formula for y_{n+1} in terms of y_n then y_{n-1} , y_{n-2} , y_{n-3} . So, this is going to be or if we if you consider y' is equal to λy you will get a difference equation of order 4.

In case of midpoint method we had difference equation of order 2. So, we got a solution of that $i\beta_1 r_1$ raise to n plus β_2 raise to n , in this case it is going to be difference equation of order 4.

So, that is why our solution will be of this type $\beta_1 r_1$ raise to n plus $\beta_2 r_2$ raise to n plus $\beta_3 r_3$ raise to n plus $\beta_4 r_4$, raise to n of which 1 corresponds to the true solution.

All the three remaining terms, they are extraneous they should not be there, but in this case what happens is what 1 can show is modulus of r_2 modulus of r_3 and modulus of r_4 , they are less than 1 for h small enough and then because they are less than 1 their effect will go on diminishing, when you increase n and it they would not affect our true solution.

So, the Adams-Bashforth method that is going to be stable for this y' is equal to λy y at 0 is equal to one. So now, this completes our study of initial value problem now we want to consider a boundary value problem.

So, as the name suggest the boundary value problem will be the conditions, will be given at the 2 end points of the intervals or at the boundary. So, we are going to look at second order differential equation with 2 boundary conditions given now what I am going to do is just describe what is the finite difference method. So, it is a classical method. So, we will describe the finite difference method and then that will complete our solution of approximate solution of differential equation there are other methods for solving the boundary value problems.

Which we will not be considering. So, we have got

(Refer Slide Time: 33:20)

Boundary Value Problem

$$y''(x) + f(x)y'(x) + g(x)y(x) = r(x),$$
$$x \in [a, b]$$
$$y(a) = \alpha, \quad y(b) = \beta$$
$$y' = \frac{dy}{dx}, \quad y'' = \frac{d^2y}{dx^2}$$

f, g, r : continuous.

this is our boundary value problem $y''(x) + f(x)y'(x) + g(x)y(x) = r(x)$ for x belonging to interval a to b .

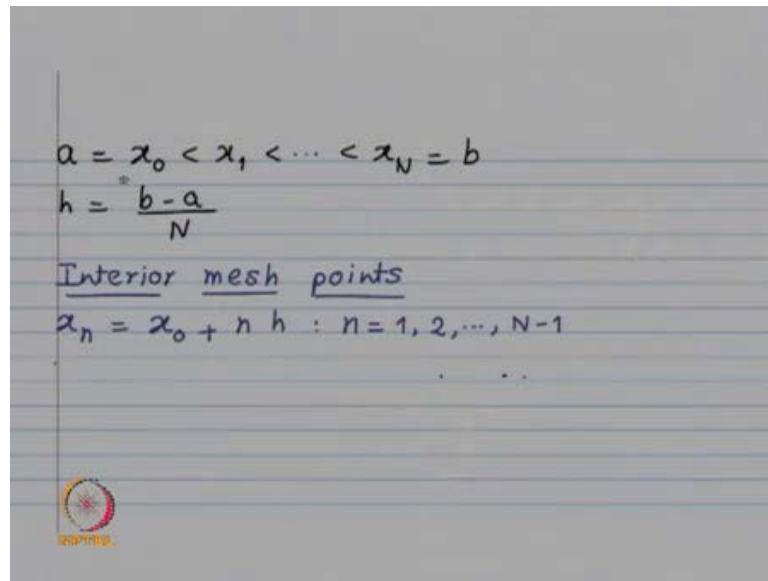

You need to have two conditions. So, the conditions are $y(a) = \alpha$ and $y(b) = \beta$. y' is $\frac{dy}{dx}$, y'' is second derivative, $\frac{d^2y}{dx^2}$. Our assumption is the coefficient functions f and g and the right hand side r , these are going to be continuous functions on interval a to b .

So, this is second order boundary value problem, we can have fourth order boundary value problem, which can have the fourth derivative or the derivatives up to order four appearing and then the boundary conditions they will involve not only the function values, but may be also the derivative values or their combination.

So, now here is our boundary value problem where the derivatives they appear once again our aim will be to find approximation to the exact solution y at finite number of points.

As we have done before we will divide our interval a to b into n equal parts and our aim is to find approximation at these $n + 1$ discrete points. So, we have this is a uniform partition

(Refer Slide Time: 35:13)

$$a = x_0 < x_1 < \dots < x_N = b$$
$$h = \frac{b-a}{N}$$

Interior mesh points

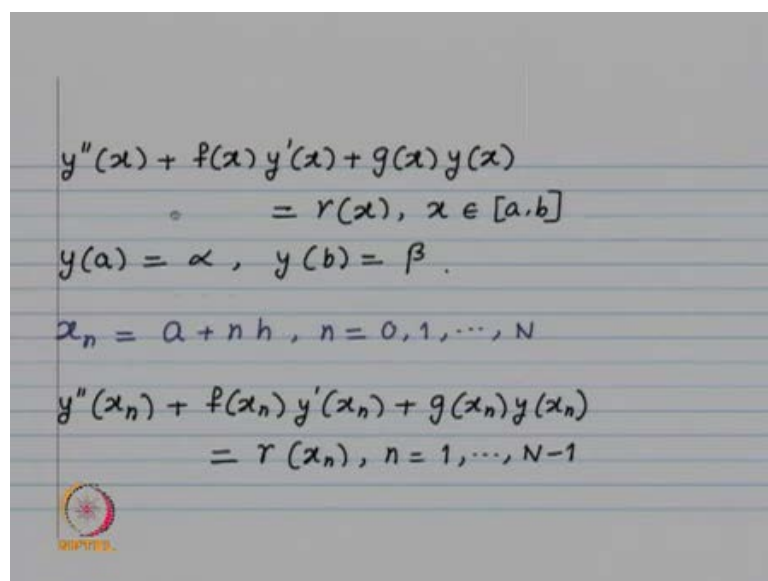

$$x_n = x_0 + n h : n = 1, 2, \dots, N-1$$

of interval a b h is the length of sub interval b minus a by n and interior mesh points , they are given by x_n is equal to x_0 plus $n h$.

N is equal to 1 to up to n minus 1 when n is equal to 0 it is x_0 is equal to a the end point when n is equal to capital N then it is going to be the right end point b

The value of our function y is given at a and at b . So, those values they are known. So, our aim will be to find approximation to y at x_n at these interior mesh points

(Refer Slide Time: 36:04)

$$y''(x) + f(x)y'(x) + g(x)y(x) = r(x), x \in [a, b]$$
$$y(a) = \alpha, y(b) = \beta$$
$$x_n = a + n h, n = 0, 1, \dots, N$$
$$y''(x_n) + f(x_n)y'(x_n) + g(x_n)y(x_n) = r(x_n), n = 1, \dots, N-1$$

Now this is satisfied for every x belonging to a, b . So, in particular it will be satisfied at x_n . So, we have got $y''(x_n) + f'(x_n) y'(x_n) + g(x_n) y(x_n) = r(x_n)$.

N is equal to 1 to up to $n-1$, I do not write for the end points because we already know what is y at x_0 and y at x_n . So, now, the idea in the finite difference method is this $y'(x_n)$ and $y''(x_n)$ these are the derivative values. So, you replace these derivative values by finite difference we have considered numerical differentiation.

So, if you have got a function f its derivative at a . So, we looked at the forward difference formula that is $f'(a)$ is approximately equal to $\frac{f(a+h) - f(a)}{h}$ or more symmetric formula, will be $f'(a)$ to be approximately equal to $\frac{f(a+h) - f(a-h)}{2h}$.

So, you choose a point $a+h$ and $a-h$ and then look at the values there take the difference and divided by $2h$. Now the advantage is in that case, the error was of the order of h^2 , where as you get error to be of the better order if you consider central difference formula. Same thing is true for the second derivative $f''(a)$, will be approximately equal to $\frac{f(a+h) - 2f(a) + f(a-h)}{h^2}$. So, what we are going to do is this $y'(x_n)$ and $y''(x_n)$.

We will replace the values by central difference formula and that is going to give us a tri-diagonal system. So, our unknown is going to be y_n which is approximation to y at x_n . So, here is our equation.

(Refer Slide Time: 38:45)

The image shows a handwritten derivation on lined paper. At the top, the differential equation is written as $y''(x_n) + p(x_n)y'(x_n) + q(x_n)y(x_n) = r(x_n), n = 1, \dots, N-1$. Below this, the function value is approximated as $y(x_n) \approx y_n$. The first derivative is approximated using the central difference formula: $y'(x_n) \approx \frac{y_{n+1} - y_{n-1}}{2h}$. Finally, the second derivative is approximated as $y''(x_n) \approx \frac{y_{n+1} - 2y_n + y_{n-1}}{h^2}$. A small circular logo with the word 'NPTEL' is visible in the bottom left corner of the paper.

So, this equation is exact there is no approximation. So, $y(x_n)$ it is approximate value we denote by y_n this is the central difference formula. So, we have got

(Refer Slide Time: 39:06)

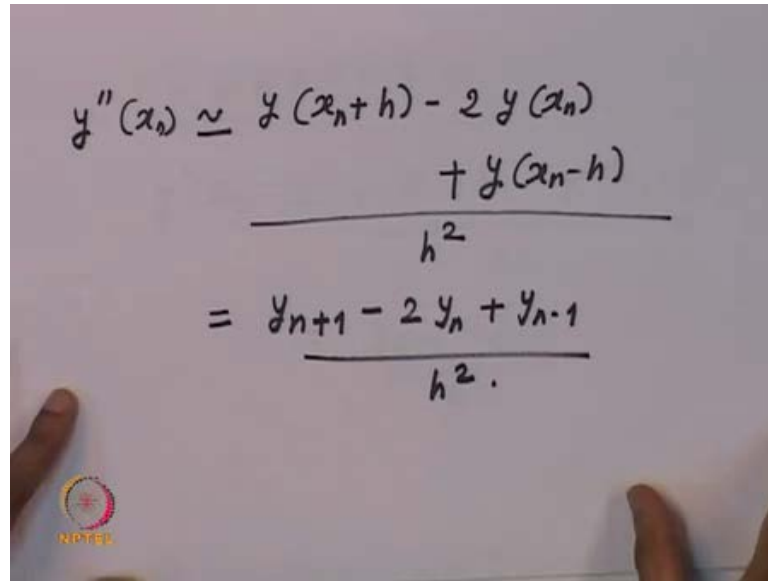

The image shows a handwritten derivation on white paper. At the top, the characteristic equation is written as $r^2 - 2h\lambda r - 1 = 0$. Below this, the first derivative is approximated as $y'(x_n) \approx \frac{y(x_n+h) - y(x_n-h)}{2h}$. This is then simplified to $= \frac{y_{n+1} - y_{n-1}}{2h}$. A hand holding a pen is visible in the bottom right corner. A small circular logo with the word 'NPTEL' is visible in the bottom left corner of the paper.

$y'(x_n)$ to be approximately equal to $y(x_n+h) - y(x_n-h)$ divided by $2h$.

So, this will be nothing, but $y_{n+1} - y_{n-1}$ divided by $2h$.

So, this is for the first derivative

(Refer Slide Time: 39:39)

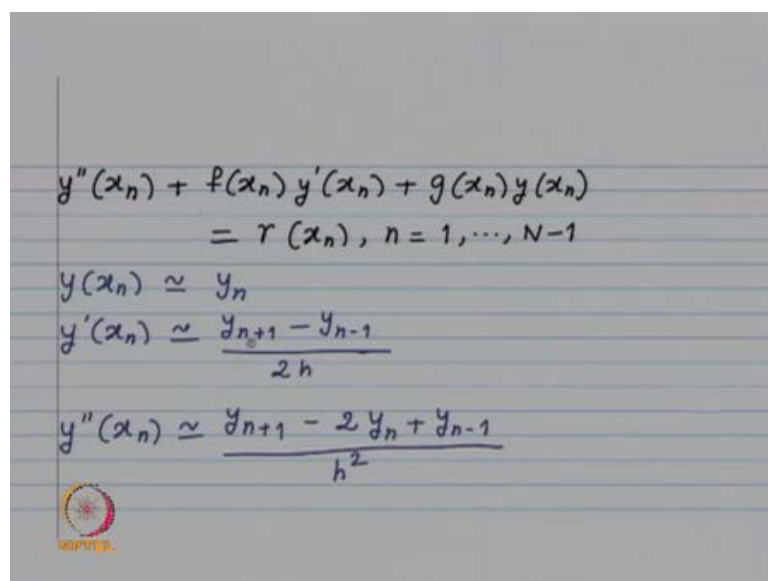

A photograph of a whiteboard with handwritten mathematical formulas. The top formula is $y''(x_n) \approx \frac{y(x_{n+h}) - 2y(x_n) + y(x_{n-h}))}{h^2}$. Below it is the simplified version $= \frac{y_{n+1} - 2y_n + y_{n-1}}{h^2}$. A small NPTL logo is visible in the bottom left corner.

$$y''(x_n) \approx \frac{y(x_{n+h}) - 2y(x_n) + y(x_{n-h}))}{h^2}$$
$$= \frac{y_{n+1} - 2y_n + y_{n-1}}{h^2}$$

for the second derivative $y''(x_n)$ will be approximately equal to y at $x_n + h$ minus 2 times y at x_n plus y at $x_n - h$ whole thing divided by h^2 . So, this will be equal to $y_{n+1} - 2y_n + y_{n-1}$ divided by h^2 .

So, these are the values we substitute in this formula.

(Refer Slide Time: 40:27)

A photograph of a whiteboard with handwritten mathematical formulas. The top formula is $y''(x_n) + f(x_n)y'(x_n) + g(x_n)y(x_n) = r(x_n), n = 1, \dots, N-1$. Below it are the approximations $y(x_n) \approx y_n$, $y'(x_n) \approx \frac{y_{n+1} - y_{n-1}}{2h}$, and $y''(x_n) \approx \frac{y_{n+1} - 2y_n + y_{n-1}}{h^2}$. A small NPTL logo is visible in the bottom left corner.

$$y''(x_n) + f(x_n)y'(x_n) + g(x_n)y(x_n) = r(x_n), n = 1, \dots, N-1$$
$$y(x_n) \approx y_n$$
$$y'(x_n) \approx \frac{y_{n+1} - y_{n-1}}{2h}$$
$$y''(x_n) \approx \frac{y_{n+1} - 2y_n + y_{n-1}}{h^2}$$

So, when you substitute you are going to have a relation which involves y_{n-1} , y_n and y_{n+1} .

(Refer Slide Time: 40:36)

$$\frac{y_{n-1} - 2y_n + y_{n+1}}{h^2} + f(x_n) \frac{y_{n+1} - y_{n-1}}{2h} + g(x_n) y_n = r(x_n),$$

$$n = 1, 2, \dots, N-1$$

$$\left(1 - \frac{h}{2} f_n\right) y_{n-1} + \left(-2 + h^2 g_n\right) y_n + \left(1 + \frac{h}{2} f_n\right) y_{n+1} = h^2 r_n,$$

$$n = 1, 2, \dots, N-1$$

So, we have this is the substitution for $y_{n-1} - 2y_n + y_{n+1}$ divided by h^2 plus $f(x_n)$ and then $y_{n+1} - y_{n-1}$ divided by $2h$ plus $g(x_n) y_n$ at x_n that is y_n is equal to $r(x_n)$ n is equal to 1 to up to n minus one.

So, we get $n - 1$ equations in $n - 1$ unknowns our $n - 1$, unknowns are going to be y_1, y_2 up to y_{N-1} . y_1 will be approximation to y at x_1 . Let us simplify, multiply throughout by h^2 collect the coefficients of y_{n-1} and y_n and y_{n+1} . So, it will become y_{n-1} you are multiplying by h^2 . So, from here it will be 1 from here it will be minus h by $2f_n$ f_n is nothing, but f of x_n into y_{n-1} plus coefficient of y_n from here it will be minus 2 and from here it will be $h^2 g_n$ plus coefficient of y_{n+1} from here, it is 1 and from here it is going to be $h^2 r_n$ y_{n+1} is equal to $h^2 r_n$ n varying from 1 to up to $n - 1$.

So, thus

(Refer Slide Time: 42:27)

$$\begin{aligned} & \left(1 - \frac{h}{2} f_n\right) y_{n-1} + \left(-2 + h^2 g_n\right) y_n \\ & + \left(1 + \frac{h}{2} f_n\right) y_{n+1} = h^2 r_n, \\ & \quad n = 1, 2, \dots, N-1 \\ & a_n y_{n-1} + d_n y_n + c_n y_{n+1} = h^2 r_n \\ & \quad n = 1, 2, \dots, N-1 \\ & n=1 \quad d_1 y_1 + c_1 y_2 = h^2 r_1 - a_1 \alpha \\ & n=N-1 \quad a_{N-1} y_{N-2} + d_{N-1} y_{N-1} = h^2 r_{N-1} - c_{N-1} \beta \end{aligned}$$

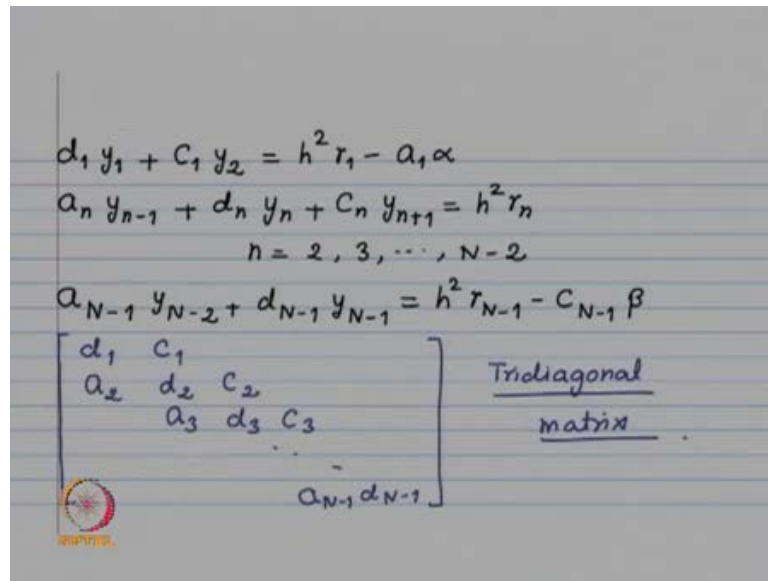

this for the sake of simplicity let me call this as a n the diagonal entries as d n and these values as c. So, we have got a system of the type a n y n minus 1 plus d n y n plus c n y n plus 1 is equal to h square r n if i look at n is equal to 1 when n is equal to 1 y 0 is given to us it is alpha.

So, I can take it on the other side. So, I get for n is equal to 1 it becomes d 1 y 1 plus c 1 y 2 is equal to h square r 1 minus a 1 times alpha. Similarly when I consider n is equal to capital N minus 1 y n plus 1 will be y capital N.

And y capital N is given to us y capital N is y at b that is equal to beta. So, let me take it on the other side. So, this is going to be the last equation a n minus 1 y n minus 2 plus d N minus 1 y N minus 1 is equal to h square r n minus 1 minus c n minus 1 beta. So, in each equation you have got diagonal entry and then 2 more entries and that is it.

So, thus

(Refer Slide Time: 44:08)

The image shows handwritten mathematical equations and a matrix on a lined background. The equations are:

$$d_1 y_1 + c_1 y_2 = h^2 r_1 - a_1 \alpha$$
$$a_n y_{n-1} + d_n y_n + c_n y_{n+1} = h^2 r_n$$
$$n = 2, 3, \dots, N-2$$
$$a_{N-1} y_{N-2} + d_{N-1} y_{N-1} = h^2 r_{N-1} - c_{N-1} \beta$$

Below the equations is a tridiagonal matrix:

$$\begin{bmatrix} d_1 & c_1 & & & \\ a_2 & d_2 & c_2 & & \\ & a_3 & d_3 & c_3 & \\ & & & \ddots & \\ & & & & a_{N-1} & d_{N-1} \end{bmatrix}$$

To the right of the matrix, the text "Tridiagonal matrix" is written and underlined.

our system is going to tri-diagonal. So, you have got this is going to be your coefficient matrix along the diagonal d_1, d_2, d_3 up to d_{n-1} , you will have 1 super diagonal.

And then you will have 1 sub diagonal and then we have looked at various methods of solving system of linear equations. So, 1 solves us system after solving the system you will get y_1, y_2 up to y_{n-1} , that was our m in solving that we said that y is our unknown solution and then we will try to find its approximation at some discrete points.

So, y at x_n we wanted to find. So, when you replace the derivatives by the difference formula or by numerical differentiation then you get a system of linear equation and then by a solving that you will get the value approximate values.

Now, I just want to recall recall the result about numerical differentiation.

(Refer Slide Time: 50:42)

Recall :

$$f(x) = f(a-h) + f[a-h, a+h](x-a+h) + f[a-h, a+h, x](x-a+h)(x-a-h)$$

$$f'(x) = f[a-h, a+h] + f[a-h, a+h, x, x](x-a+h)(x-a-h) + f[a-h, a+h, x] \{x-a-h + x-a+h\}$$

$$f'(a) = f[a-h, a+h] - h^2 f[a-h, a+h, a, a]$$

$$f'(a) \approx \frac{f(a+h) - f(a-h)}{2h}, \text{ error} = \frac{f^{(3)}(c)}{3!} h^2$$

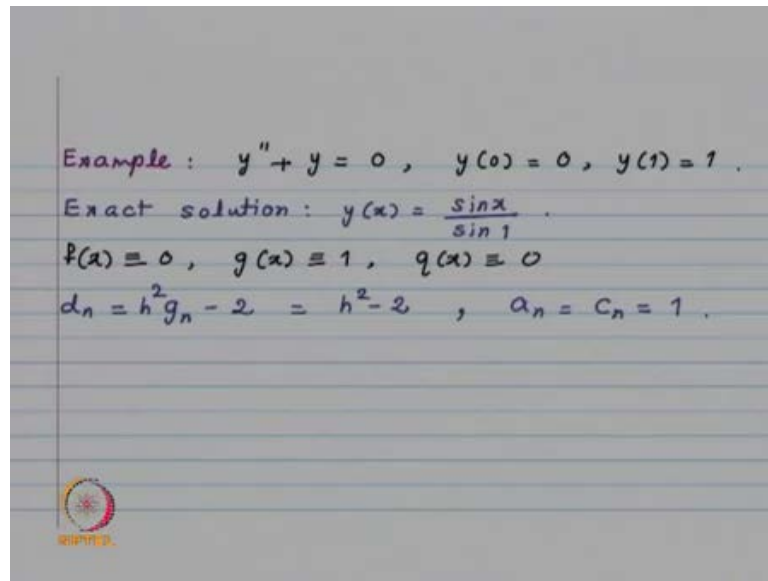

For numerical differentiation, what we had done was $f'(x)$ is going to be equal to $f'(a-h)$ plus divided difference based on $a-h$ and $a+h$ into $x-a+h$. So, this is a linear polynomial which interpolates the given function at $a-h$ and $a+h$.

And this is going to be the error term you take the derivative. So, $f'(x)$ will be equal to $f'(a-h)$ plus $f[a-h, a+h, x, x]$ multiplied by the product of these 2 terms, plus the divided difference and then you have to take the derivative of this. So, that is $x-a-h + x-a+h$ when you put x is equal to a this term will go away.

So, you get $f'(a)$ to be equal to $f'(a-h)$ plus $-h^2 f[a-h, a+h, a, a]$. So, thus $f'(a)$ is approximately is equal to this, with the error to be of the order of h^2 and then, similar if the case for the second derivative $f''(a)$.

So, if you consider the central difference formula then again the error is of the order of h^2 .

(Refer Slide Time: 47:10)

Example : $y'' + y = 0$, $y(0) = 0$, $y(1) = 1$.
Exact solution : $y(x) = \frac{\sin x}{\sin 1}$.
 $f(x) \equiv 0$, $g(x) \equiv 1$, $q(x) \equiv 0$
 $d_n = h^2 g_n - 2 = h^2 - 2$, $a_n = c_n = 1$.

Now, here is the example $y'' + y = 0$, $y(0) = 0$, $y(1) = 1$. So, that means, in our notation $f(x)$ is identically 0 there is no y'' term.

$G(x)$ which is coefficient of y that is 1 and $q(x)$ is equal to zero. So, the diagonal entries they are going to be equal to 0 d_n they are going to be equal to $h^2 g_n - 2$. So, that will be nothing, but $h^2 - 2$.

Whereas a_n and c_n these are equal to one. So, that is our tri diagonal system. So, thus . So, we have looked at now solution of differential equation the boundary value problem by finite difference method.

Finite difference method is a classical method now there is a finite element method. So, which has been now used successfully it competes now with finite difference method. The finite difference method has advantage of simplicity, that we just replaced the derivatives by numerical differentiation, here what we have done is we have replaced the derivatives by numerical differentiation with the error to be of the order of h^2 . So, whatever approximations by in which we have obtained again the error is going to be of the order of h^2 .

So, y at x_n minus y_n will be of the order of h^2 . So, if you want whatever accuracy you want you may have to choose h very small, if you choose h small it increases the size of your system of linear equations.

So, then other way is use some better formula. So, from the numerical differentiation use some better formula, but then that becomes complicated now the finite element method is one of the important methods, but we will not be doing it in this course.

So, now our next topic is going to be eigen value problem, eigen value problems like when you consider matrix of size five or bigger you cannot have a formula for eigen values. So, that is why one tries to find as much information of eigen value that is possible indirectly.

It is without finding and then we are going to consider some approximate methods for finding eigen values and eigen vector. So, that is the topic which we will start in our next lecture.

So, thank you .
