**Error in the Interpolating Polynomial**

Today, we are first going to prove Leibniz formula for divided differences, and then afterwards, we will consider error in the interpolating polynomial, and choice of interpolation points, such that one part of the error, it is minimized.

So, there is a Leibniz formula for the derivatives, and there is a relation between divided difference, and the derivative values, so what we do is we look at the Leibniz formula for the derivatives, write it in terms of the divided difference based on points which are repeated, and then try to write an analogous formula, and then give its proof.

(Refer Slide Time: 01:23)

Leibniz Formula for Derivatives

$$(fg)^{(n)}(x_0) = \sum_{r=0}^n \frac{n!}{r!(n-r)!} f^{(r)}(x_0) g^{(n-r)}(x_0)$$

$$f[\underbrace{x_0, x_0, \dots, x_0}_{n+1}] = \frac{f^{(n)}(x_0)}{n!}$$

$$(fg)[\underbrace{x_0, \dots, x_0}_{n+1}] = \sum_{r=0}^n f[\underbrace{x_0, \dots, x_0}_{r+1}] g[\underbrace{x_0, \dots, x_0}_{n-r+1}]$$

So, the Leibniz formula for derivatives is given by, if you have two functions  $f$  and  $g$ , which are  $n$  times differentiable, so the derivative of  $f$  into  $g$  at  $x_0$  is given by summation  $r$  goes from  $0$  to  $n$ ,  $n$  factorial divided by  $r$  factorial into  $n$  minus  $r$  factorial

and then  $r$ th derivative of  $f$  evaluated at  $x_0$  and  $n$  minus  $r$ th derivative of  $g$  evaluated at  $x_0$ .

So, the derivative of  $f$  into  $g$  is given in terms of the derivatives of  $f$  and derivatives of  $g$  involving the derivatives of order up to order  $n$ , the definition of divided difference  $f$  based on  $x_0$  which is repeated  $n$  plus 1 times that is  $f$   $n$   $x_0$  divided by  $n$  factorial, so divide by  $n$  factorial, so that the left hand side will be divided difference of  $f$  into  $g$  based on  $x_0$  repeated  $n$  plus 1 times.

(Refer Slide Time: 03:07)

$$(f g)[\underbrace{x_0, \dots, x_0}_{n+1}] = \sum_{r=0}^n \underbrace{f[x_0, \dots, x_0]}_{r+1} \underbrace{g[x_0, \dots, x_0]}_{n-r+1}$$

Question:

$$(f g)[x_0, \dots, x_n] = \sum_{r=0}^n f[x_0, \dots, x_r] g[x_r, \dots, x_n] ?$$

Now, this will be equal to summation  $r$  goes from 0 to  $n$ , we have divided by  $n$  factorial associate  $r$  factorial with  $f$   $r$   $x_0$ , so that will be divided difference of  $f$  based on  $x_0$  repeated  $r$  plus 1 times and associate  $n$  minus  $r$  factorial with  $g$   $n$  minus  $r$   $x_0$ , so that will be divided difference of  $g$  based on  $x_0$  repeated  $n$  minus  $r$  plus 1 times. Now, what we do is, here the points were repeated, so whether I can have a formula of the type  $x_0, x_1, x_n$ .

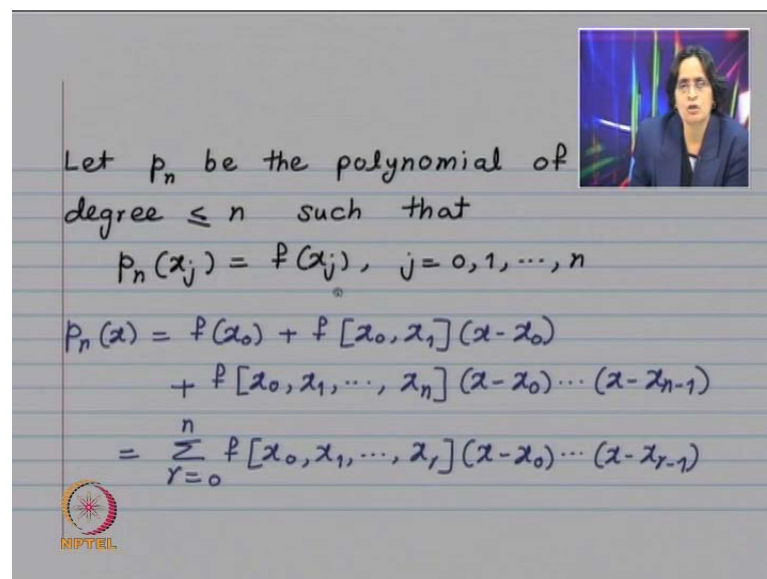

So, now these are  $n$  plus 1 distinct points, here you had  $n$  plus 1 coincident point, so whether this is equal to summation  $r$  goes from 0 to  $n$ , now first  $r$  plus 1 points so that will be  $x_0, x_1, x_r$  and last  $n$  minus  $r$  plus 1 points that will be  $x_r, x_{r+1}$  up to  $x_n$ . So, the question is whether this is true and the answer is yes and that is going to be the Leibniz formula for the divided differences, so what we are going to do is, we are going

to look at  $p_n$  to be interpolating polynomial for function  $f$  interpolating at the points  $x_0, x_1, \dots, x_n$ .

Then, we will look at another polynomial  $q_n$  which interpolates  $g$  at the same  $n+1$  point, such polynomials they are unique take their product, since  $p_n$  interpolates  $f$ ,  $q_n$  interpolates  $g$ ,  $p_n$  into  $q_n$  will interpolate the product function  $f$  into  $g$ . The definition of divided difference is look at coefficient of  $x$  raise to  $n$  in the unique interpolating polynomial.

So, now these  $p_n$  into  $q_n$  it is going to be an interpolating polynomial of our function  $f$  into  $g$ , but  $p_n$  into  $q_n$  will be a polynomial of degree less than or equal to  $2n$ , so this  $p_n$  into  $q_n$ , we will split in to two parts and from that we will extract a polynomial of degree less than or equal to  $n$  which interpolates the product function  $f$  into  $g$  and once we do that, then we will relate the divided difference of  $f$  into  $g$  with divided differences of  $f$  and of  $g$ .

(Refer Slide Time: 05:42)

Let  $p_n$  be the polynomial of degree  $\leq n$  such that

$$p_n(x_j) = f(x_j), \quad j = 0, 1, \dots, n$$

$$p_n(x) = f(x_0) + f[x_0, x_1](x-x_0) + f[x_0, x_1, \dots, x_n](x-x_0)\dots(x-x_{n-1})$$

$$= \sum_{r=0}^n f[x_0, x_1, \dots, x_r](x-x_0)\dots(x-x_{r-1})$$

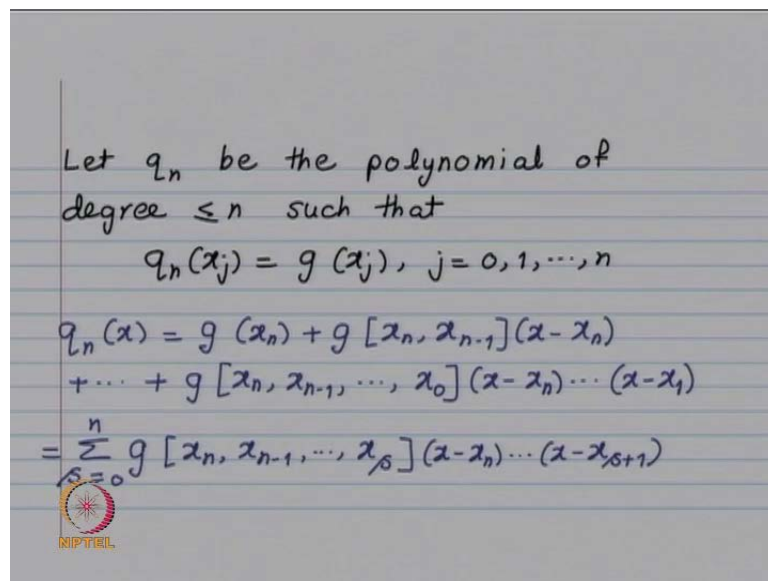

So, here is a polynomial  $p_n$  of degree less than or equal to  $n$ , such that  $p_n(x_j)$  is equal to  $f(x_j)$ . It is the unique polynomial, which interpolates our given function  $f$  at points  $x_0, x_1, \dots, x_n$ . Now, in the Newton form this polynomial is given by value of  $f$  at  $x_0$  plus divided difference based on  $x_0$  and  $x_1$  into  $x$  minus  $x_0$  and here it should be plus dot dot dot there will be some more terms, plus  $f$  of  $x_0, x_1, \dots, x_n$ ,  $x$  minus  $x_0, x$  minus  $x_1, \dots, x$  minus  $x_{n-1}$ , when you are taking the divided difference up to  $n$ , then you are multiplying by

$(x - x_0)(x - x_1) \dots (x - x_{n-1})$ , this is the Newton form of the interpolating polynomial  $p_n$ .

We can write it in compact form as summation  $r$  goes from 0 to  $n$ , divided difference based on  $x_0, x_1, \dots, x_r$  multiplied by  $(x - x_0) \dots (x - x_{r-1})$ , here you go up to  $x_r$  and here you go only up to  $x_{r-1}$ , so this is the interpolating polynomial of our function  $f$ .

(Refer Slide Time: 07:16)

Let  $q_n$  be the polynomial of degree  $\leq n$  such that

$$q_n(x_j) = g(x_j), \quad j = 0, 1, \dots, n$$

$$q_n(x) = g(x_n) + g[x_n, x_{n-1}](x - x_n) + \dots + g[x_n, x_{n-1}, \dots, x_0](x - x_n) \dots (x - x_1)$$

$$= \sum_{s=0}^n g[x_n, x_{n-1}, \dots, x_s](x - x_n) \dots (x - x_{s+1})$$

NIPTEIL

Now, we will look at similar polynomial for function  $g$ , so  $q_n$  is the unique interpolating polynomial, interpolating  $g$  at  $x_0, x_1, \dots, x_n$ , the interpolating polynomial is determined by the interpolation points, the order of the interpolation points does not matter, so for  $q_n(x)$  we will use the backward formula, that means we write it as  $q_n(x)$  is equal to  $g(x_n)$  plus divided difference of  $g$  based on  $x_n, x_{n-1}, \dots, x_0$  multiplied by  $(x - x_n) \dots (x - x_1)$ .

(Refer Slide Time: 08:34)

The image shows a whiteboard with handwritten mathematical formulas. On the left, there are two columns of points: the first column is labeled 'f' and contains points  $x_0, x_1, x_2, \dots, x_n$ ; the second column is labeled 'g' and contains points  $x_n, x_{n-1}, \dots, x_0$ . To the right of the 'f' column, the forward interpolation formula is written as  $p_n(x) = f(x_0) + f[x_0, x_1](x-x_0) + f[x_0, x_1, x_2](x-x_0)(x-x_1) + \dots + f[x_0, x_1, \dots, x_n](x-x_0)\dots(x-x_{n-1})$ . The word 'forward' is written above the formula. To the right of the 'g' column, the backward interpolation formula is written as  $q_n(x) = g(x_n) + g[x_n, x_{n-1}](x-x_n) + \dots + g[x_0, x_1, \dots, x_n](x-x_0)\dots(x-x_{n-1})$ . The word 'backward' is written above the formula. A hand holding a blue marker is visible at the bottom right of the whiteboard. In the bottom left corner of the whiteboard, there is a logo for NIPTEL.

So, here you go up to  $x_0$  then here you stop at  $x_1$ , so the points which we are taking they are the interpolation points taken in the reverse order, you have  $x_n, x_{n-1}$  up to  $x_0$ . What we had done was? When we looked at function  $f$ , then the interpolation points we took in the order  $x_0, x_1, x_2$  up to  $x_n$ . So our  $p_n(x)$  was  $f(x_0)$  then the two points  $x_0, x_1$  into  $(x-x_0)$  then  $x_0, x_1, x_2$  into  $(x-x_0)(x-x_1)$  and the last term is divided difference based on all these points, so it is  $x_0, x_1, \dots, x_n$  multiplied by  $(x-x_0)$  up to  $(x-x_{n-1})$  for the function  $g$  our points are going to be  $x_n, x_{n-1}, \dots, x_0$ .

So, the set is the same but the points we are taking in the reverse order, so  $q_n(x)$  will be equal to  $g(x_n)$  the first point, plus divided difference based on  $x_n, x_{n-1}$  and now  $x_{n-2}$ , so when we proceed in this form the last term is going to be  $x_0, x_1, \dots, x_n$  and then you will be multiplying by  $(x-x_n)$  up to  $(x-x_1)$ , so it is  $(x-x_n)\dots(x-x_1)$ .

I could have written  $q_n$  with the points to be taken in the order  $x_0, x_1, \dots, x_n$ , it is the same polynomial, it is just here I am using the forward formula and here I am using backward formula.

(Refer Slide Time: 11:05)

Let  $q_n$  be the polynomial of degree  $\leq n$  such that

$$q_n(x_j) = g(x_j), \quad j = 0, 1, \dots, n$$

$$q_n(x) = g(x_n) + g[x_n, x_{n-1}](x - x_n) + \dots + g[x_n, x_{n-1}, \dots, x_0](x - x_n) \dots (x - x_1)$$

$$= \sum_{s=0}^n g[x_n, x_{n-1}, \dots, x_s](x - x_n) \dots (x - x_{s+1})$$

(Refer Slide Time: 11:27)

$$p_n(x) = \sum_{r=0}^n f[x_0, \dots, x_r](x - x_0) \dots (x - x_{r-1})$$

$$q_n(x) = \sum_{s=0}^n g[x_n, \dots, x_s](x - x_n) \dots (x - x_{s+1})$$

$$p_n(x_j) = f(x_j), \quad q_n(x_j) = g(x_j),$$

$$j = 0, 1, \dots, n$$

$$(p_n q_n)(x_j) = p_n(x_j) q_n(x_j)$$

$$= f(x_j) g(x_j), \quad j = 0, 1, \dots, n$$

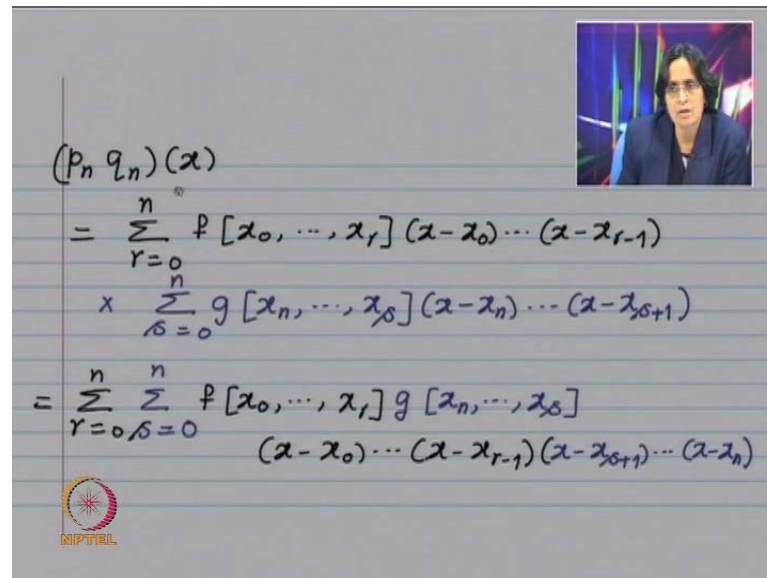

$$= (fg)(x_j)$$

So, we have  $q_n(x)$  to be equal to summation  $s$  going from zero to  $n$ ,  $g(x_n, x_{n-1}, \dots, x_s)$  multiplied by  $(x - x_n) \dots (x - x_{s+1})$ . Now, we are going to take product of these two polynomials, so  $p_n(x)$  is written in the forward fashion  $q_n(x)$  we are using the backward formula,  $p_n$  interpolates  $f$ ,  $q_n$  interpolates  $g$ , so when I take the product  $p_n$  into  $q_n$  of  $x_j$ , that will be nothing but  $p_n$  at  $x_j$  into  $q_n$  of  $x_j$ , which will be equal to  $f(x_j)$  into  $g(x_j)$ , so this will be equal to  $f(x_j)g(x_j)$ .

So  $p_n$  into  $q_n$  interpolates  $x_j$  at  $j$  is equal to 0, 1 up to  $n$ , the degree of  $p_n, q_n$  is going to be less than or equal to  $2n$ , in order to talk of the divided difference we will need an interpolating polynomial of degree less than or equal to  $n$ .

(Refer Slide Time: 12:26)

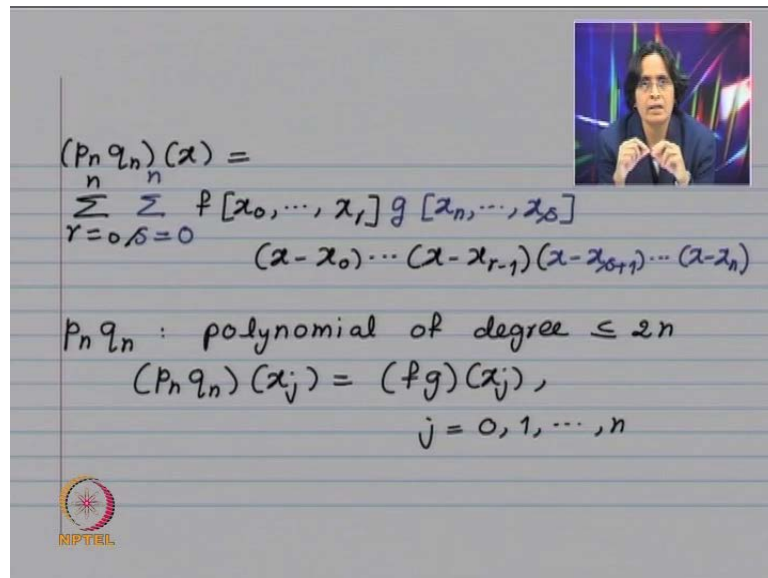

$$\begin{aligned}
 (p_n q_n)(x) &= \sum_{r=0}^n f[x_0, \dots, x_r] (x-x_0) \dots (x-x_{r-1}) \\
 &\quad \times \sum_{s=0}^n g[x_n, \dots, x_s] (x-x_n) \dots (x-x_{s+1}) \\
 &= \sum_{r=0}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] \\
 &\quad (x-x_0) \dots (x-x_{r-1}) (x-x_{s+1}) \dots (x-x_n)
 \end{aligned}$$

So, look at the product of this  $p_n$  into  $q_n$ , this is the formula for  $p_n$ , this is formula for  $q_n$ , you are taking their multiplication, so this will be summation  $r$  goes from 0 to  $n$  summation  $s$  going from 0 to  $n$ ,  $f$  of  $x_0, x_1, \dots, x_r$ ,  $g$  of  $x_n, x_{n-1}, \dots, x_s$  multiplied by  $x$  minus  $x_0, x_1, \dots, x_{r-1}$  and then  $x$  minus  $x_{s+1}$  up to  $x$  minus  $x_n$ ,  $r$  and  $s$  they take values from 0 to  $n$ .

So, when you have got  $r$  is equal to  $n$  and  $s$  is equal to  $n$ , you are going to have  $x$  minus  $x_0$  up to  $x$  minus  $x_{n-1}$  that means there are going to be  $n$  brackets and here it will be  $x$  minus  $x_n$  or here you should take  $s$  is equal to 0, the term corresponding to  $r$  is equal to  $n$  and  $s$  is equal to 0.

(Refer Slide Time: 14:15)

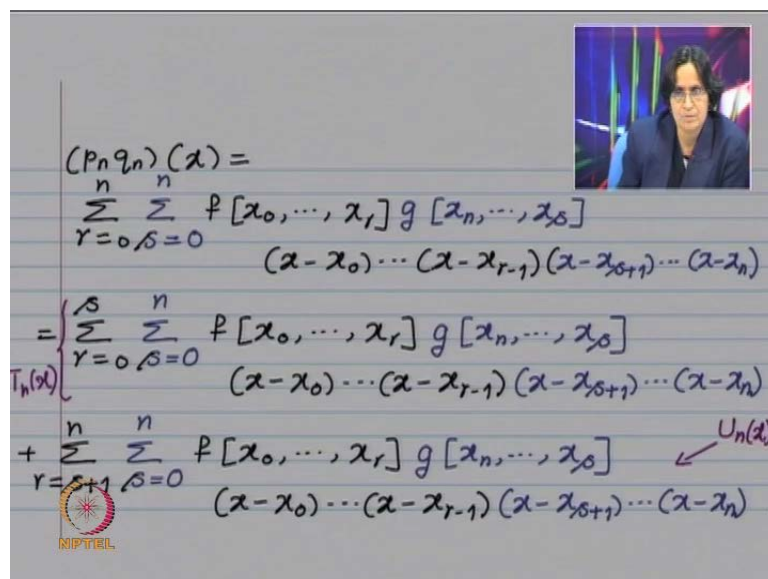

$$(P_n q_n)(x) = \sum_{r=0}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] \frac{1}{(x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)}$$

$P_n q_n$  : polynomial of degree  $\leq 2n$   
 $(P_n q_n)(x_j) = (fg)(x_j),$   
 $j = 0, 1, \dots, n$

So, that will be  $x$  minus  $x_1$  up to  $x$  minus  $x_n$ , so those will be also  $n$  bracket, so that is why  $p_n$  into  $q_n$  will be a polynomial of degree less than or equal to  $2n$ , it interpolates the given function  $f$  into  $g$ , we are interested in a polynomial of degree less than or equal to  $n$  interpolating the product function  $f$  into  $g$ .

So, as I said this is a polynomial of degree less than or equal to  $2n$ ,  $p_n$  into  $q_n$  is equal to  $f$  into  $g$  for  $j$  is equal to  $0$  up to  $n$ . Now, this polynomial we are going to split into two parts.

(Refer Slide Time: 14:59)

$$(P_n q_n)(x) = \sum_{r=0}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] \frac{1}{(x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)}$$

$$= \underbrace{\sum_{r=0}^s \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] \frac{1}{(x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)}}_{T_n(x)} + \sum_{r=s+1}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] \frac{1}{(x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)} \quad U_n(x)$$

So, one part will be a polynomial of degree less than or equal to  $n$ , which interpolates the product function  $f$  into  $g$ , other part will be such that it will vanish at our interpolation point, so the summation  $r$  goes from  $0$  to  $n$  and  $s$  goes from  $0$  to  $n$ . The first summation I split as summation  $r$  going from  $0$  to  $s$  and summation  $r$  going from  $s+1$  to  $n$ .

Now, if you look at the first part, it is going to be a polynomial of degree less than or equal to  $n$ , because look here, you have got  $x - x_0, x - x_{r-1}$  and then  $x - x_{s+1}$  and  $x - x_n$ , so when you have  $r$  is equal to  $s$  that is the maximum value  $r$  can take, you have here  $x - x_0, x - x_{s-1}$  and then here it is  $x - x_{s+1}, x - x_n$ , so the bracket  $x - x_s$  will be missing, so you are going to have only  $n$  brackets here and here you have got  $r$  is equal to  $s+1$  to  $n$ .  $x - x_0, x - x_{r-1}, x - x_{s+1}, x - x_n$ , so  $r$  is equal to  $s+1$  so that means it is going to be  $x - x_s$  and then you have got additional term.

(Refer Slide Time: 16:30)

First part:  $T(x)$

$$\sum_{r=0}^s \sum_{s=0}^n \alpha_n (x-x_0) \dots (x-x_{r-1}) (x-x_{s+1}) \dots (x-x_n)$$

$r \leq s$  :  $r = s$  :  $(x-x_0) \dots (x-x_{s-1}) (x-x_{s+1}) \dots (x-x_n)$   
at the most  $n$  brackets.

$T$  : poly. of degree  $\leq n$ .

So, here in the first part we have got summation  $r$  goes from  $0$  to  $s$ , summation  $s$  goes from  $0$  to  $n$ , some constant which is divided difference and then  $x - x_0, x - x_{r-1}$  and then  $x - x_{s+1}, x - x_n$ , so here the maximum value of  $r$  is  $s$ , so when you have got you have  $r$  to be less than or equal to  $s$  and for  $r$  is equal to  $s$ , you have got  $x - x_0, x - x_{s-1}, x - x_{s+1}, x - x_n$ , so at the most  $n$  brackets and hence, if I call this as  $T(x)$  this  $T$  will be a polynomial of degree less than or equal to  $n$ , so this was the first part.

(Refer Slide Time: 18:01)

Second Part:  $U(x)$

$$\sum_{r=s+1}^n \sum_{s=0}^n \beta_{r,s} (x-x_0) \cdots (x-x_{r-1}) (x-x_{s+1}) \cdots (x-x_n)$$

least value of  $r = s+1$ .

at least:

$$(x-x_0) \cdots (x-x_s) (x-x_{s+1}) \cdots (x-x_n)$$

$$r = s+2 \quad (x-x_0) \cdots (x-x_s) (x-x_{s+1})^2 \cdots (x-x_n)$$

$U(x_j) = 0, \quad j = 0, 1, \dots, n$

Now, the second part that is summation  $r$  going from  $s$  plus 1 to  $n$ , summation  $s$  goes from 0 to  $n$ , then you have got some constants  $\beta$ , so depending on say  $r$  and  $s$  and you are multiplying by  $x$  minus  $x_0$ ,  $x$  minus  $x_{r-1}$ ,  $x$  minus  $x_{s+1}$  up to  $x_n$ .

So, the least value of  $r$  is equal to  $s$  plus 1, so you have got at least the terms  $x$  minus  $x_0$ ,  $x$  minus  $x_s$ ,  $x$  minus  $x_{s+1}$  up to  $(x$  minus  $x_n)$ , so this will be there and in addition, if you are taking  $r$  is equal to  $s$  plus 2, so what will happen for  $r$  is equal to  $s$  plus 2 you are going to have  $x$  minus  $x_0$ ,  $x$  minus  $x_s$ ,  $x$  minus  $x_{s+1}$  square and then  $x$  minus  $x_n$ .

(Refer Slide Time: 20:01)

$$(p_n q_n)(x) = \sum_{r=0}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] (x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)$$

$$= \underbrace{\sum_{r=0}^s \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] (x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)}_{T_n(x)} + \sum_{r=s+1}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] (x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n) \quad U_n(x)$$

So thus, these many brackets they are going to be common and if I call these as u of x, then your u of x\_j is going to be 0, for j is equal to 0, 1 up to n, so we have p\_n into q\_n x is equal to the first part being a polynomial of degree less than or equal to n and the second part which vanishes at x\_j.

(Refer Slide Time: 20:16)

$$(p_n q_n)(x) = T_n(x) + U_n(x),$$

$$U_n(x) = \sum_{r=s+1}^n \sum_{s=0}^n f[x_0, \dots, x_r] g[x_n, \dots, x_s] (x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)$$

$$U_n(x_j) = 0, \quad j = 0, 1, \dots, n$$

$$\Rightarrow (fg)(x_j) = (p_n q_n)(x_j) = T_n(x_j), \quad j = 0, 1, \dots, n$$

So, U\_n at x\_j is equal to 0 for j going from 0, 1 up to n and p\_n into q\_n at x\_j was equal to f into g x\_j that we have seen, because p\_n interpolates f, q\_n interpolates g, p\_n into q\_n interpolates f into g, now p\_n into q\_n x\_j will be T\_n at x\_j plus U\_n at x\_j.

But,  $U_n$  at  $x_j$  is going to be 0, so  $p_n$  into  $q_n$   $x_j$  is equal to  $T_n x_j$ , so thus we have obtained a polynomial  $T_n$  of degree less than or equal to  $n$ , which interpolates our product function  $f$  into  $g$  at  $n+1$  points, so if I am interested in the divided difference of  $f$  into  $g$  based on  $x_0, x_1, x_n$ , then I can look at the coefficient of  $x$  raised to  $n$  in the polynomial  $T_n x$ , which is going to be the unique interpolating polynomial interpolating  $f$  into  $g$  at  $x_0, x_1, x_n$  and then that is going to give us the formula for divided difference of  $f$  into  $g$  in terms of divided differences of  $f$  and of  $g$ . So, here is  $T_n$  that is a polynomial of degree less than or equal to  $n$ , it is the interpolating polynomial.

(Refer Slide Time: 21:52)

$$T_n(x) = \sum_{r=0}^s \sum_{s=0}^n \frac{f[x_0, \dots, x_r] g[x_n, \dots, x_s]}{(x-x_0) \dots (x-x_{r-1})(x-x_{s+1}) \dots (x-x_n)}$$

$T_n$  : polynomial of degree  $\leq n$

$$T_n(x_j) = (fg)(x_j), \quad j=0, 1, \dots, n$$

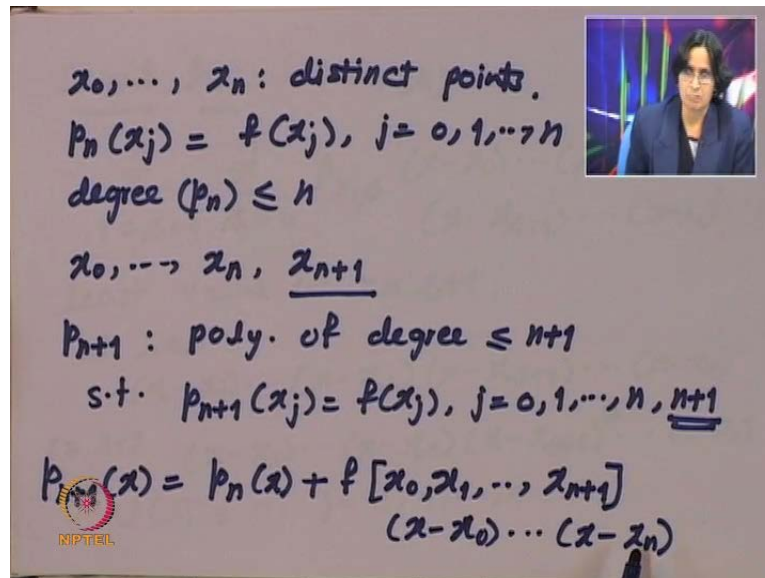

$$\Rightarrow (fg)[x_0, x_1, \dots, x_n] = \sum_{r=0}^n \frac{f[x_0, \dots, x_r] g[x_r, \dots, x_n]}{1}$$

So, coefficient of  $x$  raised to  $n$  in  $T_n x$ , if you want the coefficient of  $x$  raised to  $n$ , then  $r$  should take the maximum value which is  $s$ , then when  $r$  is equal to  $s$  you are going to have  $x$  minus  $x_0, x$  minus  $x_{s-1}, x$  minus  $x_{s+1}$  into  $x$  minus  $x_n$  and thus the coefficient of  $x$  raised to  $n$  will be given by this coefficient with  $r$  is equal to  $s$ .

So, coefficient of  $x$  raised to  $n$  in  $T_n x$  that is nothing but divided difference of  $f$  into  $g$  at  $x_0, x_1, x_n$ , which will be equal to coefficient of  $x$  raised to  $n$  in  $T_n x$  that will be when  $r$  is equal to  $s$ , so summation  $r$  going from 0 to  $n$ ,  $f$  of  $x_0, x_1, x_r$  and  $g$  of  $x_r, x_{r+1}, x_n$ .

The divided difference is independent of the order, so whether I write divided difference of  $g$  based on  $x_n, x_{n-1}, x_r$  or whether I write it as divided difference of  $g$  based on  $x_r, x_{r+1}, x_n$  then it is one and the same.

(Refer Slide Time: 24:38)

$x_0, \dots, x_n$ : distinct points.  
 $p_n(x_j) = f(x_j), j = 0, 1, \dots, n$   
 degree  $(p_n) \leq n$   
 $x_0, \dots, x_n, \underline{x_{n+1}}$   
 $p_{n+1}$ : poly. of degree  $\leq n+1$   
 s.t.  $p_{n+1}(x_j) = f(x_j), j = 0, 1, \dots, n, \underline{n+1}$   
 $p_{n+1}(x) = p_n(x) + f[x_0, x_1, \dots, x_{n+1}]$   
 $(x-x_0) \dots (x-x_n)$

So, now we have proved the Leibniz formula for divided differences, now next a important formula which we are going to prove that is the error in the interpolating polynomial, for proving the formula for error in the interpolating polynomial we are going to make use of the fact that using divided differences you can build polynomial, in the sense that, if you have a polynomial  $p_n$  interpolating the given function at  $x_0, x_1, x_n$  and if you add one more interpolating point  $x_{n+1}$ , then whatever is  $p_n(x)$  to that you add one more term and then that gives you the new interpolating polynomial.

So you have  $x_0, x_1$  up to  $x_n$ , these are distinct points and  $p_n$  at  $x_j$  is equal to  $f$  at  $x_j, j$  going from 0, 1 up to  $n$ , the degree of  $p_n$  is less than or equal to  $n$ .

Now, we add one more point, so you have got  $x_0, x_1, x_n$  and then  $x_{n+1}$ .  $p_{n+1}$  we want a polynomial of degree less than or equal to  $n+1$ , such that  $p_{n+1}(x_j)$  is equal to  $f(x_j)$  for  $j$  is equal to 0, 1 up to  $n$  and then additional point  $n+1$ .

So, we have seen that  $p_{n+1}(x)$  is equal to  $p_n(x)$  the earlier polynomial, plus divided difference based on  $x_0, x_1, x_{n+1}$  multiplied by  $(x-x_0) \dots (x-x_n)$ , so that is the formula for  $p_{n+1}$ .

Now, we are interested in the error in the interpolating polynomial, so that means we want a formula for  $f(x)$  minus  $p_n(x)$ , so what we are going to do is  $p_n(x)$  interpolating at  $x_0, x_1, \dots, x_n$ . So, first we will look at point  $\bar{x}$  which is such that  $\bar{x}$  is distinct from  $x_0, x_1, \dots, x_n$  and then consider  $p_{n+1}$  which interpolates  $f$  at  $x_0, x_1, \dots, x_n$  and then  $\bar{x}$ .

(Refer Slide Time: 27:13)

$$\begin{aligned}
 p_n(x_j) &= f(x_j), \quad j=0, 1, \dots, n \\
 \bar{x} &\neq x_j, \quad j=0, 1, \dots, n \\
 p_{n+1}(x_j) &= f(x_j), \quad p_{n+1}(\bar{x}) = f(\bar{x}) \\
 &\quad j=0, 1, \dots, n \\
 p_{n+1}(x) &= p_n(x) + \frac{f[x_0, \dots, x_n, \bar{x}]}{(x-x_0)\cdots(x-x_n)} \\
 f(\bar{x}) &= p_{n+1}(\bar{x}) = p_n(\bar{x}) \\
 &\quad + \frac{f[x_0, \dots, x_n, \bar{x}]}{(\bar{x}-x_0)\cdots(\bar{x}-x_n)}
 \end{aligned}$$

So we have got  $p_n$  is interpolating polynomial so  $p_n$  at  $x_j$  is equal to  $f$  of  $x_j$ ,  $j$  is equal to  $0, 1$  up to  $n$ .  $\bar{x}$  is such that it is not equal to  $x_j$ , for  $j$  is equal to  $0, 1$  up to  $n$  and let  $p_{n+1}$  be such that  $p_{n+1}(x_j)$  is equal to  $f(x_j)$  and  $p_{n+1}(\bar{x})$  is equal to  $f(\bar{x})$ . So,  $j$  is equal to  $0$  one up to  $n$ , so instead of taking  $x_{n+1}$  to be a fix point, after words I want  $\bar{x}$  to vary over the interval  $a, b$ , so that is why I am denoting it by  $\bar{x}$ .

Now,  $p_{n+1}(x)$  will be equal to  $p_n(x)$  plus divided difference based on  $x_0, x_1, \dots, x_n$  additional point which is  $\bar{x}$  multiplied by  $(x-x_0)(x-x_1)\cdots(x-x_n)$ , so this is my polynomial  $p_{n+1}$ .

What earlier I was calling  $x_{n+1}$ , I am calling it  $\bar{x}$  now we have  $f(\bar{x})$  is equal to  $p_{n+1}(\bar{x})$ , so this will be equal to  $p_n(\bar{x})$  wherever there is  $\bar{x}$  you have to write  $\bar{x}$  plus divided difference based on  $x_0, x_1, \dots, x_n, \bar{x}$  and now you have to replace  $x$  by  $\bar{x}$ , so it will be  $\bar{x} - x_0, \bar{x} - x_1, \dots, \bar{x} - x_n$ .

(Refer Slide Time: 29:35)

$$f(\bar{x}) - p_n(\bar{x}) = f[x_0, \dots, x_n, \bar{x}] (\bar{x} - x_0) \cdots (\bar{x} - x_n)$$

$$\bar{x} \neq x_j \quad \bar{x} \in [a, b]$$

$$f(x) - p_n(x) = f[x_0, \dots, x_n, x] (x - x_0) \cdots (x - x_n)$$

$$x \neq x_j, \quad j = 0, 1, \dots, n$$

Now, what I am going to do is look at  $f(\bar{x}) - p_n(\bar{x})$ , that is going to be this divided difference multiplied by  $(\bar{x} - x_0) \cdots (\bar{x} - x_n)$ ,  $f(\bar{x}) - p_n(\bar{x})$  is equal to  $f[x_0, \dots, x_n, \bar{x}] (\bar{x} - x_0) \cdots (\bar{x} - x_n)$ , so it will be  $f(\bar{x}) - p_n(\bar{x})$  is equal to  $f[x_0, \dots, x_n, \bar{x}] (\bar{x} - x_0) \cdots (\bar{x} - x_n)$ ,  $f(\bar{x}) - p_n(\bar{x})$  is equal to this divided difference, multiplied by the  $(\bar{x} - x_0) \cdots (\bar{x} - x_n)$ .

Now, for  $\bar{x}$  what we wanted was,  $\bar{x}$  should not be equal to  $x_j$ ,  $\bar{x}$  belongs to interval  $[a, b]$ , so this  $\bar{x}$  it is a dummy variable, so instead of  $\bar{x}$  if I write  $x$ , again it is going to be valid, so I will get  $f(x) - p_n(x)$  to be equal to  $f[x_0, \dots, x_n, x] (x - x_0) \cdots (x - x_n)$  when  $x \neq x_j$ , for  $j = 0, 1, \dots, n$ , so I have got an error for  $x \neq x_j$  to be equal to divided difference of  $f$  based on  $x_0, x_1, \dots, x_n$  and  $x$  multiplied by this product.

Now, what will happen if  $x$  is equal to  $x_j$ , if  $x$  is equal to  $x_j$ ,  $f(x) - p_n(x)$  is zero because  $p_n$  interpolates  $f$  at  $x_j$  and because of this presence of  $(x - x_0) \cdots (x - x_n)$  this bracket also or this product also will be zero.

So, both left hand side and right hand side they are zero and hence, I can say that this is going to be valid for all  $x$  belonging to interval  $[a, b]$ .

(Refer Slide Time: 32:00)

error

$$\begin{aligned} f(x) - p_n(x) &= f[x_0, x_1, \dots, x_n, x] (x-x_0) \dots (x-x_n) \\ &= \frac{f^{(n+1)}(c_x)}{(n+1)!} w(x) \end{aligned}$$

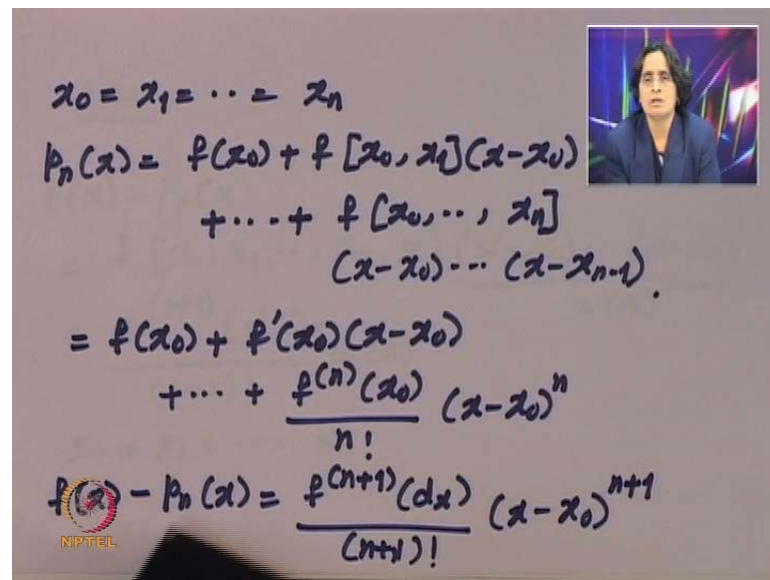

$x_0 = x_1 = \dots = x_n$

And thus we have got error to be  $f(x) - p_n(x)$  is equal to  $f(x_0, x_1, x_n, x)$  multiplied by  $(x - x_0)(x - x_1) \dots (x - x_n)$ , so this is the error in the interpolating polynomial, it is given by this suppose your function  $f$  is sufficiently differentiable that means  $n + 1$  times differentiable in this case.

Then what we can write this as  $f^{(n+1)}$  evaluated at some point  $d$  depending on  $x$  divided by  $(n + 1)!$ , let me call this function as  $w(x)$ , so multiplied by  $w(x)$ , suppose your points  $x_0, x_1, x_n$  instead of being distinct suppose they are coincident, then what we know is so suppose you have got  $x_0 = x_1 = \dots = x_n$ , then we have seen that the interpolating polynomial  $p_n$  is nothing, but the truncated Taylor's series.

(Refer Slide Time: 33:43)

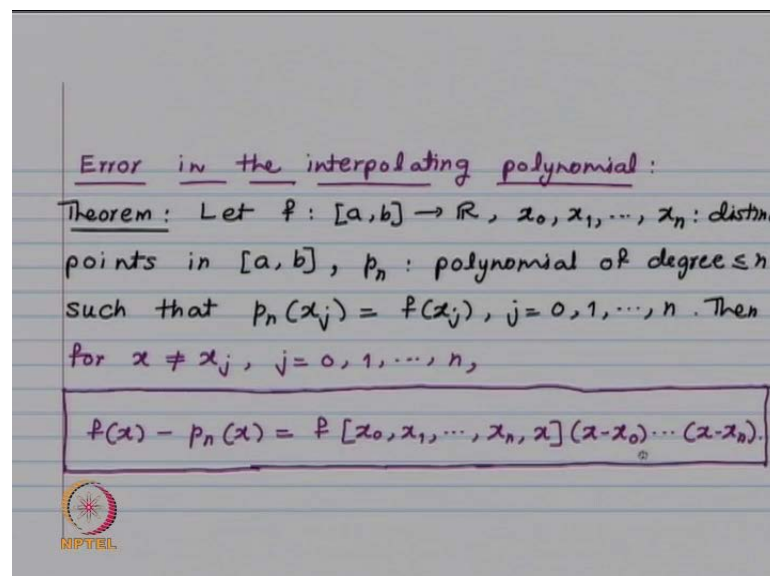

The image shows a handwritten derivation on a chalkboard. At the top right, there is a small inset video of a man with dark hair and a beard, wearing a blue jacket, looking towards the camera. The main text is written in black ink. It starts with the equation  $x_0 = x_1 = \dots = x_n$ . Below that, the interpolating polynomial  $p_n(x)$  is given as  $f(x_0) + f[x_0, x_1](x-x_0) + \dots + f[x_0, \dots, x_n](x-x_0)\dots(x-x_{n-1})$ . This is then simplified to  $f(x_0) + f'(x_0)(x-x_0) + \dots + \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n$ . Finally, the error term is given as  $f(x) - p_n(x) = \frac{f^{(n+1)}(\xi)}{(n+1)!}(x-x_0)^{n+1}$ . A small NIPTEL logo is visible in the bottom left corner of the chalkboard image.

So, we have if  $x_0$  is equal to  $x_1$  is equal to  $x_n$ , then when you consider  $p_n(x)$  that is given by  $f(x_0) + f[x_0, x_1](x-x_0) + \dots + f[x_0, x_1, x_n](x-x_0)(x-x_1)\dots(x-x_{n-1})$ .

So, if these are all equal, this is nothing but  $f(x_0) + f'(x_0)(x-x_0) + \dots + \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n$ , so this is the interpolating polynomial. And  $f(x) - p_n(x)$  this just now we saw that it is  $\frac{f^{(n+1)}(\xi)}{(n+1)!}(x-x_0)^{n+1}$ .

(Refer Slide Time: 35:22)

The image shows handwritten text on lined paper. The title is "Error in the interpolating polynomial:". Below it, the theorem is stated: "Theorem: Let  $f: [a, b] \rightarrow \mathbb{R}$ ,  $x_0, x_1, \dots, x_n$ : distinct points in  $[a, b]$ ,  $p_n$ : polynomial of degree  $\leq n$  such that  $p_n(x_j) = f(x_j)$ ,  $j = 0, 1, \dots, n$ . Then for  $x \neq x_j$ ,  $j = 0, 1, \dots, n$ ,". The error formula  $f(x) - p_n(x) = f[x_0, x_1, \dots, x_n, x](x-x_0)\dots(x-x_n)$  is enclosed in a purple rectangular box. A small NIPTEL logo is visible in the bottom left corner of the paper image.

So, the result which we have obtained for the error in the interpolating polynomial, that is the generalization of Taylor's theorem. So, here is the error in the interpolating polynomial that if  $f$  is from  $a, b$  to  $r, x_0, x_1, x_n$  these are distinct points in the interval  $a, b$ ,  $p_n$  is a polynomial of degree less than or equal to  $n$ , such that  $p_n(x_j)$  is equal to  $f(x_j)$  then  $f(x) - p_n(x)$ , the error consists of two parts, one is the divided difference multiplied by  $(x - x_0)(x - x_1)\dots(x - x_n)$ .

So, now that brings us to the question of choice of the interpolating points the error  $f(x) - p_n(x)$  that is equal to the divided difference based on  $x_0, x_1, x_n, x$  and multiplied by the function  $w(x)$  which consists of  $(x - x_0)(x - x_1)\dots(x - x_n)$ . Now, the function  $f$  is given to us what is in our hands, it is the choice of  $x_0, x_1, x_n$ .

So, the question one ask whether it is possible to choose this points  $x_0, x_1, x_n$ , such that the second part  $w(x)$  that can be minimized, so what we want is our  $x_0, x_1, x_n$  they should vary over our interval  $a, b$ , but they whether it is possible to choose them, so that the norm of  $w(x)$  that is minimized the infinity norm.

(Refer Slide Time: 37:22)

$$f(x) - p_n(x) = \frac{f[x_0, \dots, x_n, x]}{(x-x_0)\dots(x-x_n)} = \frac{f[x_0, \dots, x_n, x]}{w(x)}$$

Q.  $\min \{x_0, \dots, x_n\} \subset [a, b] \quad ||w||_\infty$  ?

$$w(x) = x^{n+1} - q_n(x) \quad \leftarrow q_n(x)$$

$$\min ||w||_\infty = \min ||x^{n+1} - q_n(x)||_\infty$$

$q_n \in P_n \leftarrow$  polys. of deg.  $\leq n$

So, we have  $f(x) - p_n(x)$  is equal to  $f(x_0, x_1, x_n, x)$  multiplied by  $(x - x_0)(x - x_1)\dots(x - x_n)$ , so this I am calling it to be  $w(x)$ , so the question is whether we can look at minimum of norm  $w$  infinity, the minimum will be taken over  $x_0, x_1, x_n$ , varying over interval  $a, b$  whether we can find such a minimum.

So, if I look at  $w(x)$ ,  $w(x)$  is going to be  $x$  raised to  $n$  and then or other it will be  $x$  raised to  $n$  plus 1, because you have got  $x - x_0, x - x_1, x - x_n$ , so it is going to be  $x$  raised to  $n$  plus 1 and then whatever remains it will be a polynomial of degree less than or equal to  $n$ , so it will be of the form  $a_0$  plus  $a_1 x$  plus  $a_n x$  raised to  $n$ .

Now, minimization of norm  $w$  infinity, we can say that it is same as minimization of norm of  $x$  raised to  $n$  plus 1 minus. Let, me call this function as  $q_n(x)$ , so  $q_n(x)$  its infinity norm where  $q_n$  belongs to the space of polynomials of degree less than or equal to  $n$ , so the minimization of this norm  $w$  infinity or the optimum choice of the interpolation points, these we have reduced to best approximation to the function  $x$  raised to  $n$  plus 1 from the space of polynomials of degree less than or equal to  $n$ .

(Refer Slide Time: 40:41)

Error in the interpolating polynomial

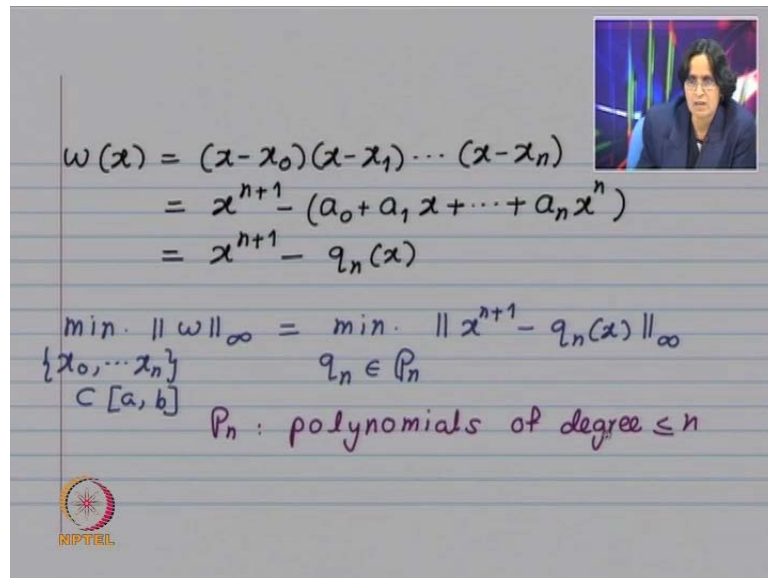

$$f(x) - p_n(x) = f[x_0, \dots, x_n, x] \frac{w(x)}{w'(x)}$$

$$\|f - p_n\|_\infty = \max_{x \in [a, b]} \frac{|f[x_0, \dots, x_n, x]|}{\|w\|_\infty}$$

Problem: To choose  $x_0, \dots, x_n$  such that  $\|w\|_\infty$  is minimized

Now, such a minimum exists and that minimum is going to be attained when you choose  $x_0, x_1, x_n$  to be the zeroes of the Chebyshev Polynomial. Now, I am not going to prove this fact, but what I am going to do is I am going to define the Chebyshev Polynomials and write down what are its roots.

(Refer Slide Time: 40:57)

$$\begin{aligned}w(x) &= (x-x_0)(x-x_1)\cdots(x-x_n) \\ &= x^{n+1} - (a_0 + a_1x + \cdots + a_nx^n) \\ &= x^{n+1} - q_n(x)\end{aligned}$$
$$\min_{\substack{\{x_0, \dots, x_n\} \\ \subset [a, b]}} \min_{q_n \in P_n} \|w\|_\infty = \min_{q_n \in P_n} \|x^{n+1} - q_n(x)\|_\infty$$

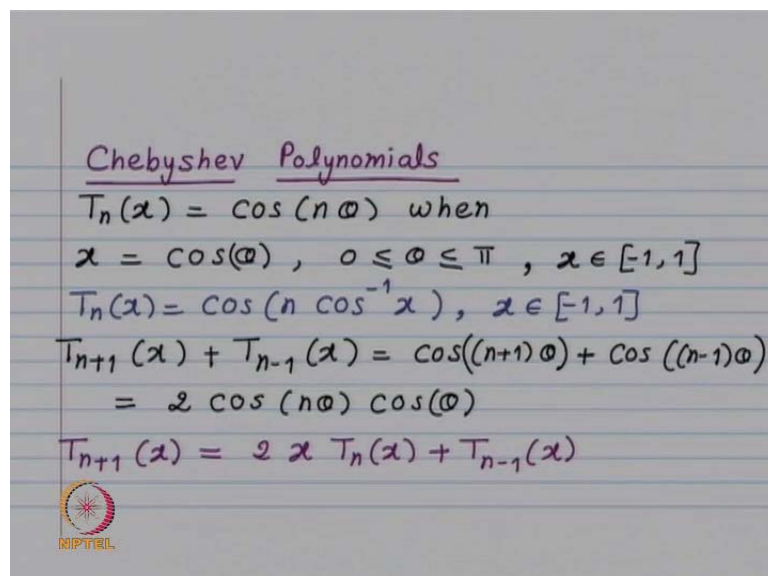

$P_n$ : polynomials of degree  $\leq n$

This is the error we are trying to minimize this w x it is infinity norm, so to choose  $x_0, x_1, x_n$ , such that norm w infinity is minimized, this w x is of the form  $x$  raise  $n$  plus  $1$  minus a polynomial degree less than or equal to  $n$ , that is  $x$  raise to  $n$  plus  $1$  minus  $q_n(x)$ .

So, the minimization of norm w infinity with the minimum taken over, so that  $x_0, x_1, x_n$  they vary over interval  $a, b$  that minimization problem is same as finding the best approximation to  $x$  raise to  $n$  plus  $1$  from the space of polynomials of degree less than or equal to  $n$ , so here are Chebyshev Polynomials.

(Refer Slide Time: 41:35)

Chebyshev Polynomials

$$T_n(x) = \cos(n\theta) \text{ when}$$
$$x = \cos(\theta), \quad 0 \leq \theta \leq \pi, \quad x \in [-1, 1]$$
$$T_n(x) = \cos(n \cos^{-1} x), \quad x \in [-1, 1]$$
$$\begin{aligned}T_{n+1}(x) + T_{n-1}(x) &= \cos((n+1)\theta) + \cos((n-1)\theta) \\ &= 2 \cos(n\theta) \cos(\theta)\end{aligned}$$
$$T_{n+1}(x) = 2x T_n(x) - T_{n-1}(x)$$

Further, to start with we define the Chebyshev Polynomial on interval minus 1 to 1 and if you consider a general interval  $a$  to  $b$ , then what we have to do is, consider a fine 1 to 1 on to map from minus 1 to 1 to interval  $a, b$  and take the image of the zeroes of the Chebyshev Polynomial defined on minus 1 to 1, so the Chebyshev Polynomial is defined as it is on the interval minus 1 to 1.

So, every point in the interval minus 1 to 1 is of the form  $\cos \theta$ , where  $\theta$  varies between 0 to  $\pi$ , so if  $x$  is equal to  $\cos \theta$ , then we define  $T_n x$  to be equal to  $\cos n \theta$  or you can write  $T_n x$  to be equal to  $\cos$  of  $n \cos^{-1} x$ ,  $x$  belonging to minus 1 to 1. So this is the Chebyshev Polynomial.

Using the trigonometric identities, we can use the we can prove a recurrence relation here this plus should be minus, so when I look at  $T_{n+1} x$  plus  $T_{n-1} x$ , it is going to be by definition  $\cos$  of  $n+1 \theta$  plus  $\cos$  of  $n-1 \theta$ .

Now,  $\cos$  of  $n+1 \theta$  will be  $\cos n \theta \cos \theta$  minus  $\sin n \theta \sin \theta$ , similar formula for  $\cos$  of  $n-1 \theta$ , so the  $\sin$  term gets cancelled and you are left with two  $\cos n \theta \cos \theta$ ,  $\cos n \theta$  is  $T_n x$  and  $\cos \theta$  is  $x$ , so  $T_{n+1} x$  will be  $2x T_n x$  and then you are taking here, so this should be minus, so minus  $T_{n-1} x$

Now, using this a recurrence relation what one can show is that  $T_n x$  is going to be a polynomial of exact degree  $n$  and its leading coefficient is going to be  $2^{n-1}$ , so  $T_n$  will be a polynomial of degree  $n$ , if it is a polynomial of degree  $n$  then we know that it is going to have  $n$  roots.

Now, these  $n$  roots in general when we say that a polynomial of degree  $n$  has  $n$  roots, the roots can be repeated in that case you have to count a root according to its multiplicity, but this Chebyshev Polynomial it has  $n$  distinct roots. See our minimization problem is minimizing over a distinct set of points, so whatever solution we get using this best approximation that again should give us  $n$  distinct points and that is what happens that the  $T_n x$ , the Chebyshev Polynomial which is of degree  $n$ , we show that it has got  $n$  roots  $n$  distinct roots.

(Refer Slide Time: 45:18)

$T_n(x) = \cos(n\theta)$  when  $x = \cos\theta$   
 $T_0(x) = 1$ ,  $T_1(x) = x$   
 $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$   
 $T_{n+1}$ : polynomial of degree  $n+1$   
with the leading coefficient  $2^n$ .  
Proof is by induction.  
True for  $n=0, 1$ . Then use  
recurrence formula

So  $T_{n+1}(x)$  is equal to  $2xT_n(x) - T_{n-1}(x)$ , if you put  $n$  is equal to 0 then  $\cos$  of 0 is 1, so  $T_0(x)$  is going to be constant function 1, when  $n$  is equal to 1,  $T_1(x)$  will be  $\cos\theta$ ,  $\cos\theta$  is  $x$ , so  $T_1(x)$  is equal to  $x$  and then the recurrence relation  $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$  we have specified  $T_0$  and  $T_1$ , now we can calculate  $T_2$ ,  $T_3$  and so on. Now,  $T_0$  is a constant polynomial  $T_1$  is a linear polynomial.

When you will look at  $T_2(x)$  then you have got  $2x$  into  $x$ , so that will be a polynomial of degree 2, so by induction one can show that  $T_{n+1}$  will be a polynomial of degree  $n+1$  and the leading coefficient is going to be  $2^n$ .

(Refer Slide Time: 46:42)

Roots of the Chebyshev Polynomial

$$T_n(x) = \cos(n\theta) \quad \text{when } x = \cos\theta$$
$$\cos(n\theta) = 0 \quad \text{if } n\theta = \frac{\pi}{2} + m\pi,$$
$$m = 0, \pm 1, \pm 2, \dots$$

Distinct roots :  $\cos(\theta)$  with

$$n\theta = \frac{\pi}{2}, \frac{\pi}{2} + \pi, \dots, \frac{\pi}{2} + (n-1)\pi,$$
$$\theta = \frac{1}{n} \left( \frac{\pi}{2} + m\pi \right), \quad m = 0, 1, \dots, (n-1)$$

So, it is true for  $n$  is equal to 0 to 1 and using the recurrence formula, it is easy show that the leading coefficient will be 2 raise to  $n$ . Now, we look at the roots of the Chebyshev Polynomial, so  $T_n x$  is equal to  $\cos n \theta$ ,  $\cos n \theta$  will be 0, if  $n \theta$  is equal to  $\pi$  by 2 plus  $m \pi$ , where  $m$  can take value 0 plus or minus 1, plus or minus 2 and so on, but all these values they will not give us distinct roots, so the distinct roots they are given by  $n \theta$  is equal to  $\pi$  by 2 plus  $\pi$  by 2 plus  $\pi$  plus  $\pi$  by 2 plus  $n$  minus 1  $\pi$ .

(Refer Slide Time: 47:39)

Roots of  $T_n(x)$  :  $\cos\theta$  with

$$\theta = \frac{1}{n} \left( \frac{\pi}{2} + m\pi \right), \quad m = 0, 1, \dots, n-1$$
$$= \frac{(2m+1)\pi}{2n}$$

Divide upper part of the unit circle into  $n$  equal parts :  $0, \frac{\pi}{n}, \frac{2\pi}{n}, \dots, \frac{n\pi}{n}$

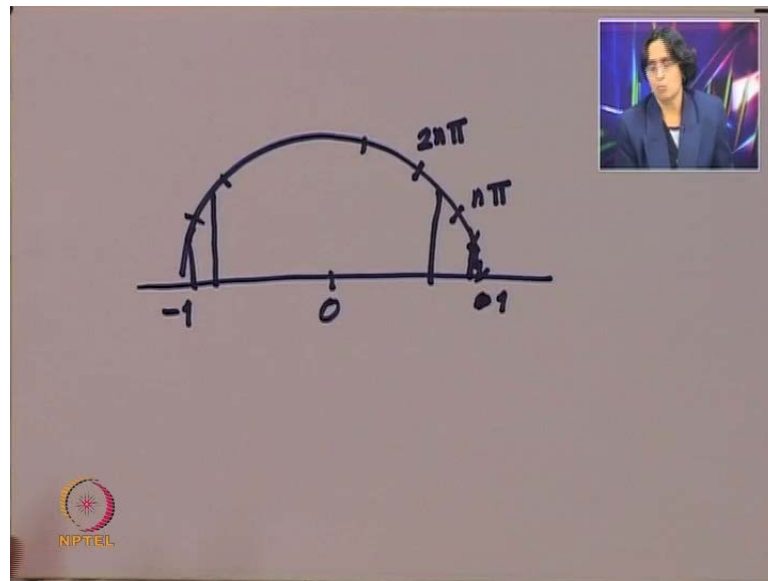

Take Midpoints :  $\frac{\pi}{2n}, \frac{3\pi}{2n}, \dots, \frac{(2n-1)\pi}{2n}$

Project onto  $[-1, 1]$

And that means theta will be equal to  $1$  upon  $n$  into  $\pi$  by  $2$  plus  $m \pi$  or that means  $2m$  plus  $1$   $\pi$  by  $2n$  for  $m$  is equal to  $0, 1$  up to  $n$  minus  $1$ , when  $m$  is equal to  $n$  then you get again the same root, so the roots of  $T_n(x)$  they are given by when theta is equal to  $1$  by  $n$   $\pi$  by  $2$  plus  $m \pi$ , so that is  $2m$  plus  $1$   $\pi$  by  $2n$ . Now, these can be interpreted as divide the upper part of the unit circle into  $n$  equal parts.

(Refer Slide Time: 48:13)

So, that means we are taking the points to be  $0$   $\pi$  by  $n$ ,  $2 \pi$  by  $n$ ,  $n \pi$  by  $n$ , take the midpoints and project on to  $-1$  to  $1$ , so you have got a unit circle look at its upper arc then this is going to be corresponding to  $0$ , this will be  $n \pi$ , this will be  $2 n \pi$  and so on.

You look at the midpoint you project on to  $-1$  to  $1$ , this is  $0$ , so this is  $-1$ , this is  $1$ , you have midpoint here, you draw it here you project, so like that you are going to get the Chebyshev points or zeroes of the Chebyshev Polynomial and these are the ones which will minimize our norm of  $w$ .

So, this is all for today's lecture and we will continue in the next lecture the study of our interpolating polynomials, I will state a result about the convergence of polynomials or other non-convergence of polynomials and thank you.
