Piecewise Polynomial Approximation

We are considering Piecewise Polynomial Approximation, our function f is defined on interval a, b closed and bounded interval a, b taking real values, we divide this interval into n equal parts. So, each sub interval is going to have length h , which is equal to b minus a divided by n , we fix k to be the degree of the polynomial, and then, on each interval we are going to fit a polynomial of degree less than or equal to k .

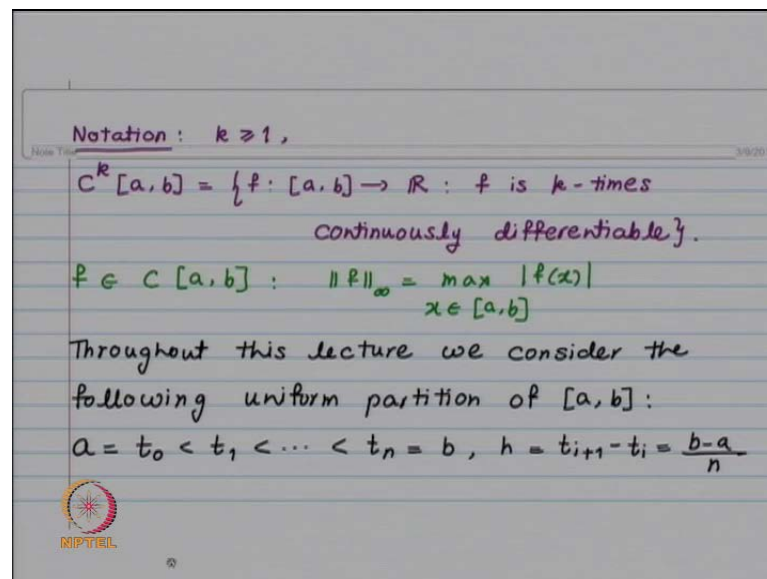

We have already considered the case of Piecewise Linear Interpolation, in that case, we had considered the interpolation points to be the partition points, so there are n plus 1 partition points, we are dividing the interval into n equal parts, so there are n plus 1 partition points, so far each interval t_i to t_{i+1} , we look at the value of the function at t_i and value at t_{i+1} and join it by straight line, so that gives us polynomial of degree less than or equal to 1.

Because, we are considering the interpolation points to be the end points of the interval, our function which is a Piecewise Linear Function, it is going to be a continuous function, and last time we saw that the maximum error norm of f minus p_n , its maximum norm or infinity norm is less than or equal to constant times h square, $h \times b$ minus a by n b minus a is fixed so as n tends to infinity h square will tend to 0 and error will tend to 0.

So, thus the degree of the polynomial in each sub interval was fixed to be less than or equal to 1 and then we increase the number of intervals and then under the assumption of function to be two times continuously differentiable we have proved the convergence of Piecewise Linear Interpolation.

Today, we are going to consider Piecewise Quadratic Interpolation and Piecewise Cubic Interpolation. We will show that in the case of Piecewise Quadratic Interpolation, the maximum error is going to be less than or equal to constant times h cube, so instead of h square we get h cube, so we have got faster convergence and in case of Piecewise Cubic we will get the maximum error to be less than or equal to constant times h raise to 4, so still faster convergence.

(Refer Slide Time: 03:55)

Now, let me consider the notations, which we are going to use so for k bigger than or equal to 1. $C^k[a, b]$ is going to consist of functions, which are k times continuously differentiable on interval a, b . This is going to be a vector space.

For a continuous function we have already defined the maximum norm that is maximum of $\text{mod } f(x), x \text{ belonging to } a, b$.

Throughout this lecture we are going to consider the following uniform partition of interval a, b , which is $a = t_0 < t_1 < \dots < t_n = b$, for i is equal to 0 1 up to n minus 1, $t_{i+1} - t_i$ which is equal to h , that is going to be equal to $\frac{b-a}{n}$.

Let us, recall the error in the interpolating polynomial, I had told you that this is the very important relation, so p_n is a polynomial of degree less than or equal to n , interpolating the given function at $n+1$ points x_0, x_1, \dots, x_n , then we have got an expression for

the error $f(x) - p_n(x)$ and if the function f is $n+1$ times differentiable, then we get the error in terms of the derivative of the function evaluated at some point.

(Refer Slide Time: 05:43)

Error in $P_n(x)$

$f: [a, b] \rightarrow \mathbb{R}$, x_0, x_1, \dots, x_n : distinct points

P_n : polynomial of degree $\leq n$ such that

$$P_n(x_j) = f(x_j), \quad j = 0, 1, \dots, n$$

$$f(x) - P_n(x) = f[x_0, x_1, \dots, x_n, x] (x-x_0) \dots (x-x_n)$$

$f \in C^{n+1}[a, b] \Rightarrow$

$$f(x) - P_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!} (x-x_0) \dots (x-x_n)$$

The error consists of 2 parts, it consists of divided difference $f[x_0, x_1, \dots, x_n, x]$ which if the function is $n+1$ times differentiable, then it is going to be equal to $n+1$ st derivative evaluated at some point c , that point c is going to depend on x , it also depends on x_0, x_1, \dots, x_n but x_0, x_1, \dots, x_n are fixed and x varies over interval a, b . So, this is 1 part and other part is the function $w(x)$ that is $(x-x_0)(x-x_1)\dots(x-x_n)$.

Last time we have seen that maximum norm of w is minimized by choosing x_0, x_1, \dots, x_n to be Chebyshev points. Now, today we are going to replace the interval a, b by interval t_i to t_{i+1} and in each polynomial in each subinterval we are going to have a polynomial of degree less than or equal to k , so we are going to join 2 polynomials together.

(Refer Slide Time: 07:19)

$$p_0(x) = a_0 + a_1 x, \quad x \in [0, 1]$$
$$q_0(x) = b_0 + b_1 x, \quad x \in [1, 2]$$

0 1 2

$$p_0(1) = q_0(1) : \quad a_0 + a_1 = b_0 + b_1$$
$$b_1 = a_0 + a_1 - b_0$$
$$p_0'(1) = q_0'(1) \Rightarrow a_1 = b_1$$
$$p_0'(x) = a_1, \quad q_0'(x) = b_1$$
$$a_0 = b_0$$
$$a_1 = b_1$$

Single polynomial.

Let us look at first the case of linear polynomial, so let $p_0(x)$ to be a_0 plus $a_1 x$, x belongs to 0 to 1, then let $q_0(x)$ to be equal to b_0 plus $b_1 x$, x belonging to 1 to 2.

So, we have interval 0, 1 and 2, if we do not impose any continuity condition at 1 then we have got 4 constants which can vary independently, so a_0 , a_1 , b_0 , b_1 .

Suppose we impose continuity that means we want p_0 at 1 should be equal to q_0 at 1, the problem of continuity comes only at the partition points, otherwise in the interval 0 to 1 p_0 being a polynomial, it is infinitely many times differentiable in the interval 1 to 2, the polynomial q_0 is going to be infinitely many times differentiable, so the question is whether the values at 1 whether they match.

So, that gives us a_0 plus a_1 is equal to b_0 plus b_1 , so that means now if I fix a_0 , a_1 and b_0 then I have no choice for b_1 , if I want the function which is formed by p_0 and q_0 to be continuous, then b_1 has to satisfy a_0 plus a_1 minus b_0 .

So, earlier we could vary a_0 , a_1 , b_0 , b_1 independently, now we can vary only 3 constants independently a_0 , a_1 and b_0 and then b_1 is determined in terms of a_0 , a_1 and b_0 , then suppose we want the derivatives to be continuous, so we want p_0' at 1 is equal to q_0' at 1, p_0' at x is equal to a_1 , q_0' at x is equal to b_1 and hence we get a_1 to be equal to b_1 .

Now, we have two relations, we have got this relation and we have got this relation, so from these two relations 1 concludes that a_0 has to be equal to b_0 , a_1 has to be equal to b_1 that means it is a single polynomial.

So, if we look at 2 polynomials of degree less than or equal to 1, then we can ask the resulting function to be continuous and still retain the Piecewise nature, but if we ask the function to be continuous and differentiable then it becomes the single polynomial.

(Refer Slide Time: 11:17)

$$\begin{aligned}
 p_0(x) &= a_0 + a_1 x + a_2 x^2, \quad x \in [0, 1] \\
 q_0(x) &= b_0 + b_1 x + b_2 x^2, \quad x \in [1, 2] \\
 \text{Continuity at } 1: & \quad a_0 + a_1 + a_2 = b_0 + b_1 + b_2 \\
 & \quad \text{5 constants: independent} \\
 p_0'(1) = q_0'(1): & \quad a_1 + 2a_2 = b_1 + 2b_2 \\
 p_0''(1) = q_0''(1) \Rightarrow & \quad 2a_2 = 2b_2 \quad \downarrow \\
 & \quad \downarrow \quad \downarrow \\
 & \quad b_2 = a_2, \quad b_1 = a_1, \quad b_0 = a_0.
 \end{aligned}$$

Next, let us look at the case of quadratic polynomials, so look at $p_0(x)$ to be equal to a_0 plus $a_1 x$ plus $a_2 x^2$, x belonging to 0 to 1 and $q_0(x)$ to be equal to b_0 plus $b_1 x$ plus $b_2 x^2$, x belonging to 1 to 2.

So, we have got 6 constants which can vary independently, continuity at point 1 implies that a_0 plus a_1 plus a_2 has to be equal to b_0 plus b_1 plus b_2 , so that means we have got only 5 constants which are independent.

Then, suppose we want p_0' at 1 is equal to q_0' at 1 then we have a_1 plus $2a_2$ should be equal to b_1 plus $2b_2$, so 1 more degree of liberty is lost.

If, we say that $p_0''(1)$ is equal to $q_0''(1)$, then this will imply that $2a_2$ should be equal to $2b_2$, so thus from here we have got b_2 is equal to a_2 , from here we get b_1 to be equal to a_1 and from here we get b_0 to be equal to a_0 .

(Refer Slide Time: 13:22)

Quadratic polynomials:

$$p_2(x) = a_0 + a_1x + a_2x^2, \quad q_2(x) = b_0 + b_1x + b_2x^2$$
$$p_2: [0, 1] \rightarrow \mathbb{R}, \quad q_2: [1, 2] \rightarrow \mathbb{R}$$

Continuity: $p_2(1) = q_2(1) \Rightarrow a_0 + a_1 + a_2 = b_0 + b_1 + b_2$

Continuity of the derivative:

$$p_2'(1) = q_2'(1) \Rightarrow a_1 + 2a_2 = b_1 + 2b_2$$

Continuity of the second derivative:

$$p_2''(1) = q_2''(1) \Rightarrow 2a_2 = 2b_2 \quad \text{Same Polynomial}$$

NPTEL

So, as in the case of the Piecewise Linear Polynomials, if you say that 2 quadratic polynomials p_2 and q_2 , they should together form a 2 times continuously differentiable function, in that case it becomes a single polynomial defined on these 2 interval, so if we want to retain the Piecewise structure, then for quadratic polynomial we can go up to the continuity of the derivative.

If, we increase the degree of the polynomial that means if we consider 2 cubic polynomials, then we can demand that the resulting function should be two times differentiable and still we can have two different cubic polynomials respectively on the interval 0 to 1 and interval 1 to 2.

If for cubic polynomials we ask for the function to be continuous first derivatives, second derivative and third derivative to be continuous, then it will reduce to a single cubic polynomial.

So, when we demand the continuity or the continuity of the derivatives, then for each of this demand the degree of liberty gets reduced by 1.

So, now we are going to here we had considered only 2 polynomials, now we are going to consider n intervals and on each interval we consider a polynomial.

So, first we are going to look at the dimension of such a space and then Piecewise Linear case we have already considered, so we will go to Piecewise Quadratic and Piecewise Cubic.

(Refer Slide Time: 16:03)

Piecewise polynomial space

$$a = t_0 < t_1 < \dots < t_n = b.$$

$$X_n = \{g : [a, b] \rightarrow \mathbb{R} : g|_{[t_i, t_{i+1}]} \text{ poly. of degree } \leq k\}.$$

dimension of $X_n = n(k+1)$

$$Y_n = \{g \in C[a, b] : g|_{[t_i, t_{i+1}]} \text{ polynomial of degree } \leq k\}$$

dimension of $Y_n = n(k+1) - (n-1) = nk+1$

$$Z_n = \{g \in C^1[a, b] : g|_{[t_i, t_{i+1}]} \text{ polynomial of degree } \leq k\}$$

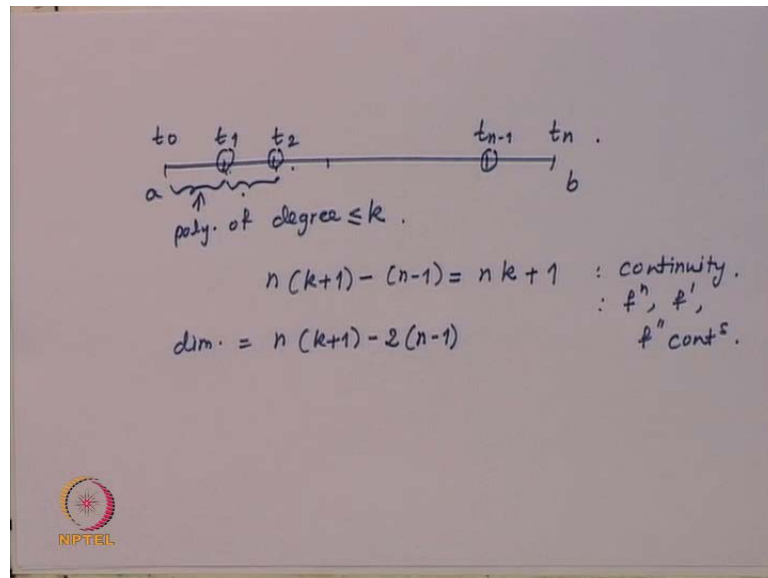

dimension of $Z_n = n(k+1) - 2(n-1) = nk - n + 2$

So, as I said our interval a, b is going to be divided into n equal parts and then you consider X_n to be set of all f or set of all g defined on interval a, b such that restriction of g to interval t_i to t_{i+1} is a polynomial of degree less than or equal to k .

We have got n intervals, in each interval it is a polynomial of degree less than or equal to k , that means we have got $k+1$ coefficients at our disposal, so total there are going to be $n(k+1)$ and that is going to be the dimension of the space X_n .

If we consider the space Y_n , where once again g restricted to t_i to t_{i+1} is a polynomial of degree less than or equal to k , but we impose the function to be continuous.

(Refer Slide Time: 17:07)

So, we have got, this is our interval a, b then we are subdividing into n equal parts, so this is $t_0, t_1, t_2, t_{n-1}, t_n$, here it is a polynomial of degree less than or equal to k .

So, we saw that the total degrees of liberty they are n into k plus 1 , now we will want these 2 polynomials to be continuous, so that will impose 1 constraint, then continuity at t_2 and continuity at t_{n-1} . So, we are imposing total n minus 1 constraint, so it will be minus n minus 1 and thus, we get the dimension to be equal to n k plus 1 , so this is if you are assuming continuity.

If we want the function, its derivative and f'' to be continuous then the dimension will be equal to n into k plus 1 minus at each point t_1, t_2, t_{n-1} we are putting 2 constraints, so that will be minus 2 into n minus 1 , so that will be the dimension of the space, so this was general case.

Now, let me recall the Piecewise Linear Continuous Polynomials. We have got n intervals in each interval linear, means we have got two coefficients so it is 2 into n , at interior nodes the continuity considerations so they are n minus 1 t_1, t_2, t_{n-1} .

So, the dimension of the space is $2n$ minus n minus 1 , so that is going to be n plus 1 . So, this is going to be dimension of our vector space which consists of Piecewise Linear Continuous Functions.

If we look at the value of the function f at the partition points that means t_0, t_1 up to t_n , so these partition points they are n plus 1 in number, so if we try to determine a Piecewise Linear Continuous Function which matches with the given function at t_0, t_1 up to t_n , then such a function is going to be unique.

(Refer Slide Time: 20:26)

Linear Polynomial Interpolation

$f: [a, b] \rightarrow \mathbb{R}$, $p_1(x) = a_0 + a_1x$ such that
 $p_1(a) = f(a)$, $p_1(b) = f(b)$.

$p_1(x) = f(a) + f[a, b](x-a)$

Let f be twice differentiable. Then

$f(x) - p_1(x) = f[a, b, x](x-a)(x-b) = \frac{f''(c_x)}{2}(x-a)(x-b)$.

$\Rightarrow \max_{x \in [a, b]} |f(x) - p_1(x)| = \|f - p_1\|_\infty \leq \frac{\|f''\|_\infty}{2} \left(\frac{b-a}{2}\right)^2$

This part we had seen last time that for linear polynomial interpolation norm of f minus p_1 its infinity norm is less than or equal to norm f double dash infinity divided by 2 into b minus a by 2 square. Our function is going to be linear on each interval t_i to t_{i+1} , so this bound we will write for the interval t_i to t_{i+1} and the bound will be norm f double dash infinity norm divided by 2 b minus a will be replaced by h by 2 square.

(Refer Slide Time: 21:43)

Let $f \in C^2[a, b]$. $h = \frac{b-a}{n} = t_{i+1} - t_i$
 For $x \in [t_i, t_{i+1}]$, $i = 0, 1, \dots, n-1$.
 $g_n(x) = f(t_i) + f[t_i, t_{i+1}](x - t_i)$
 Hence
 $f(x) - g_n(x) = \frac{f''(c_x)}{2} (x - t_i)(x - t_{i+1})$,
 $c_x \in [t_i, t_{i+1}]$
 $\max_{x \in [t_i, t_{i+1}]} |f(x) - g_n(x)| \leq \frac{\|f''\|_\infty h^2}{8}$
 $\Rightarrow \|f - g_n\|_\infty \leq \frac{\|f''\|_\infty h^2}{8} \rightarrow 0 \text{ as } n \rightarrow \infty.$

So, that will be for maximum of modulus of $f(x) - g_1(x)$, where g_1 is our Piecewise Linear Continuous Function for x belonging to t_i to t_{i+1} , but then the bound is going to be independent of I , so the same bound works for each interval t_i to t_{i+1} and we get norm of $f - g_n$ its infinity norm to be less than or equal to norm f'' infinity divided by $8h^2$.

So, it is the bound for the linear polynomial we had applied 2 Piecewise Linear Polynomial on each interval t_i to t_{i+1} .

So, thus we have got the error in the Piecewise Linear Continuous Functions to be less than or equal to constant times h^2 where constant is second derivative norm f'' infinity divided by $8h^2$.

What we are going to do is? Consider an example, look at the function $f(x) = \sqrt{x}$, x belonging to closed interval 1 to 2. So, \sqrt{x} on interval 1 to 2 is going to be infinitely many times differentiable, what we want is? It should be differentiable twice and then we will look at the second derivative, so we can find a value of norm f'' infinity, in this special case $f(x) = \sqrt{x}$, then we will look at this upper bound and suppose, we want the error to be less than 10^{-6} , then we will get our error, which involves $(b-a)^2/n^2$ multiplied by some constant to be less than 10^{-6} and from that we can get the value of n .

So, by looking at the upper bound we can beforehand tell what n we should use, so as to obtain the desired accuracy.

(Refer Slide Time: 24:09)

$f(x) = \sqrt{x}, \quad x \in [1, 2]$
 $\|f - g_n\|_{\infty} \leq \frac{\|f''\|_{\infty} h^2}{8} \quad h = \frac{b-a}{n} = \frac{1}{n}$
 $f'(x) = \frac{1}{2\sqrt{x}}, \quad f''(x) = -\frac{1}{4x^{3/2}}$
 $|f''(x)| = \frac{1}{4x^{3/2}} : \text{decreasing function on } [1, 2]$
 $\max_{x \in [1, 2]} |f''(x)| = \frac{1}{4}$
 $\|f - g_n\|_{\infty} \leq \frac{1}{32} \cdot \frac{1}{n^2} < 10^{-6}$
 provided $n^2 > \frac{10^6}{32} : n = 200$ will work.

The same example we are also going to consider for the Piecewise Quadratic Polynomial, so we have $f(x)$ is equal to root x , x belonging to 1 to 2 we have norm of f minus g_n infinity to be less than or equal to norm f double dash infinity divided by 8 into h square, where h is b minus a by n and in this case it is going to be 1 by n , f dash x is going to be 1 upon 2 root x , f double dash x will be equal to minus 1 by 4 x raise to 3 by 2. When you consider mod of f double dash x , this is going to be 1 upon 4 x raise to 3 by 2, so this is a decreasing function on interval 1 to 2 and hence, maximum of mod of f double dash x , x belonging to 1 to 2, this will be attend at the left end 0.1 and then you get it to be equal to 1 by 4.

So, we have norm of f minus g_n infinity norm to be less than or equal to 1 upon 32 and then 1 upon n square, because h is equal to 1 by n , now this will be less than say 10 raise to minus 6 provided n square is bigger than 10 raise to 6 divided by 32.

So, if you choose n is equal to 200 then that will work, so in fact any number n to be bigger than 200 will work and this is a rough estimate. So, this was about Piecewise Linear Interpolation.

Now we are going to consider Piecewise Quadratic, so first let us look at quadratic polynomials, so 1 single quadratic polynomial defined on interval a, b . For quadratic polynomial interpolation we need 3 points.

So, let us choose those 3 points to be 2 n points of the interval a, b and the midpoint of the interval a, b , because we are choosing the end points and afterwards when we consider the interval a, b subdivide into n equal parts and for each subinterval t_i to t_{i+1} , we will be choosing two end points and the mid-point.

So, because the partition points are going to be the interpolation points for Piecewise Quadratic Function, our resulting function is going to be continuous.

(Refer Slide Time: 27:44)

Handwritten mathematical derivation on a whiteboard:

$$f: [a, b] \rightarrow \mathbb{R}$$

$$p_2(x) = \text{poly. of degree } \leq 2 \text{ such that}$$

$$p_2(a) = f(a), \quad p_2\left(\frac{a+b}{2}\right) = f\left(\frac{a+b}{2}\right),$$

$$p_2(b) = f(b).$$

$$p(x) = f(a) + f\left[\frac{a}{2}, \frac{a+b}{2}\right](x-a) + f\left[\frac{a}{2}, \frac{a+b}{2}, b\right](x-a)\left(x-\frac{a+b}{2}\right) + f\left[\frac{a}{2}, b, x\right](x-a)\left(x-\frac{a+b}{2}\right)(x-b).$$

The last three terms are grouped together with a bracket and labeled $p_2(x)$.

$$f(x) - p_2(x) = \frac{f'''(C_x)}{3!} \omega(x).$$

A small logo for NIPTEL is visible in the bottom left corner of the whiteboard image.

Let me first recall that if f is from a, b to \mathbb{R} , $p_2(x)$ is a polynomial of degree less than or equal to 2, such that p_2 at a is equal to f of a , p_2 at the midpoint a plus b by 2 is f of a plus b by 2 and p_2 b is equal to f of b , then $f(x)$ is going to be equal to f of a plus divided difference based on a, a plus b by 2 into x minus a plus divided difference based on a, a plus b by 2, b, x minus a, x minus a plus b by 2.

So, this is $p_2(x)$ and the error term is going to be f of a, a plus b by 2, b, x and x minus a, x minus a plus b by 2, x minus b , so let me call this as $\omega(x)$, so we have $f(x) - p_2(x)$ is equal to f triple dash at some point C divided by 3 factorial and then $\omega(x)$.

So, when we look at the error, norm of f minus p 2 infinity norm this will be less than or equal to norm f triple dash divided by 3 factorial and into norm of w infinity, so w x is our function x minus a , x minus a plus b by 2, x minus b , we can find the infinity norm for this function, we have got a continuous function when we want to find its maximum. What we have to do is? Look at the value at the n points, look at the value where the derivative vanishes or derivative does not exist.

So, such points they are known as the critical points, so we get hopefully finitely many points, 2 end points and critical points compare the value of the function at this finitely minute points, whichever is the maximum that is going to be absolute maximum of the function, whichever is the minimum it is absolute minimum, you should not go for second derivative test, because the second derivative tells you only about the local maximum or local minimum.

So, let us calculate maximum of mod of w x , x belonging to a, b , so for the sake of convenience we will make a change of variable and then we will calculate.

(Refer Slide Time: 31:36)

The whiteboard shows the following steps:

$$\max_{x \in [a, b]} |w(x)| = \max_{x \in [a, b]} |(x-a)(x-\frac{a+b}{2})(x-b)| = \frac{2}{3\sqrt{3}} \left(\frac{b-a}{2}\right)^3$$

Let $y = x - \frac{a+b}{2}$, $k = \frac{b-a}{2}$. Then $y+k = x-a$, $y-k = x-b$.

$$\max_{y \in [-k, k]} |(y+k)y(y-k)| = \max_{y \in [-k, k]} |y^3 - yk^2|$$

$$3y^2 - k^2 = 0 \Rightarrow y = \pm \frac{k}{\sqrt{3}} \text{ : critical points}$$

$$y = \frac{k}{\sqrt{3}} \quad |y^3 - yk^2| = \left| \frac{k^3}{3\sqrt{3}} - \frac{k^3}{\sqrt{3}} \right| = \frac{2k^3}{3\sqrt{3}}$$

$$y = -\frac{k}{\sqrt{3}} \quad \therefore \text{ same value}$$

So, we have maximum of modulus of w x , x belonging to a, b is equal to maximum of mod of x minus a , x minus a plus b by 2, x minus b , x belonging to a, b , so let y be equal to x minus a plus b by 2 and k to be equal to b minus a by 2. Then when we look at y plus k , that will be nothing but x minus a , y minus k will be x minus b .

And hence, this maximum it reduces to maximum of mod of y minus a or it is going to be maximum of y plus k, y, y minus k, where y is going to vary over, x varies over interval a, b, so x minus a plus b by 2 that is going to vary over minus k to k, since k is b minus a by 2, so we have this is maximum of mod of y cube minus y k square, y belonging to minus k to k. This function vanishes at the 2 end points minus k and k.

Now, let us look at the critical points, so critical point will be given by 3 y square minus k square is equal to 0, this is the derivative value. So, you get y is equal to plus or minus k by root 3, so these are critical points. When you put y is equal to k by root 3 then modulus of y cube minus y k square is going to be k cube by 3 root 3 minus k cube by root 3.

So, this will be 2 k cube divided by 3 root 3 it is modulus and for y is equal to minus k by root 3 you are going to get the same value, so the maximum of this is going to be equal to 2 upon 3 root 3 and k cube is b minus a by 2 whole cube.

So, that is for the norm w infinity and then for the error in the quadratic polynomial we have got norm w infinity and then norm f triple dash infinity divided by 3 factorial.

(Refer Slide Time: 35:24)

$$\|w\|_{\infty} = \max_{x \in [a, b]} \left| (x-a) \left(x - \frac{a+b}{2}\right) (x-b) \right|$$

$$y = x - \frac{a+b}{2}, k = \frac{b-a}{2}$$

$$= \max_{y \in [-k, k]} |(y+k) y (y-k)|$$

$$= \max_{y \in [-k, k]} |y(y^2 - k^2)| = \frac{2k^3}{3\sqrt{3}}$$

Critical point: $3y^2 - k^2 = 0 \Rightarrow y = \pm \frac{k}{\sqrt{3}}$

$$\|f - p_2\|_{\infty} \leq \frac{\|f'''\|_{\infty}}{9\sqrt{3}} \left(\frac{b-a}{2}\right)^3$$

So, this is our norm of f minus p 2 infinity which is less than or equal to norm f triple dash infinity upon 9 root 3 b minus a by 2 cube. So this was for a single polynomial.

(Refer Slide Time: 35:41)

Piecewise Quadratic Polynomial Space

Let

$$X_n = \{f \in C[a, b] : f|_{[t_i, t_{i+1}]} \text{ polynomial of degree } \leq 2\}$$

Then

the dimension of $X_n = 3n - (n-1) = 2n+1$

Let $s_i = \frac{t_i + t_{i+1}}{2}$, $i = 0, 1, \dots, n-1$.

There exists a unique $g_n \in X_n$ such that

$$g_n(t_i) = f(t_i), \quad i = 0, 1, \dots, n, \quad g_n(s_i) = f(s_i)$$

NIPTEL

Now, we consider Piecewise Quadratic, we look at uniform partition x_n is the vector space of functions which are continuous and which are such that on each sub interval it is a polynomial of degree less than or equal to 2.

So, the dimension of the space x_n is going to be n intervals on each interval a polynomial of degree less than or equal to 2 that means 3 coefficients so it is $3n$ and then interior partition points are $n-1$ in number t_1, t_2, \dots, t_{n-1} , you want continuity so subtract $n-1$ and then you get $2n+1$. Now, in order to have a unique g_n belonging to x_n we need to provide $2n+1$ condition, so consider g_n which belongs to x_n , which interpolates the given function at t_i and also at the mid points of the sub interval, such a piece wise polynomial is going to be unique.

Recall that $\max_{x \in [a,b]} |f(x) - p_2(x)| \leq \frac{\|f'''\|_\infty}{9\sqrt{3}} \left(\frac{b-a}{2}\right)^3$.

$\|f'''\|_\infty = \max_{x \in [a,b]} |f'''(x)|$.

Since $t_{i+1} - t_i = h$, $i = 0, 1, \dots, n-1$,

$\max_{x \in [t_i, t_{i+1}]} |f(x) - g_n(x)| \leq \frac{\|f'''\|_\infty}{9\sqrt{3}} \left(\frac{h}{2}\right)^3$ and hence

$\max_{x \in [a,b]} |f(x) - g_n(x)| \leq \frac{\|f'''\|_\infty}{9\sqrt{3}} \left(\frac{h}{2}\right)^3 \rightarrow 0$ as $n \rightarrow \infty$.

And now look at the error, so the error for single polynomial was norm f triple dash infinity upon $9 \text{ root } 3$ b minus a by 2 cube. Look at the interval t_i to t_{i+1} , so replace the interval a, b by t_i to t_{i+1} , then upper bound is norm f triple dash infinity by $9 \text{ root } 3$ into h by 2 cube, we could have taken maximum for the third derivative only on the interval t_i to t_{i+1} . Still it could have provided us an upper bound but we wanted upper bound which is independent of I , so for each interval t_i to t_{i+1} we have got the same bound, so if you take maximum over the whole interval a, b , it is going to be the same bound and notice that here the error is less than or equal to constant times h cube.

The constant will involve the third derivative of the function and then the constants $9 \text{ root } 3$ and then it in the denominator. We look at again the same function $f(x)$ is equal to $\text{root } x$, for this $\text{root } x$ for Piecewise Linear Continuous Approximation we saw that the in order to have the error to be less than 10^{-6} we have to choose n to be about 200.

Now, here because our error is less than or equal to constant times h cube definitely the constant here and a constant in Piecewise Linear these two constants they are different. For Piecewise Linear Approximation the constant was depending on the second derivative, now here it is depending on third derivative, so here for piece wise quadratic the convergence proved under the condition that f is 3 times differentiable.

So, now we have constant times h cube and then we hope that the accuracy 10^{-6} should be achieved for a smaller value of n , because h cube converges faster to 0 than h square, and this turns out to be the case.

$f(x) = \sqrt{x}, x \in [1, 2]. \|f - g_n\|_{\infty} \leq \frac{\|f'''\|_{\infty}}{72\sqrt{3}} h^3$
 $f'(x) = \frac{1}{2\sqrt{x}}, f''(x) = -\frac{1}{4x^{3/2}}, f'''(x) = \frac{3}{8x^{5/2}}.$
 $\|f'''\|_{\infty} = \frac{3}{8}, \|f - g_n\|_{\infty} \leq \frac{1}{192\sqrt{3}} \left(\frac{1}{n}\right)^3$
 $\|f - g_n\|_{\infty} < 10^{-6} \text{ if } n^3 > \frac{10^6}{192\sqrt{3}}$
 $n = 20 \text{ will work.}$

And when you do a bit of computation we had calculated up to f'' , now we have to calculate f''' , so that is going to be 3 by 8 x raise to 5 by 2 .

Once again 1 upon x raise to 5 by 2 is a decreasing function on closed interval 1 to 2 and hence, the maximum will be attained at the left hand point which is 1 and hence, norm of f''' infinity is equal to 3 by 8 .

Then we get norm of $f - g_n$ infinity which is less than or equal to a constant into 1 by n cube, so this upper bound will be less than 10^{-6} provided n cube is bigger than 10^6 divided by 192 into root 3 . So in this case n is equal to 20 will work, the values of n is equal to 200 and n is equal to 20 these are rough estimates, you can try to find the better estimate.

So, far we had considered Piecewise Interpolation where you were interpolating the function, now we are going to consider Piecewise Cubic Polynomial which interpolates function values and the derivative values at the partition points.

So, here the interpolation which we are going to explain, it can be done provided your derivative values of the function they are also available. This may not be always the case if only function values are available then we cannot do this Piecewise Cubic Hermite Interpolation.

Now, the method or the methodology is the same, consider the cubic hermite interpolation and then do that for each subinterval. We have already seen cubic polynomial interpolation, which interpolates the given function at two end points a and b and its derivative values at a and b.

In order to determine a cubic polynomial, since there are 4 coefficients to be determined we need 4 interpolation condition, these 4 interpolation conditions can be either 4 distinct interpolation points or 4 points which can be repeated.

(Refer Slide Time: 40:06)

$$f(x) = \sqrt{x}, \quad x \in [1, 2]. \quad \|f - g_n\|_\infty \leq \frac{\|f'''\|_\infty}{72\sqrt{3}} h^3$$

$$f'(x) = \frac{1}{2\sqrt{x}}, \quad f''(x) = -\frac{1}{4x^{3/2}}, \quad f'''(x) = \frac{3}{8x^{5/2}}$$

$$\|f'''\|_\infty = \frac{3}{8}, \quad \|f - g_n\|_\infty \leq \frac{1}{192\sqrt{3}} \left(\frac{1}{n}\right)^3$$

$$\|f - g_n\|_\infty < 10^{-6} \quad \text{if} \quad n^3 > \frac{10^6}{192\sqrt{3}}$$

$$n = 20 \quad \text{will work.}$$

So, we are repeating the left hand point a twice and right hand point b twice. In this case we had seen, that the error involves the divided difference based on a repeated twice b repeated twice x and multiplied by function w x which is x minus a, into x minus b whole square.

Already we had seen that maximum of modulus of x minus a, x minus b, it is attend at the midpoint a plus b by 2, so for the square x minus a square x minus b square again the

maximum is going to be attained at $a + \frac{b}{2}$ and that gives us an upper bound for the cubic Hermite interpolation.

This result for a single cubic Hermite interpolation we will apply for each interval and then obtain a Piecewise Cubic function which is not only continuous, but it is differentiable.

If we had decided to choose four distinct points in each interval, like for linear we had chosen two points to be end points, for quadratic we had chosen three points which involve two end points and a midpoint, so similarly for the Piecewise Cubic Interpolation we could have chosen two end points and two other points in the interior of the interval.

So we get four distinct points, if you do that then because we are choosing the interpolation points, our interpolation points include the partition points the function will be continuous.

But, then for the Cubic Hermite Interpolation by virtue of the fact that you are interpolating the given function and its derivative at the two end points our function is going to be continuously differentiable function.

So, you get continuously differentiable function, you are going to get the error to be less than or equal to constant times h^4 , the drawback is you may not know the derivative values at the points t_i .

So, what I will like to have is have a Piecewise Cubic Polynomial, then because it is cubic, I can ask for overall continuity to be C^2 continuity that means the function is continuous, the derivative is continuous and second derivative is continuous, so still I retain the Piecewise structure and then we will also like to have the order of convergence to be h^4 .

So that is the Cubic Spline Interpolation, so we will be considering that and so far we could write down explicit formula for the polynomials in terms of the function values for cubic spline we will have to solve a system of equations.

So, Piecewise Cubic Hermite Interpolation and Cubic Spline Interpolation are going to be the topic of our next lecture thank you.
