**Cubic Spline Interpolation**

In our last lecture, we considered Piecewise Linear and Piecewise Quadratic Approximation. Today, we are going to consider Piecewise Cubic Polynomial Approximation, so first we will consider Piecewise Cubic Hermite Interpolation, in that our approximating function is going to be continuously differentiable, and we will interpolate the given function and its derivative values, at the partition points of our interval  $a$  to  $b$ .

Next, we will consider Cubic Spline Interpolation, Cubic Spline is going to be a Piecewise Cubic Polynomial which is overall  $C^2$ , that means it is 2 times continuously differentiable and it will interpolate the given function  $f$  its values at the partition point.

In the case of Piecewise Cubic Hermite Interpolation we will show that the error is going to be less than or equal to constant times  $h^4$ , where  $h$  is length of the sub interval, which is  $(b-a)/n$  if we are dividing our interval  $a$  to  $b$  into  $n$  equal parts.

In case of Cubic Spline Interpolation, the error is going to be less than or equal to constant times  $h^4$  or constant times  $h^2$ , depending upon the end conditions which we imports. In the case of cubic spline interpolation, it will be necessary to add to the  $n+1$  interpolation conditions, 2 more extra conditions which will make our cubic spline a unique function.

For the cubic hermite polynomial, the construction is going to be straight forward and the error analysis also is straight forward, it will be like in the case of Piecewise Linear and Piecewise Quadratic Polynomial, the drawback in Piecewise Cubic Hermite Interpolation is we need to know the derivative values of the function at the partition points which may not be available, that is why one goes to Cubic Spline Interpolation.

(Refer Slide Time: 03:23)

$f: [a, b] \rightarrow \mathbb{R}$ , differentiable.  
 $p_3$ : poly. of degree  $\leq 3$  such that  
 $p_3(a) = f(a)$ ,  $p_3(b) = f(b)$   
 $p_3'(a) = f'(a)$ ,  $p_3'(b) = f'(b)$   
 $p_3(x) = f(a) + (x-a)f'(a) + f[a, a, b](x-a)^2$   
 $+ f[a, a, b, b](x-a)^2(x-b)$ .  
 $f(x) - p_3(x) = f[a, a, b, b, x](x-a)^2(x-b)^2$ ,  
 $x \in [a, b]$ .  
 $f$  is 4-times differentiable  $= \frac{f^{(4)}(c_x)}{4!} (x-a)^2(x-b)^2$

Let, me recall Cubic Hermite Interpolation, so when we have a function  $f$  defined on interval  $a$   $b$  to real line, look at  $p_3$  to be a polynomial of degree less than or equal to 3, such that  $p_3$  at  $a$  is equal to  $f$  of  $a$ ,  $p_3$  at  $b$  is equal to  $f$  of  $b$  and  $p_3$  dash at  $a$  is equal to  $f$  dash  $a$ ,  $p_3$  dash  $b$  is equal to  $f$  dash  $b$ , where dash denotes the derivative.

So, that means we need to assume the function  $f$  to be differentiable, we have seen that  $p_3(x)$  can be written in terms of divided differences as  $f$  of  $a$  plus  $x$  minus  $a$ ,  $f$  dash  $a$  plus divided difference based on  $a$   $a$   $b$ , the point  $a$  is repeated twice multiplied by  $x$  minus  $a$  square and plus the divided difference based on 4 points  $a$   $a$   $b$   $b$ ,  $a$  repeated twice  $b$  repeated twice  $x$  minus  $a$  square,  $x$  minus  $b$  square, the error  $f(x) - p_3(x)$  is given by  $f$  of  $a$   $b$   $x$  multiplied by  $x$  minus  $a$  square,  $x$  minus  $b$  square for  $x$  in the interval  $a$  to  $b$ , so this is the error.

Now, if  $f$  is 4 times differentiable then we can write the divided difference as fourth derivative of  $f$  evaluated at some point  $c$ ,  $c$  is going to depend on  $x$  divided by 4 factorial  $x$  minus  $a$  square,  $x$  minus  $b$  square.

(Refer Slide Time: 05:59)

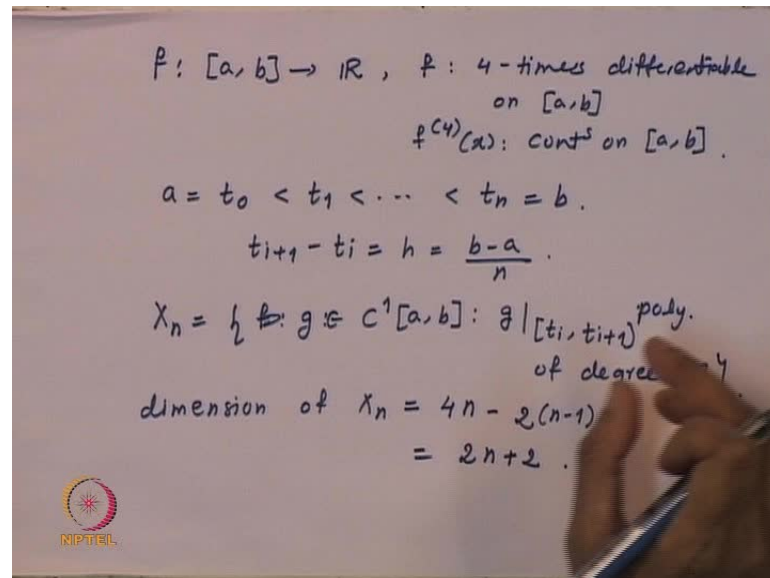

$$\max_{x \in [a, b]} |f(x) - p_3(x)| \leq \max_{x \in [a, b]} \frac{|f^{(4)}(x)|}{4!} \max_{x \in [a, b]} |(x-a)(x-b)|^2$$
$$\|f - p_3\|_{\infty} \leq \frac{\|f^{(4)}\|_{\infty}}{4!} \left(\frac{b-a}{2}\right)^4$$

Now, we look at the maximum error, so maximum of modulus of  $f(x) - p_3(x)$ ,  $x$  belonging to  $a$  to  $b$  to be less than or equal to maximum of modulus of  $f^{(4)}(x)$  divided by  $4!$  multiplied by maximum of modulus of  $(x-a)(x-b)^2$ ,  $x$  belonging to  $a$  to  $b$ .

Thus, norm of  $f - p_3$  infinity norm is going to be less than or equal to norm of  $f^{(4)}$  infinity norm divided by  $4!$  and the maximum is going to be attained at the midpoint  $a + \frac{b-a}{2}$ , so that will give us  $(\frac{b-a}{2})^4$ .

So, thus we have obtained the upper bound for the cubic Hermite interpolating polynomial, this upper bound we are going to use for finding an upper bound for the error in the Piecewise Cubic Hermite Interpolation.

(Refer Slide Time: 07:59)

So, it is this bound is applicable on interval a b, so the same bound we will use with interval a b replaced by interval t i to t i plus 1, where i going from 1 to up to n minus 1 and that will give us the an upper bound for the error in the Piecewise Cubic Hermite Interpolation, f defined on interval a b taking real values the differentiability property of f which we are going to need is, f should be 4 times differentiable on a b and the fourth derivative should be continuous on interval a b, because we are going to take the maximum of mod of f4 x for x belonging to a b.

We look at uniform partition a is equal to t 0 less than t 1 less than t n is equal to b, t i plus 1 minus t i which is length of the sub interval which is equal to h, that is b minus a by n. Let us, look at x n to be set of all f or let me write g, set of all g belonging to c 1 a b, so the all functions which are continuously differentiable, such that g restricted to t i to t i plus 1 is a polynomial of degree less than or equal to 3, then the dimension of x n is equal to we had done such calculation before, on each interval it is a polynomial of degree 3 degree less than or equal to 3 so we have got 4 degrees of freedom, there are n intervals, so it will be 4 n minus, there are n minus 1 interior nodes t 1 t 2 t n minus 1.

We want the function to be continuously differentiable that means at each of the interior node we are putting 2 constraints, so then those 2 constraints they will decrease the dimension of our spline, so it will be 4 n minus 2 into n minus 1, so that is going to be equal to 2 n plus 2, so we have dimension of x n to be equal to 2 n plus 2. If we consider

a value of function  $f$  at  $t_i$ 's and the derivative values at  $t_i$ , we have got  $n$  plus 1 partition points and if we say that, look at a function  $g$  which is going to be continuously differentiable and which is Piecewise Cubic on the interval  $t_i$  to  $t_{i+1}$  and it interpolates our function  $f$  and derivative at this  $n$  plus 1 points.

(Refer Slide Time: 11:26)

So, dimension of our space is  $2n + 2$ , we are putting  $2n + 1$  condition,  $2n + 2$  conditions and then such a function is going to be unique. We have  $f$  is from  $a$  to  $b$  to  $\mathbb{R}$  and  $g_n$  should belong  $X_n$ , such that  $g_n$  at  $t_i$  is equal to  $f$  at  $t_i$  and  $g_n$  dash at  $t_i$  should be equal to  $f$  dash at  $t_i$ ,  $i$  going from  $0$  to  $n$ , so we have this is our partition and we are specifying at all the partition points value of  $g_n$  at  $t_i$  and value of  $g_n$  dash at  $t_i$ .

So, by vary construction our  $g_n$  is going to be belonging to  $X_n$  and  $g_n$  will be given by on the interval  $t_i$  to  $t_{i+1}$ , because it is a cubic polynomial it is  $g_n$  at  $t_i$  plus  $g_n$  dash at  $t_i$  into  $x$  minus  $t_i$  plus  $g_n$  divided difference based on 3 points  $t_i, t_i, t_{i+1}$  the divided difference into  $x$  minus  $t_i$  square plus divided difference based on 4 points  $t_i, t_i, t_{i+1}, t_{i+1}$ ,  $x$  minus  $t_i$  square  $x$  minus  $t_{i+1}$ .

(Refer Slide Time: 13:26)

$$\|f - p_3\|_\infty \leq \frac{\|f^{(4)}\|_\infty}{4!} \left(\frac{b-a}{2}\right)^4.$$

$$\max_{x \in [t_i, t_{i+1}]} |f(x) - g_n(x)| \leq \frac{\max_{x \in [t_i, t_{i+1}]} |f^{(4)}(x)|}{4!} \left(\frac{h}{2}\right)^4.$$

$$\leq \frac{\|f^{(4)}\|_\infty}{4!} \left(\frac{h}{2}\right)^4.$$

$$\max_{x \in [a, b]} |f(x) - g_n(x)| = \max_{0 \leq i \leq n-1} \max_{x \in [t_i, t_{i+1}]} |f(x) - g_n(x)|$$

$$\|f - g_n\|_\infty \leq \frac{\|f^{(4)}\|_\infty}{4!} \left(\frac{h}{2}\right)^4.$$

Piecewise cubic hermite interpolation.

So, exactly similar formula as on the interval  $a, b$  only now the interval is  $t_i$  to  $t_{i+1}$ . We had found the bound for the interval  $a, b$  and that bound was norm of  $f$  minus  $p_3$  infinity norm to be less than or equal to norm  $f^{(4)}$  infinity divided by 4 factorial  $b$  minus  $a$  by 2 raise to 4 and hence, maximum of mod of  $f(x) - g_n(x)$ ,  $x$  in the interval  $t_i$  to  $t_{i+1}$ , this will be less than equal to maximum of mod of  $f^{(4)}(x)$ ,  $x$  belonging to  $t_i$  to  $t_{i+1}$  divided by 4 factorial and then we have to replace  $b$  minus  $a$  by  $h$ , so we are going to have  $h$  by 2 raise to 4.

Now, this will be less than or equal to norm  $f^{(4)}$  infinity divided by 4 factorial  $h$  by 2 raise to 4, the bound which I am writing now that is true for each  $i$  and hence, when we look at maximum of mod of  $f(x) - g_n(x)$ ,  $x$  belonging to  $a, b$  this is going to be equal to maximum over  $i$  maximum of mod of  $f(x) - g_n(x)$ ,  $x$  belonging to  $t_i$  to  $t_{i+1}$ ,  $0 \leq i \leq n-1$ , which will be less than or equal to norm  $f^{(4)}$  infinity by 4 factorial  $h$  by 2 raise 4 and this is norm  $f - g_n$  infinity this is the error for Piecewise Cubic Hermite Interpolation.

(Refer Slide Time: 15:53)

Piecewise Linear (Continuous)

$$\max_{x \in [a, b]} |f(x) - g_n(x)| \leq \frac{\|f''\|_{\infty} h^2}{8} \rightarrow 0 \text{ as } n \rightarrow \infty$$

Piecewise Quadratic (Continuous)

$$\max_{x \in [a, b]} |f(x) - g_n(x)| \leq \frac{\|f'''\|_{\infty} h^3}{72\sqrt{3}} \rightarrow 0 \text{ as } n \rightarrow \infty$$

Piecewise Cubic (Continuously Differentiable)

$$\max_{x \in [a, b]} |f(x) - g_n(x)| \leq \frac{\|f^{(4)}\|_{\infty} h^4}{384} \rightarrow 0 \text{ as } n \rightarrow \infty$$

$f'(t_i) : i = 0, 1, \dots, n$  may not be known.

Let us, recall the bounds for Piecewise Linear and Piecewise Quadratic, so in case of piecewise linear, our function was continuous and the error it was less than or equal to constant times  $h$  square where the constant involved the second derivative, in case of piecewise quadratic again the function is continuous and the error now is less than or equal to norm  $f$  triple dash infinity that means the third derivative is coming into picture divided by  $92\sqrt{3}$  into  $h$  cube and now for Piecewise Cubic Hermite Interpolation our function is continuously differentiable and the error is less than or equal to constant times  $h$  raise to 4.

So, the constants in the 3 cases they are going to be different but these are the constants which are independent of  $h$ , so in case of cube Piecewise Cubic Hermite Interpolation we have got the error to be constant times  $h$  raise to 4 which will tend to 0 faster than in the case of Piecewise Linear and Piecewise Quadratic Polynomials and in addition our function is continuously differentiable. The approximating function is continuously differentiable, the only problem is the derivative of  $f$  at  $t_i$ 's they may not be known.

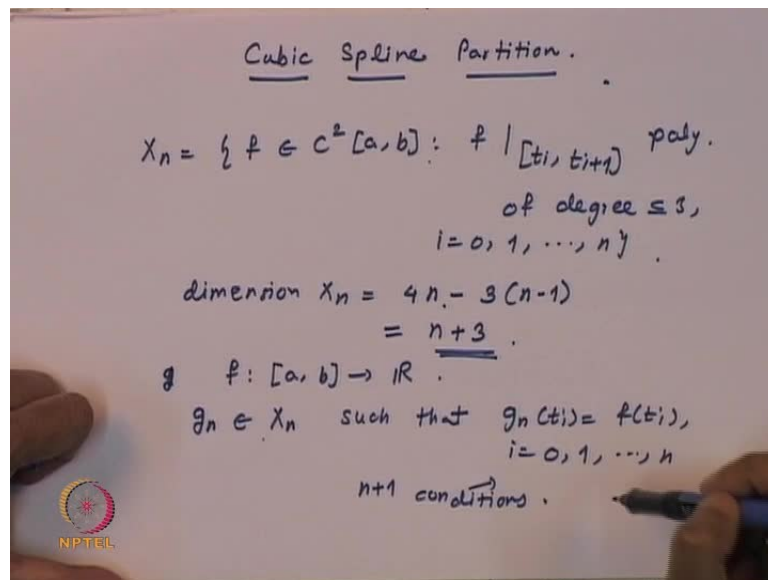

Next we go to cubic spline interpolation, we want our approximating function to depend only on the function values at the partition points and if possible we will like to make our function to be 2 times differentiable. When we looked at joining of 2 polynomials together we have seen that if you join 2 cubic polynomials together in  $C^2$  fashion still we retain the piecewise nature of our function on the other hand, if we say that there are

2 cubic polynomials and you join them together, such that the function value derivative value second derivative and third derivative values they should match then it has to be a single polynomial.

So, the best we can do by still retaining the Piecewise nature is a Piecewise Cubic Polynomial which is 2 times continuously differentiable, now here the construction of such a function is going to be little more complicated.

So, far we could write we could look at the divided differences and then we could write down the explicitly our Approximating Polynomial or Approximating Piecewise Polynomial.

(Refer Slide Time: 19:07)

Now, here in case of cubic specific line interpolation, so look at as before the uniform partition and look at the space  $x_n$  to be set of all  $f$  belonging to  $c^2$   $a$   $b$  such that  $f$  restricted to  $t_i$  to  $t_{i+1}$  is a polynomial of degree less than or equal to 3,  $i$  is equal to 0 1 up to  $n$ , dimension of  $x_n$  is going to be 4 times  $n$  minus 3 times  $n$  minus 1,  $n$  intervals on each interval a polynomial of degree less than or equal 3, so that is why 4  $n$  degrees of liberty and then at the interior partition points  $t_1$   $t_2$   $t_{n-1}$ , we want the function to be 2 times differentiable, so that is why you have got minus 3 into  $n$  minus 1, so then that is going to be equal to  $n$  plus 3. Suppose, our function  $f$  is defined on interval  $a$   $b$  to real line and look at  $g_n$  belonging to  $x_n$  such that  $g_n$  at  $t_i$  is equal to  $f$  at  $t_i$ ,  $i$  is equal to 0 1 up to  $n$ , so these are  $n$  plus 1 conditions.

The dimension of the space is  $n + 3$ , so in order to have such a unique interpolating function we will need to add 2 conditions, now these 2 conditions generally they are put at the 2 end points and those are the end conditions.

So, we will come to the end conditions little later, let us look at the construction of  $g_n$ , on the interval  $t_i$  to  $t_{i+1}$ ,  $g_n$  is going to be a polynomial of degree less than or equal to 3, so suppose you have got  $g_n$  at  $t_i$  and  $g_n$  at  $t_{i+1}$  they are already fixed they are equal to  $f$  is our function which is given to us so  $g_n$  at  $t_i$  is equal to  $f$  at  $t_i$   $g_n$  at  $t_{i+1}$  is equal to  $f$  at  $t_{i+1}$ , treat the derivative values  $g_n$  dash at  $t_i$  and  $g_n$  dash at  $t_{i+1}$  as unknowns and use a fact that our  $g_n$  is going to be 2 times differentiable to get a relation which will be satisfied by  $g_n$  dash  $t_i$ , so the unknowns  $g_n$  dash  $t_i$  they will be obtained by solving a linear system of equations.

(Refer Slide Time: 23:02)

$P_i''(t_{i+}) = P_{i-1}''(t_{i-})$ .

$\begin{array}{ccccccc} & & \leftarrow & & \rightarrow & & \\ & & \text{---} & & \text{---} & & \\ t_{i-1} & \uparrow & & t_i & \uparrow & & t_{i+1} \end{array}$

$P_{i-1} = g_n |_{[t_{i-1}, t_i]}$        $P_i = g_n |_{[t_i, t_{i+1}]}$

$$P_i(x) = g_n(t_i) + g_n'(t_i)(x - t_i) + g_n[t_i, t_i, t_{i+1}](x - t_i)^2 + g_n[t_i, t_i, t_{i+1}, t_{i+1}](x - t_i)^2(x - t_{i+1})$$

$P_i''(x), \quad P_i''(t_{i+}), \quad P_i''(t_{i+1-})$   
 $\downarrow$   
 $P_{i-1}''(t_{i-+}), \quad P_{i-1}''(t_{i-})$

And then once you get  $g_n$  dash  $t_i$  on the interval  $t_i$  to  $t_{i+1}$  our polynomial of degree less than or equal to 3 will be determined, because we know  $g_n$  at  $t_i$   $g_n$  dash  $t_i$   $g_n$  at  $t_{i+1}$   $g_n$  dash at  $t_{i+1}$ , so let me explain how we are going to get the relation, so let us look at 2 intervals, so this is our interval  $t_i$  to  $t_{i+1}$  and this is interval  $t_{i-1}$  to  $t_i$ . Here, let me denote the polynomial by  $p_i$ , so that is  $g_n$  restricted to  $t_i$  to  $t_{i+1}$  the polynomial here we denote it by  $p_{i-1}$ , so it is going to be  $g_n$  restricted to  $t_{i-1}$  to  $t_i$ .

The polynomial  $p_i$  we are going to write in terms of the value of  $g_n$  at  $t_i$  and value of  $g_n$  dash at  $t_{i+1}$ , so at present the derivatives are unknown, so we have got  $p_i(x)$  to be equal to the same cubic hermite polynomial  $g_n$  at  $t_i$  plus  $g_n$  dash at  $t_{i+1}$  into  $x$  minus  $t_i$  plus divided difference based on  $t_i, t_i, t_i + 1, x$  minus  $t_i$  square plus  $g_n$  at  $t_i, t_i, t_i + 1, t_i + 1, x$  minus  $t_i$  square,  $x$  minus  $t_i + 1$ .

So, how is it different from the cubic hermite interpolation. In case of cubic hermite interpolation we wrote exactly the same formula but  $g_n$  dash at  $t_{i+1}$  was given to us,  $g_n$  dash at  $t_i$  was equal to  $f$  at  $t_i$ .

Now, in our case  $g_n$  at  $t_i$  is going to be equal to  $f$  at  $t_i$  that is given to us but at present  $g_n$  dash at  $t_i$  they are going to be unknown, so this is we have found or we have written down a formula for the cubic polynomial in the interval  $t_i$  to  $t_i + 1$  in terms of  $g_n$  at  $t_i, g_n$  dash at  $t_{i+1}$  of which  $g_n$  dash at  $t_i$  are unknown. Now, you look at the second derivative, so we can calculate  $p_i$  double dash  $x$ , you calculate the second derivative and then you look at  $p_i$  double dash of  $t_i + 1$  and  $p_i$  double dash at  $t_i + 1$  minus, we have got a formula for  $p_i(x)$  take its second derivative, the second derivative will be in terms of again  $g_n$  at  $t_i$  and  $g_n$  dash at  $t_{i+1}$ , I have written  $p_i$  double dash  $t_i + 1$ , because our  $p_i$  is defined on the interval  $t_i$  to  $t_i + 1$ .

So, the second derivative is at  $t_i$  is going to be the right handed derivative and at  $t_i + 1$  it is going to be left handed derivative so we calculate these values, then from here we write  $p_i$  minus 1 double dash  $t_i - 1$  plus and  $p_i$  minus 1 double dash  $t_i - 1$  minus, so once we obtain the formulae for this you have to just shift replace  $i$  by  $i - 1$  in order to get this expression, now this continuity of second derivative comes into picture. What we want is? We want  $p_i$  double dash at  $t_i + 1$  is equal to  $p_{i-1}$  double dash of  $t_i$  minus the value of the second derivative from the right and the value of the second derivative from the left, we equate these 2 and that is going to give us a relation which the derivatives they should satisfy.

(Refer Slide Time: 28:10)

$a = t_0 \quad t_1 \quad t_2 \quad \dots \quad t_{n-1} \quad t_n = b$   
 $g_n \in C^2[a, b]$ ,  $g_n$ : piecewise cubic  
 $g_n(t_i) = f(t_i)$ ,  $i = 0, 1, \dots, n$ .  
 $g_n$  is completely determined if we know  
 $g_n'(t_i)$ ,  $i = 0, 1, \dots, n$ .  
 For  $x \in [t_i, t_{i+1}]$ :  
 $g_n(x) = g_n(t_i) + g_n'(t_i)(x - t_i) + g_n[t_i, t_i, t_{i+1}](x - t_i)^2$   
 $+ g_n[t_i, t_i, t_{i+1}, t_{i+1}](x - t_i)^2(x - t_{i+1})$

(Refer Slide Time: 28:34)

$t_{i-1} \quad t_i \quad t_{i+1}$   
 $P_{i-1} \quad P_i$   
 Let  $g_n|_{[t_i, t_{i+1}]} = P_i$ ,  $g_n|_{[t_{i-1}, t_i]} = P_{i-1}$ .  
 $g_n \in C^2[a, b]$  if  $P_i''(t_{i+1}) = P_{i-1}''(t_i)$ .  
 $P_i(x) = g_n(t_i) + g_n'(t_i)(x - t_i) + g_n[t_i, t_i, t_{i+1}](x - t_i)^2$   
 $+ g_n[t_i, t_i, t_{i+1}, t_{i+1}](x - t_i)^2(x - t_{i+1})$   
 $P_i'(x) = g_n'(t_i) + g_n[t_i, t_i, t_{i+1}] \cdot 2(x - t_i)$   
 $+ g_n[t_i, t_i, t_{i+1}, t_{i+1}] \{ 2(x - t_i)(x - t_{i+1}) + (x - t_i)^2 \}$

So, now what comes is the technical thing like I have explained to you what is the idea and now let us work out the details look at the interval  $t_i$  to  $t_{i+1}$  and then we have written  $g_n(x)$  in terms of  $g_n(t_i)$ ,  $g_n'(t_i)$  and then the divided differences, these divided differences they also will be in terms of the  $g_n$  value of  $g_n$  at  $t_i$  and value of  $g_n'$  at  $t_i$ . Now, look at the derivative, so when you take the derivative you get  $g_n'$  at  $t_i$  the  $g_n$  at  $t_i$  is constant so the derivative term vanishes, then we have  $g_n'$  at  $t_i$  plus the divided difference based on  $t_i, t_i, t_{i+1}$  the derivative of  $(x - t_i)^2$  which will be  $2(x - t_i)$  plus the divided difference based on  $t_i, t_i, t_{i+1}, t_{i+1}$  the derivative of  $(x - t_i)^2(x - t_{i+1})$  which will be  $2(x - t_i)(x - t_{i+1}) + (x - t_i)^2$  and then the derivative of  $(x - t_i)^2$ ,  $(x - t_{i+1})$  that is going to be

2 times  $x$  minus  $t_i$ ,  $x$  minus  $t_i$  plus 1 plus  $x$  minus  $t_i$  square, so we have found the first derivative.

(Refer Slide Time: 29:33)

The slide shows the following mathematical derivation:

$$P_i'(x) = g_n'(t_i) + g_n[t_i, t_i, t_{i+1}] \cdot 2(x - t_i) + g_n[t_i, t_i, t_{i+1}, t_{i+1}] \{ 2(x - t_i)(x - t_{i+1}) + (x - t_i)^2 \}$$

$$\Rightarrow P_i''(x) = 2g_n[t_i, t_i, t_{i+1}] + g_n[t_i, t_i, t_{i+1}, t_{i+1}] \{ 4(x - t_i) + 2(x - t_{i+1}) \}$$

$$P_i''(t_{i+}) = 2g_n[t_i, t_i, t_{i+1}] - 2h g_n[t_i, t_i, t_{i+1}, t_{i+1}]$$

$$P_i''(t_{i+1}-) = 2g_n[t_i, t_i, t_{i+1}] + 4h g_n[t_i, t_i, t_{i+1}, t_{i+1}]$$

$$P_{i-1}''(t_i-) = 2g_n[t_{i-1}, t_{i-1}, t_i] + 4h g_n[t_{i-1}, t_{i-1}, t_i, t_i]$$

Equate  $P_i''(t_{i+}) = P_{i-1}''(t_i-)$

Now, you differentiate once more to get the second derivative, so when you look at the second derivative  $g_n$  dash at  $t_i$  being constant, its derivative will be 0, derivative of  $x$  minus  $t_i$  will be 1, so that gives us term 2 times divided difference based on  $t_i, t_i, t_i$  plus 1 plus divided difference based on  $t_i, t_i, t_i$  plus 1 and then the derivative.

So, we are going to have 4 times  $x$  minus  $t_i$  plus 2 times  $x$  minus  $t_i$  plus 1, so this is expression for the second derivative of  $p_i$  on the interval  $t_i$  to  $t_i$  plus 1 and  $p_i$  is nothing, but restriction of  $g_n$  to the interval  $t_i$  to  $t_i$  plus 1, the value of  $p_i$  double dash at  $t_i$  from the right that is given by putting  $x$  is equal to  $t_i$ .

So, when you do that you get the expression on the right, the term  $x$  minus  $t_i$  vanishes,  $x$  minus  $t_i$  plus 1, so that is  $t_i$  minus  $t_i$  plus 1 that gives us minus  $h$ .

Next, you put  $x$  is equal to  $t_i$  plus 1 in the expression then you get 2 times  $g_n$   $t_i, t_i, t_i$  plus 1 the divided difference plus 4  $h$  times divided difference based on  $t_i, t_i, t_i$  plus 1  $t_i$  plus 1. We want to equate  $p_i$  double dash at  $t_i$  plus and  $p_i$  minus 1 double dash at  $t_i$  minus, so in the expression for  $p_i$  double dash at  $t_i$  plus 1 minus replace  $i$  by  $i$  minus 1, so you get it to be equal to 2 times  $g_n$  divided difference based on now  $t_i$  minus 1  $t_i$  minus 1  $t_i$  plus 4  $h$  times divided difference based on  $t_i$  minus 1 and  $t_i$  repeated twice

(Refer Slide Time: 31:53)

$$\begin{aligned}
 P_i''(t_{i+}) &= 2g_n[t_i, t_i, t_{i+1}] - 2hg_n[t_i, t_i, t_{i+1}, t_{i+1}] \\
 &= 4g_n[t_i, t_i, t_{i+1}] - 2g_n[t_i, t_{i+1}, t_{i+1}] \\
 &= \frac{4}{h} \{g_n[t_i, t_{i+1}] - g_n'(t_i)\} - \frac{2}{h} \{g_n'(t_{i+1}) - g_n[t_i, t_{i+1}]\} \\
 &= \frac{6g_n[t_i, t_{i+1}] - 4g_n'(t_i) - 2g_n'(t_{i+1})}{h} \\
 P_{i-1}''(t_{i-}) &= 2g_n[t_{i-1}, t_{i-1}, t_i] + 4hg_n[t_{i-1}, t_{i-1}, t_i, t_i] \\
 &= -2g_n[t_{i-1}, t_{i-1}, t_i] + 4g_n[t_{i-1}, t_i, t_i] \\
 &= \frac{-6g_n[t_{i-1}, t_i] + 4g_n'(t_i) + 2g_n'(t_{i-1})}{h}
 \end{aligned}$$

And now we will do the simplifications, so look at  $P_i''$  at  $t_i$  plus use the recurrence relation for the divided differences, so the divided difference  $g_n[t_i, t_i, t_{i+1}]$  will be  $g_n[t_i, t_{i+1}] - g_n'(t_i)$  divided by  $t_{i+1} - t_i$  which is going to be equal to  $h$ .

Then, similarly use the recurrence relation for the divided difference based on  $t_i$  and  $t_{i+1}$  repeated twice do the simplifications and you get the second derivative to be  $6$  times divided difference based on  $t_i, t_{i+1}$  minus  $4$  times  $g_n'(t_i)$  minus  $2$  times  $g_n'(t_{i+1})$  divided by  $h$ .

The simplification of  $P_{i-1}''$  at  $t_i$  minus gives us  $-6$  times  $g_n[t_{i-1}, t_i]$  plus  $4$  times  $g_n'(t_i)$  plus  $2$  times  $g_n'(t_{i-1})$  divided by  $h$ .

Look at the expression  $6$  times  $g_n[t_i, t_{i+1}]$  in  $P_i''$ , so that divided difference is going to be  $g_n[t_i, t_{i+1}] - g_n'(t_i)$  divided by  $h$  and we know that  $g_n[t_i, t_{i+1}]$  has to be equal to  $f(t_{i+1}) - f(t_i)$ , so that is known.

Whereas,  $g_n'(t_i)$  minus  $g_n'(t_{i+1})$  these are unknowns, so we will equate these 2 expressions, on the left hand side we will leave the unknowns which involve the derivatives of  $g_n$  and on the right hand side we will have the function values of  $g_n$  at  $t_i$  which are known.

(Refer Slide Time: 33:51)

$$P_i''(t_{i+}) = \frac{6g_n[t_i, t_{i+1}] - 4g_n'(t_i) - 2g_n'(t_{i+1})}{h}$$

$$P_{i-1}''(t_{i-}) = \frac{-6g_n[t_{i-1}, t_i] + 4g_n'(t_i) + 2g_n'(t_{i-1})}{h}$$

$$\Rightarrow g_n'(t_{i-1}) + 4g_n'(t_i) + g_n'(t_{i+1}) = 3 \left\{ \frac{g_n[t_i, t_{i+1}] + g_n[t_{i-1}, t_i]}{h} \right\}$$

$$= 3 \frac{g_n(t_{i+1}) - g_n(t_{i-1})}{h} = \beta_i,$$

$i = 1, 2, \dots, n-1$

$g_n'(t_i) : n+1$  unknowns

$g_n(t_i) = f(t_i), i = 0, 1, \dots, n : \text{Given}$

And thus, equating we get the system to be  $g_n'(t_{i-1}) + 4g_n'(t_i) + g_n'(t_{i+1}) = 3 \frac{g_n(t_{i+1}) - g_n(t_{i-1})}{h}$  plus 1 minus  $g_n(t_{i-1})$  divided by  $h$  and which we denote by  $\beta_i$ . Here  $i$  is going to vary from 1 2 up to  $n-1$ , because the equating the second derivatives that we need to do only at the interior node points.

(Refer Slide Time: 34:37)

This was our uniform partition  $t_0, t_1, t_2, \dots, t_{n-1}, t_n$ , we want  $g_n$  to be in  $C^2[a, b]$ ,  $g_n$  restricted to  $t_i$  to  $t_{i+1}$  it is a polynomial of degree less than or equal to 3, so on

the interval open interval  $t_i$  to  $t_{i+1}$ , our  $g_n$  will be infinitely differentiable, it being a polynomial.

When you look at say interval  $t_1$  to  $t_2$  and  $t_2$  to  $t_3$ , here we have one cubic polynomial say  $p_1$  here you have another cubic polynomial  $p_2$ , so on the open interval  $t_1$  to  $t_2$   $p_1$  is infinitely many times differentiable. On the open interval  $t_2$  to  $t_3$   $p_2$  is infinitely many times differentiable, the problem is the partition point  $t_2$  that is where the 2 polynomials we are joining them together.

So, thus what will come into picture will be the interior partition points  $t_1$  to  $t_2$  to  $t_3$  to  $t_n$  minus 1, when you look at  $t_0$  there is nothing on the left for  $t_n$  there is nothing on the right, so that is why we need to equate the second derivatives only at the interior node points.

(Refer Slide Time: 33:51)

$$P_i''(t_{i+}) = \frac{6g_n[t_i, t_{i+1}] - 4g_n'(t_i) - 2g_n'(t_{i+1})}{h}$$

$$P_{i-1}''(t_{i-}) = \frac{-6g_n[t_{i-1}, t_i] + 4g_n'(t_i) + 2g_n'(t_{i-1})}{h}$$

$$\Rightarrow g_n'(t_{i-1}) + 4g_n'(t_i) + g_n'(t_{i+1}) = 3\{g_n[t_i, t_{i+1}] + g_n[t_{i-1}, t_i]\}$$

$$= 3 \frac{g_n(t_{i+1}) - g_n(t_{i-1})}{h} = \beta_i, \quad i = 1, 2, \dots, n-1$$

$g_n'(t_i) : n+1$  unknowns

$g_n(t_i) = f(t_i), i = 0, 1, \dots, n : \text{Given}$

We have got a system of equations  $g_n'$  at  $t_i$  minus 1 plus 4 times  $g_n'$  at  $t_i$  plus  $g_n'$  at  $t_{i+1}$  is equal to  $\beta_i$ ,  $i$  going from 1 to up to  $n$  minus 1, so these are  $n$  minus 1 equations, whereas unknowns are going to be  $g_n'$  at  $t_0$ ,  $g_n'$  at  $t_1$ ,  $g_n'$  at  $t_n$ , so we have got  $n$  plus 1 unknowns.

So  $n$  minus 1 equation and  $n$  plus 1 unknowns, so it is going to be undetermined system and we will have 2 variables to be free and hence, in order to do the fix the uniqueness or in order to determine  $g_n$  uniquely we add 2 extra conditions.

So, in this case we have got the we consider or the end condition which we put is second derivative at 2 end points it should be equal to 0, so  $g_n$  is the approximating function which is Piecewise Cubic, it is 2 times continuously differentiable and we put that  $g_n$  double dash at  $a$  is equal to  $g_n$  double dash at  $b$  is equal to 0. This condition is known as natural end condition, because it comes from a minimization problem. When the cubic spline they were discovered, they were considered or they came as solution of a minimization problem, but what happens is these conditions they are arbitrary in the sense that we are trying to approximate a function  $f$ , this function  $f$  may not have second derivatives to be equal to 0 at the 2 end point.

So, if this is not the case then our natural end conditions they will have the error to be only less than or equal to constant times  $h$  square, so see in case of Piecewise Linear Interpolation we had the error to be less than or equal to constant times  $h$  square and it is much easier to construct Piecewise Linear Interpolation. Of course for Piecewise Linear Interpolation we had only continuity now this function is going to be 2 times continuously differentiable, but still there is a loss of order of convergence, so then one looks at what one will have like to have is the best of both that your error should be less than or equal to constant times  $h$  raise to 4 and it should depend only on the function value, may be even the derivative values at the two end points are also not known, so that gives raise to one more condition, so before we consider that condition which depends only on the function values and which has order of convergence  $h$  raise to 4.

(Refer Slide Time: 42:41)

2) Natural End Conditions :  $g_n''(a) = g_n''(b) = 0$

For  $x \in [a, t_1] = [t_0, t_1]$ ,

$$g_n''(a) = P_0''(t_0^+)$$

$$= \frac{6g_n[t_0, t_1] - 4g_n'(t_0) - 2g_n'(t_1)}{h} = 0$$

$$\Rightarrow 2g_n'(t_0) + g_n'(t_1) = 3 \frac{g_n(t_1) - g_n(t_0)}{h}$$

Similarly,  $g_n''(b) = 0 \Rightarrow$

$$g_n'(t_{n-1}) + 2g_n'(t_n) = 3 \frac{g_n(t_n) - g_n(t_{n-1})}{h}$$

Let us, quickly look at the system of equations in case of the natural end conditions, so we have  $g''(a) = 0$ ,  $g''(b) = 0$ ,  $g''(a)$  is going to be second derivative  $p_0''$  at  $p_0$  plus, so we have got the formula, so you substitute that formula we had the formula for  $p_i''$  at  $t_i$  plus in that formula you put  $i$  is equal to 0 and then we get the formula which involves the value of the function  $g$  at  $t_0$  and  $t_1$  and value of the derivative of  $g$  at  $t_0$  and  $t_1$  keeping on the left the unknowns  $g'(t_0)$  and  $g'(t_1)$  and on the right hand side the known values which are  $g(t_1)$  and  $g(t_0)$ , they are respectively equal to  $f(t_1)$  and  $f(t_0)$ , so we get an equation.

Similarly, look at the  $g''(b) = 0$  and obtain an a condition which involves the derivatives of  $g$  at  $t_{n-1}$  and  $t_n$  and a function values, so we get 2 additional equations, we already had  $n-1$  equation to that add these 2 equations, so total there will be  $n+1$  equations in  $n+1$  unknowns with the coefficient matrix to be diagonally dominant and hence invertible.

(Refer Slide Time: 44:13)

$$\begin{bmatrix} 2 & 1 & 0 & 0 & \dots & 0 \\ 1 & 4 & 1 & 0 & \dots & 0 \\ 0 & 1 & 4 & 1 & \dots & 0 \\ \vdots & & & & & \\ 0 & & & & 1 & 4 & 1 \\ 0 & 0 & 0 & 0 & \dots & 1 & 2 \end{bmatrix} \begin{bmatrix} g'_n(t_0) \\ g'_n(t_1) \\ g'_n(t_2) \\ \vdots \\ g'_n(t_{n-1}) \\ g'_n(t_n) \end{bmatrix} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \vdots \\ \beta_{n-1} \\ \beta_n \end{bmatrix}$$

$$\beta_i = 3 \frac{f(t_{i+1}) - f(t_{i-1}))}{h}, \quad \beta_0 = 3 \frac{f(t_1) - f(t_0)}{h},$$

$$i = 1, \dots, n-1 \quad \beta_n = 3 \frac{f(t_n) - f(t_{n-1}))}{h}$$

(Refer Slide Time: 44:47)

Order of Convergence.

1) Complete Cubic Spline Interpolation:  
 $\|f - g_n\|_\infty \leq C h^4$

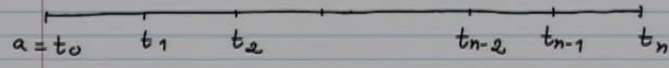

2) Natural End Conditions:  
 $\|f - g_n\|_\infty \leq C h^2$

So, here is the coefficient matrix, it is a tri diagonal matrix with diagonal entries to be 2 in the first and last row and all other diagonal entries to be equal to 4, sub diagonal and super diagonal entries are equal to 1, n plus 1 equations in n plus 1 unknowns, so 1 solves those gets  $g_n$  dash at  $t_i$ 's,  $g_n$  at  $t_i$  they are equal to  $f$  at  $t_i$  and that will completely determine Piecewise Cubic Polynomial which is c 2.

(Refer Slide Time: 45:12)

not-a-knot condition:

$g_n'''(t_1^-) = g_n'''(t_1^+), g_n'''(t_{n-1}^-) = g_n'''(t_{n-1}^+)$   
 $g_n$  reduces to a single cubic polynomial  
in  $[t_0, t_2]$  and in  $[t_{n-2}, t_n]$   
Order of convergence:  $h^4$

Look at the order of convergence, so as I said for complete Cubic Spline Interpolation, it is constant times norm of  $f$  minus  $g_n$  infinity norm to be less than or equal to constant

times  $h$  raised to four for the natural end conditions, it reduces two constant times  $h$  squared, so we look at one more condition which is known as not a knot condition, so in this case what we do is we look at the partition points  $t_1$  and  $t_{n-1}$  only 2 partition points. At these partition points we say that the function should be 3 times continuously differentiable.

So, at all other partition points it is only twice differentiable, but at  $t_1$  and  $t_{n-1}$  we say that it should be three times differentiable, so in the interval  $t_0$  to  $t_1$  it is a polynomial of degree 3, in the interval  $t_1$  to  $t_2$  it is a polynomial of degree 3, then when you say that third derivative should match then it is going to be only a single polynomial in the interval  $t_0$  to  $t_2$  and in the interval  $t_{n-1}$ ,  $t_{n-2}$  to  $t_n$  similarly it is going to be a single cubic polynomial, so such a polynomial is going to be unique and in this case the order of convergence it is restored to  $h$  raised to 4. Now this completes our polynomial interpolation.

Our next topic is numerical integration, so what we are going to do is now we have got interpolating polynomial, so the function  $f(x)$  is equal to interpolating polynomial  $p_n(x)$  plus there is some error, then  $\int_a^b f(x) dx$  is going to be approximately equal to  $\int_a^b p_n(x) dx$ ,  $p_n$  is the interpolating polynomial interpolating given function at  $x_0, x_1, \dots, x_n$ , so depending on the choice of  $n$  and choice of the interpolating points we are going to get different numerical quadrature rules, so this going to be the topic of our next lecture.
