

Mathematics in India: From Vedic Period to Modern Times
Prof. M.S. Sriram
University of Madras, Chennai

Lecture-20
Leelavati of Bhaskaracarya 1

So, these of first of the 3 lectures on the famous work (FL).

(Refer Slide Time: 00:16)

Outline

- ▶ Introduction, Importance of *Līlāvati*
- ▶ Arithmetical operations: Inversion method, rule of supposition
- ▶ Solution of quadratic equations
- ▶ Mixtures
- ▶ Combinations, progressions.
- ▶ Plane figures: Application of Right Triangles.

◀ ◁ ▷ ▶ ↻ 🔍

So, this give the outline, so introduction importance of (FL) then arithmetical operations which he considers and some particular methods which are he considers as a important and solution of quadratic equations. So, then in many other text earlier text, mixtures then combinations and progressions, and finally plane figures with application to right angles specifically.

(Refer Slide Time: 00:46)

Introduction

Bhāskara II: Perhaps the most well known name among the ancient Indian astronomer-mathematicians. Designated as Bhāskara-II to differentiate him from his earlier namesake, who lived in the seventh century CE (Bhāskara-I).

According to his own statement in his *Golādhyāya*, was born in saka 1036 or 1114 CE. He also adds that he came from *Vijjalavīda* near the *Sahyādri* mountain. → Bijapur? S.B. Dixit → Bhāskara's original home was Pāṭan in (*Khāndes*) → Inscription lists his grandfather, father, son and grandson: Manoratha, Maheśvara, Lakṣmīdhara, Cangadeva respectively.

Bhāskara's *Līlāvati*: A standard work of Indian Mathematics: *Paṭī* or *Paṭīgaṇita*: elementary mathematics covering arithmetic, algebra, geometry and mensuration. Still used as a textbook in Sanskrit institutions in India. Composed around 1150 CE.

◀ ▶ ↻ 🔍

(FL) perhaps the most well known among the ancient Indian astronomer-mathematicians so, most people would have heard his name in India. And he is designated as (FL) to distinguish him from his predecessor is namesake (FL) 1, who lived in the seventh century. So, according to his own statement in the word (FL) which is the part of his famous work (FL) who will born in (FL) year 1036 or which corresponds to 11, 14 common era, so he also adds that he came from (FL) near (FL) mountain.

So, some people speculated that it was (FL) in northern Karnataka but many others do not think so, for instance the famous historian of mathematics Indian mathematics and astronomy (FL) who wrote famous work on Indian astronomy and mathematics in the 20th century beginning. He feels that the Bhaskara's original home was spotted in (FL) is the part of Maharashtra and the reason is inscription is here with list his grandfather, father, son and grandson whose names are Manoratha, Mahesvara, Laksmiidhara and Cangadeva respectively.

So, Bhaskara's (FL) is a standard work Indian mathematics it is a (FL), so elementary mathematics covering arithmetic, algebra, geometry and mesuration. In fact we will see that there is at least resultant trigonometry also in this work and what is important is that you know it is still used as a textbook in Sanskrit institutions in India like you know the (FL) courses and things like that, so they use (FL) and it is composed around 1150 Common Era.

(Refer Slide Time: 02:48)

Commentaries and other works

Many commentaries: Parameśvara (about 1430), Gaṇeśa (*Buddhivilāsinī*) (1545), Sūryadāsa, Munīśvara (about 1635), and Rāmakṛṣṇa (1687). According to R. C. Gupta, a well known historian of Indian mathematics, the best traditional commentary is *Kriyākramakarī* (C. 1534) of Śaṅkara Vāriyar and Mahiṣamaṅgala Nārāyaṇa (who compiled this after the demise of Śaṅkara). Number of commentaries and versions in regional languages, Kannada, Telugu, etc., Three Persian translations are known: Abul-Fayd Faydi (1587 CE). My lectures based on Colebrook's translation (1817) reprinted along with the original Sanskrit text and commentaries with notes by H. C. Banerji. Others works of Bhāskara: *Bījagaṇita* (Algebra), one of the most important treatises on Indian algebra. *Siddhāntaśiromaṇi*: comprising *Grahaṅgaṇita* and *Golādhyāya* also very popular. Other work *Karaṅakutūhala* (epoch 1183 CE).

There are many commentaries on his famous work there is one (FL) around 1430 CE, so then one of the most famous ones which explains (FL) in considerable detail is (FL) of a (FL) composed around 1545, so in there is a commentary (FL) then one by (FL) around 1635, the one Ramakrishna commentary by Ramakrishna around 1687 and according to R.C. Gupta a well known historian of Indian mathematics the best additional commentaries (FL) composed around 1534 of (FL).

And his thought that he could not complete it and he is completed by 1 (FL) Nararyana who compile this after the demise of shankara. So, this is a very detailed commentary some of our colleagues are working on this detailed work the number of commentaries and versions in regional languages like Kanada, telugu etc., and now of course they in the lot of a literature available in (FL) in other languages also Hindi and so on and so forth yeah tree Persian translations are known one of the famous one is (FL) so it is around 1587 CE.

So, my lectures are based on (FL) books (FL) books translation which he did in the 19th century beginning base he which based of the original Sanskrit text and commentaries with notes by S.C Banarjee, now of course at many other accessible works in (FL) for instance there is work by name spelling, (FL) published by (FL). So, that is fairly easily accessible and easy to comprehend and there are many other work books on (FL) in the regional languages.

I mean which are modern you know which explains things in the modern notation or others I for instance no 1 work in Canada. So, there must be in other languages also now there are other works are Bhaskara (FL) which is also very famous work which will be discussed later in the lecture series. So, then (FL) which is comprising 2 parts called (FL) and (FL). Sometimes of course (FL) people talk as if that compost of 4 parts you know (FL) and (FL), so (FL) in the.

This is here I am different to the astronomy part which is (FL) and (FL) in the another work called (FL) who you know where he make some you know corrections to the parameters for the planets, the composed around 1183 common era.

(Refer Slide Time: 06:08)

Operations of arithmetic

Līlāvati: Rules and Examples in about 270 Verses.
 Chapter 1 on weights and measures, money denominations.
 Numeration upto 10^{14} .
 Eight operations of arithmetic.

- i) Addition and subtraction
- ii) Multiplication
 - a) $a_1 \dots a_n \times B$. Multiply a_n by A , a_{n-1} by A etc. and add (taking into account place values).
 - b) $A(b + c) = Ab + Ac$.
 - c) $A \times B = Ax \times \frac{B}{x}$, where x is a factor of B .
 - d) $ab = a(b \pm c \mp c) = a(b \pm c) \mp ac$.
- iii) Division: Remove common factors.

So, (FL) has rules and lot of examples in about 270verses the chapter 1 is an weights and measures, so which is there in many other works also you know they discuss the way it is you know and measures of time measures of length, measures of volume and so on and then money denominations and there is a numeration there is up to 10 to the power of 14, so then he discusses 8 operations of arithmetic addition and subtraction then multiplication, so suppose you have number A_1 to A_n if you multiply by the B .

Then multiply an by B I am sorry this should replace capital A by capital B here yeah multiply A_n by B a_{n-1} by B etc., and add all of them of course taking into account the place values because here it an corresponds to an itself. The a_{n-1} you see here that will correspond to tenth

place right, so you have to take this into account, then if you have a number a then multiply by b+c that is $Ab+Ac$ all these things are stated you know see this is the modern algebra all this thing are stated you know it is called a distributive law.

So, that is interesting that they you know take they are careful about this things if we saw that in (FL) also. So, then sometimes it maybe simpler to write a into b as Ax into b by x where x is the factor of b and carry on the multiplication then if you have a into b then sometimes it may be easy to write it as A into $B\pm c$ - or +c, so which is equal to a into $b\pm c$ -or+ Ac , so then if you have division you remove common factors okay.

(Refer Slide Time: 08:12)

Squaring , Squareroots etc.

Verses 18-19. Squaring

i)

$$(a_1 + \dots + a_n)^2 = a_n^2 + 2a_n(a_1 + \dots + a_{n-1}) + a_{n-1}^2 + 2a_{n-1}(a_1 + \dots + a_{n-2}) + \dots + a_2^2 + 2a_2a_1 + a_1^2.$$

ii) $(a + b)^2 = a^2 + 2ab + b^2.$

iii) $a^2 = (a + b)(a - b) + b^2.$

Verses 21-22: Square root and example.
 Verses 23-26: Cube and example.
 Verse 27-28: Cube root: Standard Indian method.

So, squaring, square roots etc., I will not spend much time upon those because earlier works work considered in great detail here in this lecture series, for instance if you have this a_n +etc., an whole square. So, then it is equal to an square you write first then 2 an into all are rest of the other digits okay and rather this is not this thing is just the a_1 +etc., I am not writing number as such the sum of these things, so it is 2 an into a_1 +etc., but of course decimal plays system is in the background you know the back of this everything.

And then similarly next is you take of a_{n-1} square this and then multiply twice of that and multiply with the other numbers and so on. And specifically if you have 2 digits so then $a+b$ whole square is equal to a square+2 ab+b square. Then a square sometimes it is convenient to

write it as $a+b$ into $a-b+b$ square. So, that depends upon the particular situation where you know this may be simpler for manipulations.

So, then square root he takes and you know explains a method of extracting the root, similarly in this 23, 26 he takes the cube and takes an example, so then he takes the cube root which is standard Indian method which we already discuss in the context of Aryabhattiya and (FL).

(Refer Slide Time: 09:48)

Multiplication with fractions

Fractions: $\frac{a}{b} \cdot \frac{c}{d} = \frac{ad}{bd}, \frac{cb}{db}$ for addition, subtraction etc.,

Verse 32-33:

$$\frac{a}{b} \times \frac{c}{d} \times \dots = \frac{ac\dots}{bd\dots}$$

$$\frac{a}{b} + \frac{c}{d} \times \frac{a}{b} + \frac{e}{f} \left(\frac{a}{b} + \frac{c}{d} \times \frac{a}{b} \right) + \frac{g}{h} \left[\frac{a}{b} + \frac{c}{d} \times \frac{a}{b} + \frac{e}{f} \left(\quad \right) \right] \dots$$

$$= \frac{a(d+c)(e+f)(g+h)\dots}{bdfh\dots}$$

Division of fractions.

$$\frac{a}{d} \div \frac{b}{c} = \frac{ad}{bc}$$

So, fractions, so sometimes it is you know convenient to do them to common denominator suppose you have a by b and c by d , so a by b is written as ad by bd and c by d is written as cb by db . So, the common you have multiply the denominators basically of course for many other numbers you carry on like this if it is specifically it is mentioned that a by b into c by d etc., etc., so multiply all are numerators and divide by product of all the denominators.

Then this kind of a thing you know suppose you have a by b then they are fraction c/d of a a/b then the fraction e/f of this resultant so, like that. So, this is considered in many this kind of a you know representation for many problems it is considered in the Indian works at similarly g/h into this whole thing so, then that is equal to it is stated you know. He gives the simplified form a into $d+c$ into $e+$, f into $g+$ etc. divided by the all the denominators basically product of all the denominators.

Then it consider division of fractions so, a/b divided by c/d is ad/bc okay.

(Refer Slide Time: 11:11)

Operations with zero

Verses 44-45 :

योगे खं क्षेपसमं वर्गादौ खं खभाजितो राशिः।

खहरः स्यात् खगुणः खं खगुणश्चिन्त्यश्च शेषविधौ ॥ ४४ ॥

शून्ये गुणके जाते खं हारश्चेत् पुनस्तदा राशिः।

अविकृत एव ज्ञेयस्तथैव खेनोनितश्च युतः ॥ ४५ ॥

"In addition, zero makes the sum equal to the additive. In involution and (evolution) the result is zero. A definite quantity, divided by zero, is the submultiple of nought. The product of zero is nought: but it must be retained as a multiple of zero, if any operations impend. Zero having become a multiplier, should nought afterwards become a divisor, the definite quantity must be understood to be unchanged. So likewise any quantity, to which zero is added, or from which it is subtracted, (is unaltered).

So, next he considered operations with 0 (FL) In addition zero makes the sum equal to the additive in involution and (evolution) the result is zero. A definite quantity, divided by zero, is the sub multiple of nought. The product of zero is nought but it must be retained as a multiple of zero, if any operations is impend.

Zero having becoming a multiplier should nought afterwards become a divisor. The definite quantity must be understood to be unchanged. So, likewise any quantity to which zero is added or from which it is **sub** subtracted (is unaltered).

(Refer Slide Time: 12:17)

Operations with zero

$a \pm 0 = a$, $\frac{a}{0} = Kha-hara$: a fraction with zero for its denominator.

(In *Bījagaṇita*. Gaṇeśa: Infinity).

$$a \times 0 = 0$$

But it must retained as a multiple of zero, if further operations, impend. "Zero having become a multiplier, should nought afterwards become a divisor, the definite quantity must be understood to be unchanged".

$$a \times \frac{0}{0} = a? \quad (\text{But } \frac{0}{0} \text{ is indeterminate})$$

So, what of course he is saying is that suppose you have $a \pm 0$ then that is equal to a , so that a remains unchanged then $a/0$ is called it as (FL) a fraction with 0 denominator, it does not go explain that in great detail here because he consider things these things is (FL) you know, operation with 0 are considered in more detail in his work (FL) but he just say that he has (FL) and (FL) in the commentary mention that it is a infinity.

So, remember there would have a conclusion about that in (FL), now you know it is clear, so that a into 0 is 0, then what happens when a into 0 by 0 it must be retain in the multiple of 0 further operations impend, see suppose a into 0 then do not just put it is equal to 0 because afterwards some division by 0 maybe there. So, you retain that 0 having become a multiplier should not afterwards become a divisor the definite quantity must be understood be un change.

Perhaps he saying that a into suppose you have you know multiply by 0 on divide by 0, that is a itself. So, it is not very clear in this context this will be explained in detail later but now of course we know that you cannot just put it as a indeterminate you know $0/0$ that depends upon the way the $0/0$ comes but here the confusion is there it appears as if is writing it like this we do not know which is not correct. Here I do not have any this thing you know and he is not miss should that is a translation you know.

In fact it could be in not itself that is a peculiarity of his translation maybe his emphasizes it you know ought and knot kind of thing probably yeah.

(Refer Slide Time: 14:20)

Inversion method

Inversion method to find the solution of a problem in Verse 47-48 :

छेदं गुणं गुणं छेदं वर्गं मूलं पदं कृतिम्।
 ऋणं स्वं स्वमृणं कुर्याद् दृश्ये राशिप्रसिद्धये ॥ ४७ ॥
 अथ स्वांशाधिकोने तु लवाद्घोने हरो हरः।
 अंशस्त्वविकृतस्तत्र विलोमे शेषमुक्तवत् ॥ ४८ ॥

"To investigate a quantity, one being given, make the divisor a multiplier; and the multiplier, a divisor; the square, a root; and the root, a square; turn the negative into positive and the positive into negative. If a quantity is to be increased or diminished by its own proportional part, let the (lower) denominator, being the increased or diminished by its numerator, becomes the (corrected) denominator, and the numerator remain uncharged"; and then proceed with the other operations of inversion, as before directed."

(* If we have $1 + \frac{a}{b} = \frac{a+b}{b}$, in the inversion, it will be $\frac{b}{a+b}$.)

Then he considers what is known as inversion method the find a solution of a problem , for he is what he says (FL). So, to investigate a quantity 1 being given make the divisor a multiplier and the multiplier, a divisor, the square, a root etc., etc., okay. So, what he is trying to say we should understand what he is if you see some example it will be clear.

(Refer Slide Time: 15:07)

Inversion method: Example

Example in Verse 49 :

यस्त्रिभ्रस्त्रिभिरन्वितः स्वचरणैर्भक्तस्ततः सप्तभिः
 स्वत्र्यंशेन विवर्जितः स्वगुणितो हीनो द्विपञ्चाशता।
 तन्मूले ऽष्टयुते हते च दशभिर्जातं द्वयं ब्रूहि तं
 राशिं वेत्सि हि चञ्चलाक्षि विमलां
 वामे विलोमक्रियाम् ॥ ४९ ॥

"Pretty girl, with tremulous eyes, if thou know the correct method of inversion, tell me the number, which multiplied by three and added to three quarters of the product, and divided by seven, and reduced by subtraction of half a third part of the quotient and then multiplied into itself, and having fiftytwo subtracted from the product and the square root of the remainder extracted, and eight added and the sum divided by ten yields two (2)."

So, that is if you are saying a some operations are carried out and then you know the result is given okay and what is that original number. So, he is saying that you know you have to go in the

inverse manner, so by, by when I deal with a deal with a example it will be clear. So, for instance he gives one example inverse 49 (FL) you know inversion you know do it the other way kind of a thing, so (FL) pretty girl with tremulous eyes, if thou know the correct method of inversion, tell me the which multiplied by 3 and added to three quarters of the product.

And divided by 7 and reduce by subtraction of half a third part of the quotient and then multiplied into itself and having 52 subtracted from the product and the square roots are remainder extracted and 8 added and the sum divided by 10 is 2, so this is a final result okay. So, you have done various operations on the number the final result is 2, then what is that number you see that is what is this thing okay.

(Refer Slide Time: 16:37)

Inversion method: Example

$$\frac{1}{10} \left[8 + \sqrt{-52 + \left[\underbrace{\left(1 - \frac{1}{3}\right) \frac{1}{7}}_{\frac{2}{3}} \underbrace{\left(1 - \frac{3}{4}\right)}_{\frac{7}{4}} \times 3 \times x \right]^2} \right] = 2$$

Answer:

$$x = \sqrt{(2 \times 10 - 8)^2 + 52} \times \frac{3}{2} \times \frac{4}{7} \times \frac{1}{3} = 28.$$

So, essentially he is saying you know if you translate that verse into our you know the an equation we know familiar with you know this writing equations in this form, so what he is saying you know the one tenth you know say x is there, so x into 3 okay. So, then you are 1-3/4 multiplied by that 1/7 is there 1-1/3 is there the whole thing square is that is what is he is saying right which multiply by 3 and added to 3 quarters of the product and divided by 7 and reduce by subtraction of half.

The third part of the quotient and then multiplied into itself right, so that is what it is then you subtract -52 then take the square root of that then add 8 then divide by 10 that is 2, so now what

he is saying to find the answer you do it the reverse way, so it is take 2, 2 is a answer you take that then see here 1/10 was given in the problem, so now you take it as 10, 2*10, so addition 8 was there here you -8 okay. So, then next square root is there then you have to take the square root then – is here, here you take +.

So, then here 2/3 is there you make it as 3/2 then here you see the whole thing is 7/4, so write it as 4/7 and a 3 is there 1/3, so this whole thing is equal to the answer which is 28. So, I mean this is inverted you know see 2 when you to in the modern you to taken into 10 write 10, then -8 right, square root of this number is 2*10-8 then you have to take the square of that it is, so you have to take the square, so like that, so that is the inverse method.

So, then the another method called rule of supposition or false position, I mean these are somewhat implied in the modern methods.

(Refer Slide Time: 18:45)

Rule of false position

Verse 50:

उद्देशकालापवदिष्टराशिः क्षुण्णो हृतोऽथै रहितो युतो वा ।
इष्टाहतं दृष्टमनेन भक्तं राशिर्भवेत् प्रोक्तमितीष्टकर्म ॥ ५० ॥

"Any number assumed at pleasure is treated as specified in the particular question, being multiplied and divided, raised or diminished by fractions; then the given quantity, being multiplied by the assumed and divided by that (which has been found) yields th number sought. This is called the process of supposition."

Let some operations be done on the number x , represent it as A . Let it yield $A(x) = y$. Take any x' and do the same operations. Let it yield y' , $A(x') = y'$. Then

$$x = y \times \frac{x'}{(y')}$$

◀ ▶ ⏪ ⏩ 🔍 🔄

But in here explaining it you know in explicitly, so suppose this operates in the following ((18:54)) what he is trying to say is the following. Suppose you have some operations you do on some number x okay we do not know that number x operations it do would on the number x and get the result y okay you know y see you have to find x , so what he is saying that take any number explain okay and do all this operations a on that okay and then suppose you get the result y prime.

So, then the result will be x prime/y prime into y, so that is by rule of proportions of course here you should be doing only squaring etc., should not be there it should be what is known as linear operation you know otherwise you will not get that. So, what he is trying to say is you know then you know if you take the number some example it will be clear.

(Refer Slide Time: 19:47)

Rule of false position

Example in Verse 51.

पञ्चमः स्वत्रिभागो नो दशभक्तः समन्वितः ।
राशित्र्यंशार्धपादैः स्यात् को राशिर्द्वानसप्ततिः ॥ ५१ ॥

* What is that number, which multiplied by 5 and having the third part of the product subtracted and the remainder divided by ten, and one-third, a half and a quarter of the original quantity added, gives two less than seventy?*

Solution: Multiplier 5. Subtractive $\frac{1}{3}$ of itself. Divisor 10. Additive $\frac{1}{3}, \frac{1}{2}, \frac{1}{4}$, of the quantity.

Given $68 = y$. Take $x' = 3$; $5 \times 3 = 15$, $(1 - \frac{1}{3})15 = 10$; $\frac{1}{10} \times 10 = 1$;
 $1 + 3(\frac{1}{3} + \frac{1}{2} + \frac{1}{4}) = \frac{17}{4}$; This is y' . So, $y' = \frac{17}{4}$.

$$\therefore x = y \times \frac{x'}{y'} = 68 \times \frac{3}{\frac{17}{4}} = 48.$$

One gets $x = 48$, whatever value one chooses for x' . y' will be correspondingly different.

(FL) this is the example is giving (FL) what is that number which multiplied by 5 and having the third part of the product subtracted in the remainder divided by 10 and one third a half and a quarter at the original quantity added gives 2 less than 17 see here multiplied by 5. So, you write it as multiplier 5 third part of the product subtracted subtractive one third of itself.

So, now the finally what to get is 2 less than 70 so, 68 68 is y you have to find x. So, now take x prime is equal to 3 you do all these all operations and x prime okay. So, multiplied by 5 into 3 is 15. Then having the third part subtracted $1 - \frac{1}{3} * 15$ is 10 then divide by 10 $\frac{1}{10} * 10$ is 1. Then add third part of the $1 + \frac{1}{3}$ half and $\frac{1}{4}$ add all of them and multiplied by the number. So, the you have taken it as 3 and then add 1 okay added okay.

So, $\frac{17}{4}$ this is y prime so, if you start from 3 you get y $\frac{17}{4}$ so, but so, if the this is a quantity the original quantity is 3. Then the result is $\frac{17}{4}$ but if the result is 68 what is the original quantity is just a rule of proportion. So, x is y into x prime/ y prime so, 68 into so, whatever you

took so, suppose supposition 3 and got whatever result you got divide by this. And multiplied by the result so, this is 48 so, one gets 48 of course x prime you can take anything.

Instead of x prime is equal to 3 you can take 6 or 60 or whatever you can do that similarly correspondingly y prime will change. So, then x prime /y prime into x prime, so that will be the same quantity into result, with that will be the same quantity.

(Refer Slide Time: 22:10)

Saṅkramaṇa

Rule of concurrence or '*Saṅkramaṇa*'.

Verse 55:

योगोऽन्तरेणोनयुतोऽर्धितस्तौ
राशौ स्मृतौ सङ्गमणाख्यमेतत् ॥ ५५ ॥

"The sum with the difference added or subtracted, being halved, gives the two quantities. This is termed Concurrence."

If $x + y = k$ and $x - y = l$ where k and l are given quantities.

$$x = \frac{1}{2}(k + l) \text{ and } y = \frac{1}{2}(k - l)$$

Verse 57. If $x - y$ and $x^2 - y^2$ are given, find $x + y = \frac{x^2 - y^2}{x - y}$.

Then x and y are found by *Saṅkramaṇa*.

◀ ▶ ⏪ ⏩ 🔍 🔄

So, that is the so, now it is called the rule of false position so, now it is discusses what is known as sankramana. So, it is the very standard thing only you know this kind of things comes various places but various places so, that is what they stating is (FL). So, what he saying the sum with the difference added or subtracted being halved gives the two quantities this is termed Concurrence or sankramana, so what is the this is very simple thing. Suppose you are giving the sum of two numbers and difference of two numbers.

Then what are the two numbers that is the straight forward. So, if $x+y$ is k and $x-y$ is l then clearly x is half of $k+l$ and y is equal to half $k-l$. Of course you can extend it into straightly different kind of problems based on this advanced things based on this. Suppose if $x-y$ and $x^2 - y^2$ are given then you have to find $x+y$ first $x^2 - y^2 / x - y$. Then x and y are found by sankramana in fact we will see that later.

(Refer Slide Time: 23:25)

Rational Squares

Verse 59 and 60: Examples of generation of rational squares:
Consider the pairs

a)
$$x_1 = \frac{1}{2n}(8n^2 - 1), x_2 = \frac{1}{2} \left\{ \frac{1}{2n}(8n^2 - 1) \right\}^2 + 1,$$

b)
$$x_1 = \frac{1}{2n} + n, x_2 = 1,$$

c)
$$x_1 = 8n^4 + 1, x_2 = 8n^3.$$

For all these pairs, $x_1^2 + x_2^2 - 1$ are squares.

Narayana punita will discuss for more things you know some more difficult slightly the more difficult problems are given. Then you reduced to sankraman and then okay so, now generation of various rational squares etc.. the various rational triangles rationales, figures, and all that you know. You have to generate it okay so, as per you know pointed out you know we generate various words you see which are valued kind of a thing.

So, similarly you generate various the same kind of you know mind set seems to be there you know. It generate various kinds of figures or the kind of a thing miss some stipulation you know that all the sides must be rational or all the others segments must be rational and so on and so for. The for instance if you takes you know suppose he says that you consider two quantities x_1 and x_2 suppose you are stipulating that $x_1^2 + x_2^2 - 1$ or squares.

So, this must be expressible as some quantity square square of that okay. So, then one particular kind of solution is x_1 , if you take this if you take any n integer. You take x_1 is this then x_2 is this so, then you get if you take this sum of the squares and reduced 1 then that will be a x square okay. So, similarly if x_1 is $1/2n+n$ and x_2 is 1. You will get a square for this and if x_1 is 8 into the power of 4+1 and $8n$ cube again.

(Refer Slide Time: 25:05)

Solution of Quadratic equations

Next, Bhāskara gives the solution of a quadratic equation .
Verse 62-63: Suppose we have

$$x \pm a\sqrt{x} = b$$

$$\text{Then } \sqrt{x} = \mp \frac{a}{2} + \sqrt{b + (a/2)^2} \text{ and } x = \left(\mp \frac{a}{2} + \sqrt{b + (a/2)^2} \right)^2 .$$

(At least here, only one root is being talked about)

Similarly, given: $x + \frac{c}{d}x \pm a\sqrt{x} = b$, we obtain

$$x \pm \frac{a\sqrt{x}}{1 \pm \frac{c}{d}} = \frac{b}{1 \pm \frac{c}{d}} .$$

Then proceed as before to find \sqrt{x} and then x .

The sum of the squares-1 it will be a square you know that it will be some different quantity square you see I mean that quantity must not involve square root obviously you see. So, it must be some rational thing and then you square kind of a thing that is the what is then you cube the solution of a quadratic equation (FL) in the even earlier also we had seen that it is the expressed as the like this $x+a$ a root x is equal to b a solving for root x and then squaring it to get x .

So, then it is stated that root x is equal to if $+$ or $-$ a is there so, is $-$ or $+$ will be there it will come+ this. So, $+a/2+$ square root of $b+a/2$ whole square whole thing square that is the solution. So, here atleast you know only one root is being talked about. Because in many examples then negative root will not make sense so, he is actually talking one root only. So, it is standard thing you know that is ax^2+bx^2+c is equal to 0 you know.

You know the solution in the modern method at least the modern way of a expressing it. So, the same thing see here instead of b you got a and things like that you know. And here you know it is the right hand side so, you have to be careful you will get this at the solution so, then similarly if you have he considers you know suppose you have $x+c/d$ x kind of everything you know. So, then this reduces to this then proceed has before you find root x and then x okay.

(Refer Slide Time: 26:50)

Quadratic equations: Example

An example in Verse 67.

पार्थः कर्णवधाय मार्गणगणं क्रुद्धो रणे सन्दधे
तस्यार्धेन निवार्य तच्छरणं मूलैश्चतुर्भिर्हयान् ॥
शल्यं षड्विरथेषुभिस्त्रिभिरपि छत्रं ध्वजं कार्मुकं
चिच्छेदास्य शिरः शरेण कति ते यानर्जुनः सन्दधे ॥ ७६ ॥

"The Son of Prtha, irritated in fight, shot a quiver of arrows to slay Karṇa. With half his arrows he parried those of his antagonist; with four times the square root of the quiver-full, he killed his horses; with six arrows, he slew Śalya; with three he demolished the umbrella, standard and bow; and with one, he cut off the head of the foe. How many were the arrows which Arjuna let fly?"

◀ ▶ ◀ ▶ ◀ ▶ ◀ ▶ ◀ ▶ ◀ ▶ ◀ ▶

So, this famous example I will consider many of the you know famous examples which Baskara has you know by which are which are they are in that axis if we are illustrating various procedures so, (FL) the son of prtha irritated in fight (FL) okay shot a quiver of arrows to stay karna okay (FL) to slay karna so, shot a quiver so, a quiver of this of arrows (FL) with half his arrows he parried those of his antagonist (FL) is karna or this thing.

Then (FL) with four times the square root of the quiver-full, he killed his horses (FL) okay with six arrows he slew (FL) with three demolished umbrella (FL) umbrella standard and bow okay (FL). Then he cut off the head of the remaining this thing arrow cut off the head of the foe with the remaining I know. How many were the arrows which Arjuna let fly so, this is so, essentially son of prtha yeah (FL) okay that is the translation okay. You can come a tied as (FL) prtha irritated in this thing yeah sometimes prtha has son of (FL) you know kind of a thing is a Sanskrit.

(Refer Slide Time: 29:07)

Solution of Quadratic equations

Let x denote the number of arrows.

$$\frac{1}{2} + 4\sqrt{x} + 6 + 3 + 1 = x$$

$$\frac{1}{2}x - 4\sqrt{x} - 10 = 0$$

$$\therefore x - 8\sqrt{x} - 20 = 0$$

$$\sqrt{x} = 10; x = 100.$$

(Here $\sqrt{x} = -2$ is also a solution. But in the problem \sqrt{x} has to be +ve.)

Rule of 3, 5, 7, 9, ...

10

So, what is saying is half+4 root x+6+3+1 that is equal to x. So, in fact this must be half x half the arrows half x+4 root x+6+3+1 is equal to x, so these what to get x-8 root x -20 0. So, from the method that he has formula he has given for the solution root x is equal to 10 is x is 100. Of course root x-2 is also a solution in fact there is a valid solution for this.

But in the problem root x has to be negative because remember that he has taken you know four times, the square root of the with four times the square root the killed is arrows. So, the square root x also must be positive so, he is taking the positive root and the solution is this.

(Refer Slide Time: 30:02)

Investigation of mixtures

Rule in Verse 90.

अथ प्राणैर्गुणिताः स्वकालाः प्रतीतकालभ्रफलोद्धृतास्ते ।
स्वयोगभक्ताश्च विमिश्रनिष्ठाः प्रयुक्तखण्डानि पृथग् भवन्ति ॥

"The arguments taken into their respective times one divided by the fruit taken into the elapsed times; the several quotients, divided by their sum, and multiplied by the mixed quantity, and the parts as severally lent."

20

Then it talks about the rule of 3, 5, 7, 9 and all that similar to what he is but I forget to mention that apart from the 0 Brahmagupta and mahavira and he had there others also eminent (FL) and then sripati who wrote a very famous work was siddhantasekara which also the mathematics section. So, some of the results are taken from there also you know So, then he discusses investigation mixtures (FL) is a argument taken into the respective times.

One divided by the fruit taken into a elapsed times the several quotients divided by their sum and multiplied by the mix quantity and a parts as severally lent.

(Refer Slide Time: 31:11)

Mixtures

Let x, y, z be the portions lent at r_1, r_2, r_3 percent per month and let $I =$ common interest in t_1, t_2, t_3 months respectively.

Let $x + y + z = a$, a given quantity. Then,

$$\frac{x \times r_1 \times t_1}{100} = \frac{y \times r_2 \times t_2}{100} = \frac{z \times r_3 \times t_3}{100} = I.$$

$$\therefore x : y : z :: \frac{100 \times 1}{r_1 \times t_1} : \frac{100 \times 1}{r_2 \times t_2} : \frac{100 \times 1}{r_3 \times t_3}.$$

$$x = \frac{100 \times 1}{r_1 \times t_1} \times \frac{a}{\frac{100 \times 1}{r_1 \times t_1} + \frac{100 \times 1}{r_2 \times t_2} + \frac{100 \times 1}{r_3 \times t_3}}$$

Here: Argument 100, Time: 1, fruit: r , elapsed time: t_1 .

Similar expressions for y and z .

So, as usual write the things in the the form which is familiar to us. So, you will be able to understand suppose x, y, z are the portions lent the principle is lent at the interest rate r_1, r_2, r_3 percent per month. And suppose common interest I is equal to common interest in t_1, t_2, t_3 months okay. So, x being lent at rate r_1 for t_1 months, why being lent at rate r_2 for t_2 months z being lent at r_3 rate r_3 for 3 months.

So, the common interest is this so, $x \cdot r_1 \cdot t_1 / 100$ etc... the these equal to common I and what is given is $x+y+z$ so, then one can see that $x:y:z$ is this thing. So, x itself is given by this what is saying $100 \cdot 1 / r_1 t_1$ into the mixed quantity divided by the sum of these. So, that is what is essentially saying a several quotients divided by their sum and multiplied by the mixture quantity. So, that is the several.

(Refer Slide Time: 32:23)

Mixtures: Example

Example in Verse 91:

यत् पञ्चकत्रिकचतुष्कफलेन दत्तं
खण्डैस्त्रिभिर्गणक निष्कशतं षडूनम्।
मासेषु सप्तदशपञ्चसु तुल्यमाप्तं
खण्डत्रयेऽपि हि फलं वद खण्डसंख्याम् ॥ ९१ ॥

"The sum of six less than a hundred *niskas* being lent in three proportion at interest of 5, 3, and 4 percent, an equal interest was obtained on three portions in 7, 10 and 5 months respectively. Tell mathematician, the amount of each portion."

So, I gives an example the sum of six less than a hundred *niskas* being lent in the proportion at interest of 5, 3 and 4 percent at equal interest was obtained on three being lent in three proportions at interest of 5, 3 and 4 proportion is not known. An equal interest for the obtained and 3 portions in 7, 10 and 5 months respectively tell mathematician the amount of each portion (FL) okay (FL) that is the portion you see. Amount of each portion you have to tell.

(Refer Slide Time: 33:02)

Solutions

Here $a = 94$, $r_1 = 5$, $r_2 = 3$, $r_3 = 4$; $t_1 = 7$, $t_2 = 10$, $t_3 = 5$.

Now $r_1 t_1 = 35$, $r_2 t_2 = 30$, $r_3 t_3 = 20$.

$$\therefore \frac{100}{35} + \frac{100}{30} + \frac{100}{20} = \frac{(6 + 7 + 10.5)}{210} \times 100 = \frac{235}{21}$$

$$\therefore x(\text{portion 1}) = \frac{\frac{100}{35} \times 94}{\frac{235}{21}} = \frac{100}{35} \times \frac{21}{235} \times 94 = 24,$$

$$y(\text{portion 2}) = \frac{\frac{100}{30} \times 94}{\frac{235}{21}} = \frac{100}{30} \times \frac{21}{235} \times 94 = 28,$$

$$z(\text{portion 3}) = \frac{\frac{100}{20} \times 94}{\frac{235}{21}} = \frac{100}{20} \times \frac{21}{235} \times 94 = 42.$$

$$\text{Common interest} = i = \frac{24 \times 5 \times 7}{100} = \frac{840}{100} = 8\frac{2}{5}$$

He considers the filling of a cistern from n fountains : Same as in *Gaṇitasārasaṅgraha*

So, essentially here the rates of interest are given r_1 , r_2 , r_3 5, 3 and 4 the number of months is this. The total interest is the same and $r_1 t_1$, $r_2 t_2$, $r_3 t_3$ they are this. And then the amounts are different the total is given amount this thing so, by using is whatever the may procedure is given

which just have to you see you see 100 divided by this. Then 100 divided by 30, 100 divided by 20 you take this had all of them you get this.

So, then this is the result you get so, then whatever the portion one lent so, that is the mixture quantity 94 comes here in the numerator this comes the denominator. And $100/35$ comes in a that particular attaining to one that is this. So, these are the various quantities which are lent and a common interest is this. So, similarly so, next other mixture thing it talks about a filling the of a cistern from n fountains or n pipes. I discuss that in the context of (FL). So, that also he discusses here.

(Refer Slide Time: 34:16)

Another kind of problem involving mixtures

Let there be a mixture of n items. Let the relative proportion of type i in the Mixture = β_i .

\therefore Relative proportion = $\beta_1 : \beta_2 : \dots : \beta_n$.

(Fraction of type i in the mixture = $\beta'_i = \frac{\beta_i}{\sum \beta_i}$; $\sum \beta'_i = 1$).

Let the price of type i be x_i per measure (volume or weight).

Let the total amount of the mixture = A (volume or weight).

\therefore Total price = $\sum (A \beta'_i) x_i = \frac{A \sum x_i \beta_i}{\sum \beta_i}$ = Mixed Sum = X .

I do not want have to do it here then the other kinds of mixtured problems so, let the relative proportional of type I in the mixture is betai. You see **so, re** suppose the various n items are there and then the proportions are given not proportions. But the ratios the relative proportions are given beta1 to this thing so, they are not normally the total will not adapt to one. So, what you have to do is the relative fraction of type i in the mixture is you have to divide the particular quantity divided by the whole thing.

So, the sum of this fraction is equal to one but we do not need this see this will make the you know method of solution somewhat number we do not work with the slowly. So, suppose the

total price is given that is x so, that is given by total amount of mixture is a. So, then total price will be this mixture sum is this.

(Refer Slide Time: 35:12)

Formal solution

As the amount of item i in the mixture is $A\beta_i'$, and x_i is the price per measure.

$$\therefore A = \frac{X \sum \beta_i}{\sum x_i \beta_i}$$

$$\therefore \text{Amount (Measure) of type } i = \beta_i' A = \frac{\beta_i X}{\sum x_i \beta_i} = \frac{\text{Portion} \times \text{Mixed sum}}{\text{Sum of quotients}}$$

(as $\beta_i = \beta_i' \sum \beta_i$)

$$\text{Price of item of type } i = \frac{x_i \beta_i \times X}{\sum x_i \beta_i} = \frac{(\text{Price of } i) \times \text{Portion} \times \text{Mixed Sum}}{\text{Sum of quotients}}$$

And the amount of item in the mixture is a beta prime i and xi is the price so, these the solution you know you have to multiplied by this proportional factor corresponding to i. Then divided by some of quotients then whatever you x is giving getting this is which is the stated result And that is the amount of measure of type I and price also of that you can give

(Refer Slide Time: 35:42)

Mixed quantities: Example

Example in Verse 98.

कर्पूरस्य वरस्य निष्कयुगलेनैकं पलं प्राप्यते
 वैश्यानन्दनचन्दनस्य च पलं द्रम्माष्टभागेन चेत्।
 अष्टांशेन तथाऽगरोः पलदलं निष्केण मे देहि तान्
 भागैरेककषोडशाष्टकमितैर्धूपं चिकीर्षाम्यहम् ॥ ९८ ॥

"If a pala of best camphor may be had for two *nisk*'s (=32 *drammas*) and a *pala* of sandalwood for the eighth part of a *dramma* and half a *pala* of alae wood also for eighth of a *dramma*, good merchant, give me the value for one *niska* (=16 *drammas*) in the proportions of 1, 16, and 8, for I wish to prepare a perfume."

If you go through this that thing very difficult only you have to follow this and the understand the some small simplifications is making. So, if you tell an what an example it will be clearer to

you (FL) if a pala some measure okay best camphor may be had for two niskas they are some units one niska is suppose to be some 16 drammis. So, and a palas sandal wood I sfor a 8 part of a drama and half a pala of from alae wood it calls it also for 8 of a drammas that is the transalction niska (FL) and okay.

(FL) that also for a eighth of a drama, good merchant give the value of one nika a 16 drammis but they must be what is specify they must be what is specified is these must been the proportion 16 and 8 okay. So, the proportions of these things in the you know volume or weight that is given and then the relative prices are given. And what is the amount you are paid so, the total thing that is given then you have to give the quantities of those thing which are actually used to perform the

(Refer Slide Time: 37:25)

Solution

Here proportion:	(1)	(2)	(3)	
	Camphor:	Sandalwood:	Alaewood	= 1 : 16 : 8
Prices:	32	$1\frac{1}{8}$	$\frac{1}{4}$	
	(x_1)	(x_2)	(x_3)	

$$\sum x_i \beta_i = 32 \times 1 + \frac{1}{8} \times 16 + \frac{1}{4} \times 8 = 36.$$

Total price = Mixed amount = 16 drammis = X = 16.

$$\text{Quotient, } q = \frac{\text{Mixed sum}}{\text{Sum of quotients}} = \frac{X}{\sum x_i \beta_i} = \frac{16}{36} = \frac{4}{9}.$$

Amounts of item $i = \frac{\beta_i X}{\sum x_i \beta_i} = \beta_i \frac{4}{9}$. Price = $x_i \frac{\beta_i X}{\sum x_i \beta_i} = x_i \times \text{Amount}$.

\therefore Amount of Camphor: $1 \times \frac{4}{9}$, Sandalwood = $16 \times \frac{4}{9} = \frac{64}{9}$, Alaewood = $8 \times \frac{4}{9} = \frac{32}{9}$

Prices : Camphor: $32 \times \frac{4}{9} = \frac{128}{9}$, Sandal: $\frac{1}{8} \times \frac{64}{9} = \frac{8}{9}$, Alaewood: = $\frac{1}{4} \times \frac{32}{9} = \frac{8}{9}$.

Merchants, trading. Alligation: Mixture of gold of different quantities.

To prepare the perfume so, you saying camphor is you know suppose you called this 1, 2, 3 so, these are the relative prices and this on the proportions are 1:16:8 and the prices are 32 and 1 and 18 and ¼ I am sorry these not 1 1 should not be there it is only 1/8 so, the price of sandal wood is 1/8 only one should not be there 1/8 and ¼. So, the total you see see suppose your quantities are is so, 32 into 1 he amounts of prices are this 32 excess are the price this.

And these are the proportions so, you can keep it like that you do not have to normalize it I do not know make it convert into fractions. So, this is the total price so, the total price will be mixed

amount I mean the if exercise the thing and the total price is given to be 16 sorry this is a quantity the total quantity is there whatever the intermediate quantity which come that is 36 here 36. The total price I s16 the quotient is x/this thing whatever is the mixed sum that is16 the mass.

So, this divided by this so, you get 4/9 so, amounts of item will be you know various proportions are given. So, 4/9 into this whatever is given here and then you compute this individually. So, the amounts are 1 into 4/9, 16 into 4/9, and 32/9 okay. So, that has the proportion 1:16:8 and a prices of course are you know you have to multiply by the prices for 1 unit kind of a thing 1 amount. So, you have to so, just a matter small details the nothing more significant, but it is useful simplification that is what it is important.

So, similarly he talks about the various stating kind of a situation then mixtures of gold gova different quantities.

(Refer Slide Time: 45)

Section six on combinations

Verse 130-132.

एकादोकोत्तराङ्का व्यस्ता भाज्याः पृथक्स्थितैः।
परः पूर्वेण संगुण्य तत्परस्तेन तेन च ॥ १३० ॥
एकद्वित्रयादिभेदाः स्युः इदं साधारणं स्मृतम्।
छन्दश्चित्युत्तरे छन्दस्युपयोगोऽस्य तद्विदाम् ॥ १३१ ॥
मृषावहनभेदादौ खण्डमेरौ च शिल्पके।
वैद्यके रसभेदीये तन्नोक्तं विस्तृतेर्भयात् ॥ १३२ ॥

"Let the figures of one upwards, differing by one, put in the inverse order, be divided by the same (arithmetical sequence) in direct order; and let the subsequent be multiplied by the preceding, and the next following by the foregoing (result). The several results are the changes, ones, twos, threes, etc. This is termed a general rule."

So, called eligation and so on so, next he comes to the combinations so, is the very very important topic but here of course you will not giving detail one one result only basically he is stating later on he will take it up in more detail over it is fermentations and combinas since in the later part of the text. But 4o I stelling here stating here is you know (FL) let the figures of one upwards differing by one putting the inverse order be divided by the same arithmeticals in direct order.

And let the subsequent be multiplied by the preceding and the next following by the foregoing result, the several results are changes, ones, twos, threes etc., this termed general rule and then you know u have to taught of the applications of this (FL) and so on it was in (FL) for those verse there in to find the variations of meter in the (FL) as in architecture.

(Refer Slide Time: 41:24)

Combinations

It serves in prosody, for those versed therein, to find the variations of metre; in the arts (as in architecture) to compute the changes upon apertures (of a building); and (in music) the scheme of musical permutations; in medicine, the combinations of different savours. For fear of prolixity, this is not (fully) set forth."

$$\frac{n}{1} \cdot \frac{n \cdot (n-1)}{1 \cdot 2} \cdots \frac{n(n-1)(n-2)(n-r) \dots (n-r+1)}{1 \cdot 2 \cdot 3 \cdots r} = \frac{n!}{r!(n-r)!}$$

Out of n: 1 at a time: 2 at a time: 3 at a time, ... , r at a time.

Then to compute the changes upon apertures of a building in music the scheme of musical permutations in medicine the combinations of different savours and for fear of prolixity this is not fülle set forth I mean for fear of you know talking too much about this you know. So, what is stating is the (FL) etc., so what he is saying is take you know to give some number 1 write n/1 and the next n into n-1/1 into 2 etc., etc., n into n-1 up to if there odd terms you go to n-r+1.

So, that in the numerator in the denominator 1 into 2 into 3 r okay. So, what these are the things you know, so out of n you can take 1 at a time 2 at a time and r at a time these are the quantities, these are the combinations right which we have already learnt, so in modern notation it is factorial n/factorial r into factorial n-r, so is state this result.

(Refer Slide Time: 42:29)

Combinations: Example

Example in Verse 134.

एकद्वित्रयादिमुषावहनमितिमहो ब्रूहि मे भूमिभर्तुः हर्म्ये
रम्येऽष्टमूषे चतुरविरचिते श्लक्ष्णशालाविशाले।
एकद्वित्रयादियुक्ता मधुरकटुकषायाम्लकक्षारतिकैः एकस्मिन्
षड्रसैः स्युर्गणक कति वद व्यञ्जने व्यक्तिभेदाः ॥

"In a pleasant, spacious and elegant edifice with eight doors, constructed by a skillful architect, as a palace for the lord of the land, tell me combinations of doors taken one, two, three, etc. Say, mathematician, how many are the combinations in one composition, with ingredients of six different tastes sweet, pungent, astringent, sour, salt and bitter, taking them by ones, twos, threes etc."

8 7 6 5 4 3 2 1

1 2 3 4 5 6 7 8

And immediately gives an example it was 2 examples contained in this verse (FL) so in a pleasant spacious and elegant edifice with 8 doors constructed by the skillful architect as a palace for the lord of the land tell me the combinations of apperture 1, 2, 3 etc... so, these one problem then say mathematician how many are the combinations in one composition with ingredients of six different tastes sweet, pungent astringent, sour, salt and bitter, taking them by ones, twos, threes etc...

So, the once the first problem is you know thus the building with 8 windows so, what are the ways number of ways of you know opening one window then two windows. I mean two out of the 8 then 3 out of the 8 and so on so, that is one problem. Then next is you know six kinds of tastes so, sweet, pungent, astringent etc... Madura (FL) amla ect. So, taking 1, 2, 3 etc... so, remember that is one of the very ancient example right so, this was the mentioned earlier you know regarding how many tastes are there in books and related to ayurveda.

(Refer Slide Time: 44:22)

Example contd.

No. of ways: 1 at a time = $\frac{8}{1} = 8$, 2 at a time = $\frac{8 \times 7}{1 \times 2} = 28$, 3 at a time
= $\frac{8 \times 7 \times 6}{1 \times 2 \times 3} = 56$, 4 at a time = $\frac{8 \times 7 \times 6 \times 5}{1 \times 2 \times 3 \times 4} = 70$. 5 at a time
= $\frac{8 \times 7 \times 6 \times 5 \times 4}{1 \times 2 \times 3 \times 4 \times 5} = 56$, 6 at a time = $\frac{8 \times 7 \times 6 \times 5 \times 4 \times 3}{1 \times 2 \times 3 \times 4 \times 5 \times 6} = 28$, 7 at a time
= $\frac{8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2}{1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7} = 8$, 8 at a time = $\frac{8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1}{1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8} = 1$.

Total no. of variations = $2^8 - 1 = 255$.

Combinations of 6 different tastes:

6 5 4 3 2 1
1 2 3 4 5 6

No. of different types of compositions: 6, 15, 20, 15, 6, 1. Total
= $2^6 - 1 = 63$.

Chapter 5. Progressions.

Standard results on $\sum r$, $\sum r^2$, $\sum \frac{r(r+1)}{2}$, $\sum r^3$, etc., Arithmetic and Geometric Progressions.

21

So, then number of ways if you take the first example so, 1 at a time is 8/1, 2 at a time is $8 \times 7 / 1 \times 2$ etc... 3 at a time is this so, these has been done earlier. So, I will not need not going to the detail but this are the simply put it is this and the total number of variations 2 to 8 to the power of 8-1 right. So, that is the total number of combinations so, adding all of them together 1 at a time, 2 at a time etc... 8 at a time for this particular example.

Similarly for this taste so, 1 at a time it is 6, 2 at a time is 15, 3 is 20 so like that total will be 2 to the power of 6 -1 that is 63. So, next the so, this is the and other I told you you will discuss about this combinations and all that and some more advanced results in later in the text. So, I will discuss that in my last lecture on Lilavati so, then progressions so, standard results and we already know how to sum of the first ten integer sum of the squares of the first ten integers.

Then some of sums then sum of cubes and all that right so, there been dealt with in great detail I do not have to repeat them.

(Refer Slide Time: 45:42)

Number of verses with a fixed number of syllables

Verse 130-131:

पादाङ्गरमितगच्छे गुणवर्गफलं चये द्विगुणे।
समवृत्तानां सङ्ख्या तद्वर्गो वर्गवर्गश्च।
स्वस्वपदोनौ स्यातां अर्धसमानां च विषमाणाम् ॥ १३०, १३१
॥

"The number of syllables in a verse being taken for the period, and the increase twofold, the produce of multiplication and squaring (as above directed) will be the number of (variations) of like verses. Its square and square's square, less their respective roots, will be (the variations of) alternately similar and of dissimilar verses."

This rule refers specifically to the example in Verse 132.

So, then chandas example number of verses with a fixed number of syllables so, this also has been told many times (FL) okay. The number of syllables in a verse being taken for the period and the increase twofold the produce of multiplication and squaring (as above directed) will be the number of (variations) of like verses. It is square and square is square, less their respective roots, will be (the variations of) alternately similar and of dissimilar verses.

So, in fact he is actually planning to explain the I mean explain the methods for the example which comes in the next verse.

(Refer Slide Time: 46:33)

Example

Example 132.

समानामर्धतुल्यानां विषमाणां पृथक् पृथक्।
वृत्तानां वद मे सङ्ख्यां अनुष्टुप्छन्दसि द्रुतम् ॥ १४० ॥

"Tell me directly the number (of varieties) of like, alternating-like, and dissimilar Verses respectively in the metre named *anustup*."

4 <i>caranās</i>	[x x x x x x x x	8 Syllables	Total 32 Syllables.
		x x x x x x x x	8	
		x x x x x x x x	8	
		x x x x x x x x	8	

► Variations of like Verses. (All the *caranās* are alike.)
= $2^8 = 256$.

So, he saying tell me directly the number of varieties of like or alternative like and this similar verses respectively in the metre named anustup okay. So, there are 4 caranas as already has been this things so, you let it like this things at 8 syllables each. So, each of them can be (FL) right so, so which (FL) uniformly like by everybody so, I am sure you noted already detail and you know keeping it in the back of your mind.

So, these 8 syllables, 8 distincts so, total of 32 syllables all there okay suppose all the this thing caranas or (FL) they are identical. Then clearly of course each of them individually in each of them can be you know two factor of two right two kinds of things are (FL) for each of these syllable. So, 2 to the power of 8 but no more counting because all these things are repetitions are the same thing. So, 2 to the power of 8 is equal to 256.

(Refer Slide Time: 47:36)

Example

- ▶ Alternatively, alike *caranas*. To find the number of these, we find the number of varieties of the syllables in two *caranas* = $2^{16} = 65536$. If we place each one of these under itself, we get all the cases included in "alternatively like". But of these, the number of cases of "all like" are also included. Therefore number of cases of "only alternatively like" = $2^{16} - 2^8 = 65536 - 256 = 65280$.
- ▶ Total no. of variations = 2^{32} . Subtracting the case of "all like" and "alternatively like", Number of dissimilar Verses = $2^{32} - 2^{16}$. Note that the "dissimilar" only means it excludes "all like" and "alternatively like" and does not mean that all the *caranas* are dissimilar. For instance, it includes cases in which "first two *caranas* are alike, as also last two, etc."

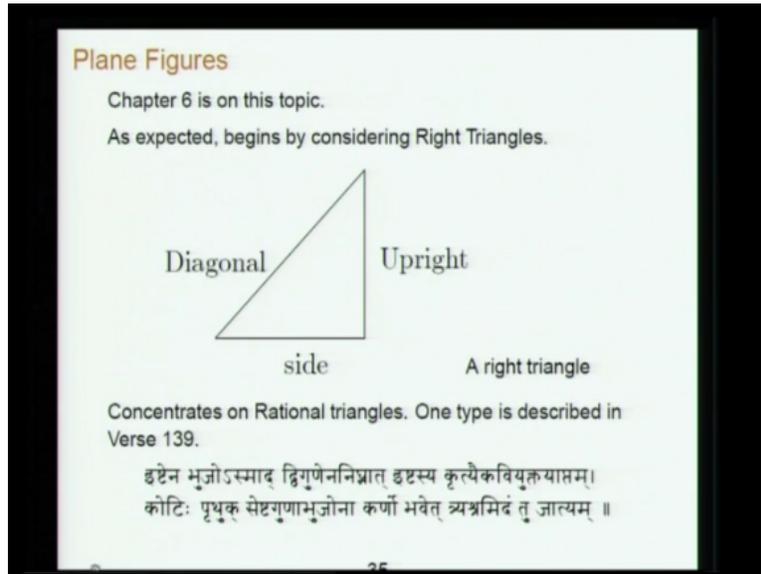

So, then alternatively alike caranas so, that is 2 to the power of 16-2 to the power of 8 so, this also has been discussed (FL) here, So, you will not showing to that so, that is the so, what you do is you know you take 2 caranas 2 caranas okay. So, one take this thing 2 caranas and then put the exactly the same thing below. So, then first and third will be alike and second and fourth will be alike okay.

So, then the number of this thing will be 2 to the power of 16 but it including the all alike also in this that also comes it have to subtract this. So, 2 to the power of 16-2 to the power of 8 and a

total number of variations is 2 to the power of 32 obviously. If all of them are you know can be arbitrary each of them is logo or guru and that is not known which of them. So, then 2 to the power of 32 will be there because so, 32 is the total number of syllables.

So, then but these things these two cases the sum will be two to the power of 16. So, subtracting the case of all like and alternatively alike number of dissimilar verses is 2 to the power of 32-2 to the power of 16. So, here dissimilar only means it took all like alternatively like and does not mean that all caranas are dissimilar no. For instance it includes case such in which first two caranas are alike as also last two and so on okay only thing is excluding all identical and alternatively identical.

(Refer Slide Time: 49:12)

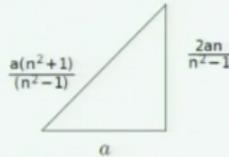

The rest of the things are that is how it is post oakly so, then (FL) right angle triangle so, he expectedly he begins been considering right triangles. So, side, upright and diagonal see concentrates and rational triangles so, one type is discussed in verse 139.

(Refer Slide Time: 49:31)

A Rational right triangle

"A side is put. From this multiplied by twice some assumed number, and divided by one less than the square of the assumed number, the upright is obtained. This, being set apart, is multiplied by the arbitrary number, and the side as put is subtracted; the remainder will be the hypotenuse. Such a triangle is termed right-angled."

It is stated that side = a , upright = $\frac{2an}{n^2 - 1}$ yields a right triangle with hypotenuse = $\frac{2an}{n^2 - 1} \times n - a = \frac{a(n^2 + 1)}{n^2 - 1}$.

(FL) A side is put from this multiplied by that is a these arbitrary from this multiplied by twice some assumed number and divided by one less than the square of the assumed number, the upright is obtained. So, this is a so, then you are you know multiplying by twice some number $2a$ so, a into $2n$ and divide by the square of that number-1 n square-1. This being set apart is multiplied by the arbitrary number and the side as put is subtracted.

The remainder will be the hypotenuse so, the in fact hypotenuse will be this so, what is saying is this you take and then multiplied by arbitrary number. And then subtract the side that what he saying so, finally you get this so, a and then this so, these are right angle triangle. So, a is rational and n is an integer so, the rational right angle triangle.

Explanation by Sūryadāsa in his commentary

Consider two triangles. The first triangle has side = $n^2 - 1$, upright = $2n$ and diagonal $n^2 + 1$. Correct as $(n^2 + 1)^2 = (n^2 - 1)^2 + (2n)^2$. Let the second triangle be similar to the above, with side = a .

(a) (b)

Similar right triangles

The upright of the second triangle = $\frac{a}{n^2 - 1} \times 2n$.

Now, hypotenuse of the first triangle
 = upright \times n - side = $2n \times n - (n^2 - 1) = n^2 + 1$.

Then, hypotenuse of the second triangle
 = Upright \times n - side = $\frac{2an}{n^2 - 1} \times n - a = \frac{a(n^2 + 1)}{n^2 - 1}$.

So, the explanation is interesting so, two triangle the first triangle as side $n^2 - 1$ $2n$ and $n^2 + 1$ suppose is the standard thing which you are discussed already right. Because these the standard right angle triangle because these whole square $n^2 - 1$ square, 1 square $+ 2n$ square is equal to $n^2 + 1$ square. So, now from this you have to get this a into this and then this is the upright and what is the diagonal of course one ways to just a proportion.

You can actually get it but his explanation is slightly interesting you know because it will be useful later on the upright is the second right triangle is this. Now hypotenuse the first rectangle you could take it as upright into n -side so, this into this-this you can view it like that. So, $n^2 + 1$ and hypotenuse the second triangle also is construct like that upright into n -side. Because there proportional you know so, the way in which you construct the hypotenuse the first triangle.

You construct a hypotenuse of the second triangle also that is what he saying and you get this so, this will be a into $n^2 + 1/n^2 - 1$.
