Properties of length function

■ **Property (4):**
Let $I \in \mathcal{I}$ be a finite interval such that
 $I \subseteq \bigcup_{i=1}^n I_i$, where each $I_i \in \mathcal{I}$, then

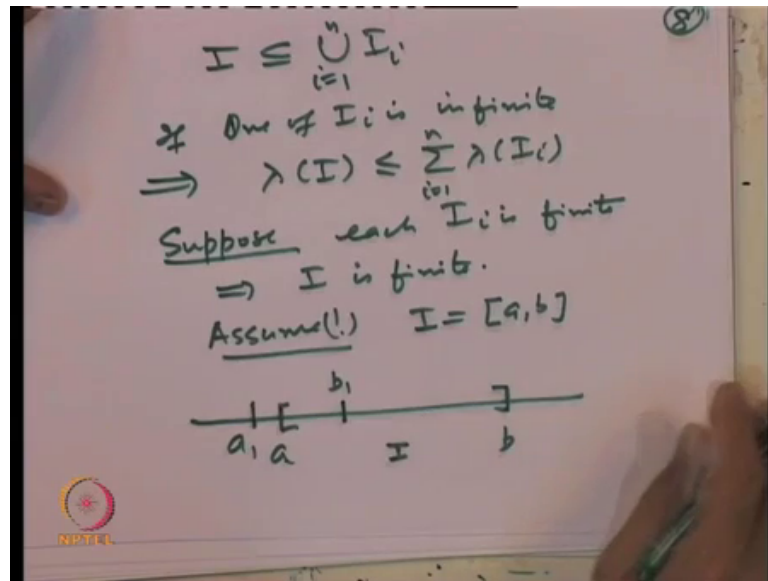

$$\lambda(I) \leq \sum_{i=1}^n \lambda(I_i).$$

NPTEL

Next let us look at another property. Supposing I is a finite interval such that I is contained in union 1 to n , I_i 's where a finite union of the intervals, but we are not longer saying that they are disjoint. Then the claim is that length of I must be less than or equal to summation length of this intervals a_i 's. So, if you drop the condition that these are pairwise disjoint I is a subset of. So, we are saying if a interval I is covered by a finite union of intervals then the length of I must be equal less than or equal to summation of length of this intervals I_i 's. Let us look at a proof of this the proof of this is once again similar to the earlier property.

(Refer Slide Time: 01:09)

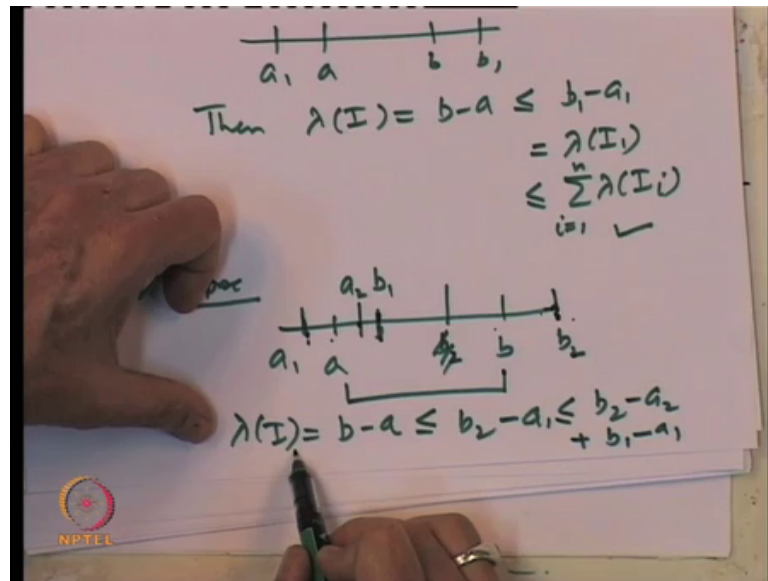

So, let us say I we are saying I is contained in union of I_i 's, I equal to 1 to n ; obviously, if one of I_i is infinite, then clearly this implies length of I is less than or equal to summation length of I_i 's that is obvious because one of this one of these terms on the right hand side in the summation is plus infinity, which is always greater than or equal to length of I whatever be i .

So, let us suppose. So, let us suppose that each I_i is finite and this is a finite union. So, that implies I is finite. So, without as before without loss of generality assume without any loss of generality that I is equal to a, b . So, here is once again the same picture here is a and here is b . Now the point a belongs to the interval i . So, this is my interval i . So, a belongs to i ; that means, it belongs to this union. So, it will belong to at least one of the intervals I_i 's let us name any one of them, which contains the point a to be I_1 and let us say the end points of that is a_1, b_1 . So, the point a belongs to one of the intervals I_i 's because it is in the union.

So, it will belong to one of them say I_1 and let us say the end points of I_1 are a_1, b_1 . So, here is the end point a_1 here is the end point b_1 now the possibility is this b_1 is on the right side of b right. So, one possibility is it is the right side of b .

(Refer Slide Time: 03:29).

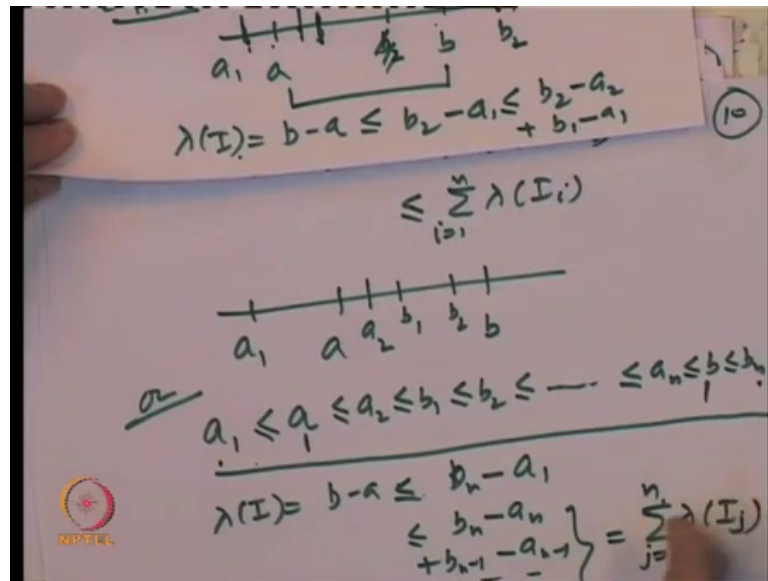

So, either. So, let us as write either b_1 is bigger than or equal to b ; that means, my picture looks like here is a_1 here is a here is b and here is b_1 then length of I which is equal to b minus a is less than or equal to b_1 minus a_1 which is equal to length of I_1 and which is; obviously, less than or equal to summation length of I_i 's I equal to 1 to n .

So, in the case b_1 is on the right side where; obviously, through by this case. So, what is the another possibility case 2. So, suppose this is the picture. So, suppose this is the picture namely we have got a we have got b and here is a_1 and b_1 is on the not on the right side, but on the left side of a b . So, let us take that as the picture. So, in that case the point b_1 belongs to that union. So, b_1 is in the interval a b . So, it will belong to that union. So, it belongs. So, b_1 belongs to y . So, it belongs to union. So, it will belong to one of the intervals in the I_i 's. So, let us call that has some interval I_2 .

So, b_1 belongs to I_2 so; that means, a_2 must start here and b_2 either it will be somewhere here or it will be on the right side. So, and if it is on the right side of it; that means, what. So, let us say I is on the right side. So, here is b_2 instead of here let us say b_2 is here then the length of the interval i . So, length of the interval, I which is equal to b minus a this is b minus a this is less than or equal to b_2 minus a_1 b_2 minus a_1 which is less than or equal to b_2 minus a_2 plus b_1 minus a_1 . So, b_2 minus a_1 is less than or equal to b_2 minus a_2 plus b_1 we are adding something bigger and then a_1 .

So, that is length of i .

(Refer Slide Time: 06:08)

So, in that case length of I will be less than or equal to length of I_1 plus length of I_2 and so that is any way less than or equal summation length of I_i 's, I equal to 1 to n . So, if you go on repeating this process. So, what does it mean? So, in the next stage, what is another possibility that b_1 is inside so; that means, here is here is a here is b , if it is not outside that must be inside; that means, there is a 1 here is here was our b_1 here is a 2 and somewhere here is b_2 it is not on the right side you will the left side. So, once again b_2 belongs and then we can proceed in the same way. So, either at some stage will be through or eventually f naught then we will have a_1 is less than equal to a is less than or equal to a_2 less the or equal to b_1 less than or equal to b_2 less than or equal to. So, on less than or equal to a_n less than or equal to b less than or equal to b_n .

So, what we are saying is either will be through at some finite stage or we can rearrange eventually after end stage is the end points in that way in that case again $\lambda(I)$ which is equal to b minus a . So, here is a here is b is less than or equal to same idea b_n minus less than or equal to b_n minus a_1 . So, go on adding and subtracting less than equal to b_n minus a_n plus b_n minus 1 minus a_n minus 1 and soon and plus b_1 minus a_1 and that is equal to $\sum_{j=1}^n \lambda(I_j)$. So, it is just whenever we were infinite stage the end points can be rearrange nicely and we get the property namely the length function is having the property whenever a interval I is covered by a finite union of intervals then the length of I is less than or equal to summation length of I_j 's.

(Refer Slide Time: 08:22).

Properties of length function

- **Property (4):**
Let $I \in \mathcal{I}$ be a finite interval such that $I \subseteq \bigcup_{i=1}^n I_i$, where each $I_i \in \mathcal{I}$, then
$$\lambda(I) \leq \sum_{i=1}^n \lambda(I_i).$$
- **Property (5):**
Let $I \in \mathcal{I}$ be a finite interval such that $I \subseteq \bigcup_{i=1}^{\infty} I_i$, where each $I_i \in \mathcal{I}$, then
$$\lambda(I) \leq \sum_{i=1}^{\infty} \lambda(I_i).$$

NPTEL

Let us look at the an extension of this property namely exposing I is a finite interval such that I is covered by a union of intervals I_i 's 1 to infinity; that means, the interval I is covered by union of a countable union of intervals I_i 's then again the claim is length of I is less than or equal to summation length of I_i 's. So, let us prove this property and keep in mind here we are assuming our interval I is a finite interval.

(Refer Slide Time: 09:11)

$$I \subseteq \bigcup_{i=1}^{\infty} I_i, \quad I \text{ finite} \quad (ii)$$
$$\Rightarrow \lambda(I) \leq \sum_{i=1}^{\infty} \lambda(I_i) !$$

Note if I_i is infinite for some i ,
then $\lambda(I_i) = +\infty$
 $\geq \lambda(I)$
$$\Rightarrow \sum_{j=1}^{\infty} \lambda(I_j) \geq \lambda(I)$$

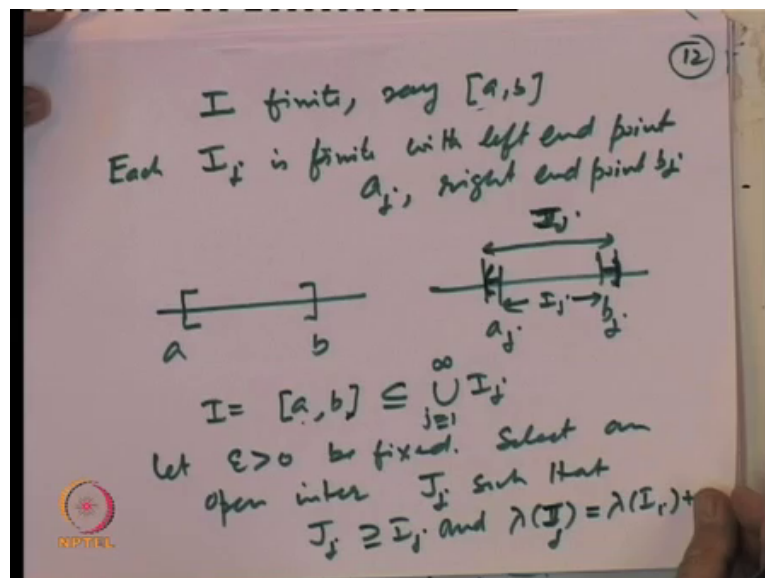

✓

NPTEL

So, interval I is contained in union of intervals I_i 's I equal to 1 to infinity these are intervals I finite this implies length of I is less than or equal to summation length of I_i 's, I equal to 1 to infinity this is what we want to prove.

Obvious guess note, if any one of the terms on this side lambda of I_i 's is infinite then, we are through. So, that is note if I_i is infinite for some i then what will happen length of I_i will be equal to plus infinity which is bigger than or equal to length of I , whatever it may be weather finite or infinite. So, that is. So, implies sigma length of I_j j equal to 1 to infinity is also bigger than or equal to lambda of because one of them is infinite. So, that case is obvious. So, let us assume not only I is finite all the intervals I_i 's are also finite and we want to check this property. So, what we want to check is the following.

(Refer Slide Time: 10:36)

I finite say end points say a b we can assume it is a closed interval because the length of I is not going to change each I_j is finite, with left end point a_j right end point b_j .

We are not saying that we are assuming this I_j 's are open or close or anything we are just naming the end points the left endpoint of I_j . So, we are saying I looks like an a and b and each I_j is a_j , b_j we are not saying that this end points are included and we are given that I which is a b is contained in union of I_j I equal to 1 to infinity right. And if this was finite there will be already know how to manipulate that that we have already done earlier in the previous case. So, the idea is from that infinite union brings it to a finite

union and here is closed bounded interval contained in a infinite union and you want to say this is going to be contained in a finite union.

So, somewhere the compactness property of the interval a to b is going to be used so, but for that we need the intervals to be open. So, let us make this intervals ideas open, but of course, the lengths will change. So, let us let us fix let epsilon greater than 0 b fix select an open interval say call it is J_j , such that this J_j includes the our interval I_j and does not change the length much. So, length of I length of this J_j is equal to say length of I_j plus epsilon. So, slightly increase. So, what were saying in this picture take a interval from here to here the open interval from here to here call that as J_j of J . So, each I_j I_j which was some a_j to here b_j is enclosed in an open interval slightly bigger, but the length. So, this is the length portion that you had that at the most is equal to epsilon.

So, now what happens is the following.

(Refer Slide Time: 13:50)

$$[a, b] \subseteq \bigcup_{j=1}^{\infty} I_j \subseteq \bigcup_{j=1}^{\infty} J_j$$

Heine Borel Property $\Rightarrow \exists n \text{ s.t.}$

$$I = [a, b] \subseteq \bigcup_{j=1}^n J_j$$

$$\Rightarrow \lambda(I) \leq \sum_{j=1}^n \lambda(J_j)$$

$$\leq \sum_{j=1}^n [\lambda(I_j) + \epsilon]$$

$$\leq \sum_{j=1}^{\infty} \lambda(I_j) + \underbrace{\sum_{j=1}^{\infty} \epsilon/2^j}_{=\epsilon}$$

let $\epsilon \rightarrow 0$

So, a, b is contained in union of I_j 's. And each I_j is contained in the union of J_j 's and each J_j is a open interval. So, we are taken a open interval. So, we have got a open cover of the closed boundary interval a, b . So, implies by Heine borel property of the real line which says whenever I closed boundary interval is covered by an collection of open intervals then the implies there exist some n such that finite number of them we will cover it. So, a, b will be contained in union of J equal to 1 to n J_j 's finite number of them

will cover it and now implies by our earlier case that length of I is less than or equal to $\sum_{j=1}^n \text{length of } I_j$. So, this was my interval I length of I is less than or equal to $\sum_{j=1}^n \text{length of } I_j$ ok.

Now, each one of them is less than or equal to $\sum_{j=1}^n \text{length of } I_j$ plus ϵ . And now we want to separate out this summation and let it go to infinity and could want to infinity, but the problem will come because of the summation ϵ added n times that summation will tend to become very large, we do not want to happen that. So, what we go is we revise our construction. So, where we selected for a given ϵ fix select and open interval I_j such that this is. So, instead of ϵ for the interval I_j let us divided by 2 to the power j . So, instead of having this extra length to be equal to same length as ϵ for everyone interval I_j for I_j we want this extra length to be equal ϵ by 2 to the power j .

So, once we do that we are in a better shape because now this as estimate will be 2 to the power j so; that means, it is less than or equal to $\sum_{j=1}^n \text{length of } I_j$ plus $\sum_{j=1}^n \epsilon / 2^j$. So, what we are saying is length of I is less than or equal to $\sum_{j=1}^n \text{length of } I_j$ plus a number ϵ , but ϵ was a arbitrary. So, let ϵ go to 0 . So, we will get length of I is less than or equal to $\sum_{j=1}^n \text{length of } I_j$. So, what we are saying is

(Refer Slide Time: 17:18)

Properties of length function

- **Property (4):**

Let $I \in \mathcal{I}$ be a finite interval such that $I \subseteq \bigcup_{i=1}^{\infty} I_i$, where each $I_i \in \mathcal{I}$, then
$$\lambda(I) \leq \sum_{i=1}^{\infty} \lambda(I_i).$$

 © 2009 A. Sankar, IIT Bombay - p. 12/18

That the countable property that way you looked that namely length of I is less than equal to summation length of I_i 's whenever a interval I which is finite is covered by any countable union then the length of I is less than or equal to length of I_i 's.

So, this is we have extended that earlier property from whenever a finite covering is there we have go extended it to a countable infinite covering, but only for finite intervals. Now we would like to extend this to even arbitrary intervals which are not necessarily finite. So, for that we will have to do a little bit more work. So, let us look at the next property.

(Refer Slide Time: 18:06)

Properties of length function

- **Property (5):** Let $I \in \mathcal{I}$ be a finite interval such that $I = \bigcup_{n=1}^{\infty} I_n$, where $I_n \in \mathcal{I}$ and $I_n \cap I_m = \emptyset$ for $n \neq m$.

Then

$$\lambda(I) = \sum_{n=1}^{\infty} \lambda(I_n).$$

NPTEL

Which says the following let, I be a finite interval such that I is equal to union 1 to infinity I_n where I_n 's are pair wise disjoint then at least we can conclude that the length of I is equal to summation length of I_n 's. So, whenever a finite interval is a countable union of pair wise disjoint intervals then the length of I is equal to summation length of I_n 's. So, let us prove this property.

(Refer Slide Time: 18:48)

$I = \bigcup_{j=1}^{\infty} I_j, I_j \cap I_k = \emptyset$ (13) (14)

I finite
 $\Rightarrow \lambda(I) = \sum_{j=1}^{\infty} \lambda(I_j)$

Note
 $\lambda(I) \leq \sum_{j=1}^{\infty} \lambda(I_j)$ — (1)

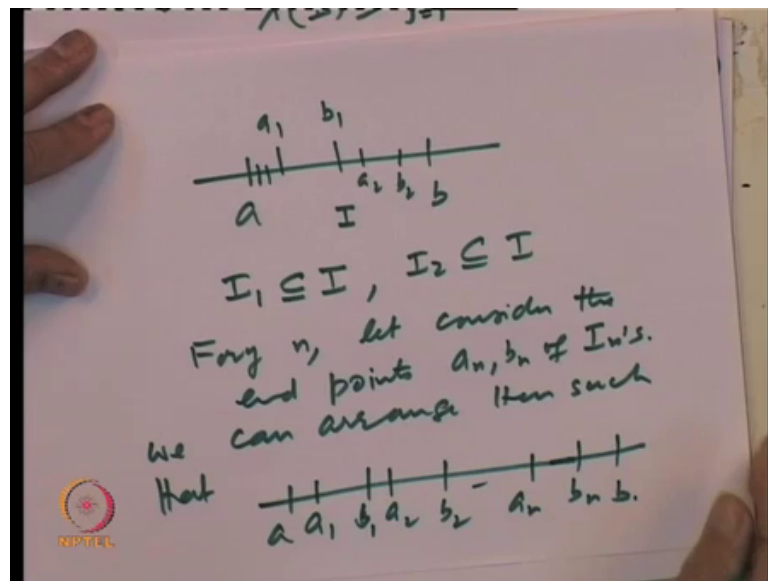

Only to show
 $\lambda(I) \geq \sum_{j=1}^{\infty} \lambda(I_j) ?$

NPTEL

So, what we got I is equal to union of I_j 's j equal to 1 to infinity I_j 's are pair wise disjoint I finite implies length of I is equal to summation length of I_j 's

So, let us observe note we have already proved just now that if a interval is written as this a union of countable disjoint union note length of i , we have just now shown is less than or equal to length of I_j 's added up j equal to 1 to infinity call it 1. So, length of I is less than or equal to this, I have just now we have proved for finite levels. So, only to show only to show that length of I is bigger than or equal to summation j equal to 1 to infinity length of I_j . So, only this is to be shown and for that. So, here is.

(Refer Slide Time: 20:08)

The interval a to b I is finite. So, there is a interval finite interval I now look at I_1 is a subset of i . So, it will be somewhere inside. So, somewhere is a_1 somewhere is b_1 .

Similarly, I_2 is also inside i . So, somewhere it has to be either it has to be a to here, b_2 here or it could be here somewhere right and soon. So, for every n let us look at let us consider the endpoints the end points a_n, b_n of I_n 's we can we can arrange we can arrange there only finitely many of them such that, here is a here is a_1 here is b_1 here is a_2 here is b_2 and soon here is a_n and here is b_n . And here is b .

(Refer Slide Time: 21:40)

Handwritten notes on a whiteboard:

$$a \leq a_1 \leq b_1 \leq a_2 \leq b_2 \leq \dots \leq a_n \leq b_n \leq b$$

$$\Rightarrow \lambda(I) = b - a$$

$$\geq b_n - a_1$$

$$\geq b_n - a_n + b_{n-1} - a_{n-1} + \dots + b_1 - a_1$$

$$= \sum_{i=1}^n \lambda(I_i)$$

that means, we can arrange them in such a way that a is less than or equal to a_1 less than or equal to b_1 which is less than or equal to a_2 less than or equal to b_2 . And so on less than or equal to a_n less than or equal to b_n and which is less than or equal to b once that is done.

So, this implies by simple algebra; that means, length of I which is equal to b minus a now this is $b - a_1$ now this is $b - a_1 + a_1 - a_n + b_n - a_n$ now this is $b - a_1 + b_n - a_n + a_n - a_{n-1} + b_{n-1} - a_{n-1}$ and so on plus $b_1 - a_1$. So, this put together is nothing, but which is equal to $\sum_{i=1}^n \lambda(I_i)$. So, what we are saying is for every end the end points of the intervals I_1, I_2, \dots, I_n we have to rearrange them in this fashion and hence by looking at the ordering of this length of I is bigger than and this happens for every end.

So, that implies length of I is bigger than or equal to $\sum_{i=1}^n \lambda(I_i)$ for every n . So, what we are saying is for every end the end points of the intervals I_1, I_2, \dots, I_n we have to rearrange them in this fashion and hence by looking at the ordering of this length of I is bigger than and this happens for every end. So, that implies length of I is bigger than or equal to $\sum_{i=1}^n \lambda(I_i)$ for every n . So, what we are saying is for every end the end points of the intervals I_1, I_2, \dots, I_n we have to rearrange them in this fashion and hence by looking at the ordering of this length of I is bigger than and this happens for every end. So, that implies length of I is bigger than or equal to $\sum_{i=1}^n \lambda(I_i)$ for every n . So, what we are saying is for every end the end points of the intervals I_1, I_2, \dots, I_n we have to rearrange them in this fashion and hence by looking at the ordering of this length of I is bigger than and this happens for every end.

Thank you.
