Lecture - 07 A
Countably Additive Set Functions on Intervals

Welcome to lecture 7 on measure and integration.

(Refer Slide Time: 00:26)

If you recall in the previous lecture we had started looking at the countable additive set functions on intervals and we proved some properties of such countably additive set functions. We will recall that the theorem that we were proving and then continue the proof and if time permits we look at a characterizations of a countably additive set functions defined on algebras in the later part of the lecture. So, let us just recall what we are proving in the last lecture.

(Refer Slide Time: 00:54)

Countably additive set functions on intervals

- Let $\mu : \tilde{\mathcal{I}} \rightarrow [0, \infty]$ be a finitely additive set function such that $\mu(a, b) < +\infty$ for every $a, b \in \mathbb{R}$.
- Then there exists a monotonically increasing function $F : \mathbb{R} \rightarrow \mathbb{R}$ such that
$$\mu(a, b) = F(b) - F(a) \quad \forall a, b \in \mathbb{R}.$$

If μ is also countably additive, then F can be selected to be right-continuous.

©2009, Prof. J. K. P. S. 1/10

We were trying to show that if μ is a finitely additive set function defined on the collection of all left open right closed intervals which was denoted by $\tilde{\mathcal{I}}$, if such a finitely additive set function is given with a property that μ of any finite interval is finite. So, μ of left open right close interval a, B is finite for every A and B then we wanted to characterize such countable additive properties of such functions and related to a class of functions on the real line.

So, the claim of the theorem is that then there exist a monotonically increasing function F from \mathbb{R} to \mathbb{R} such that the value μ of the open left open right closed interval a, B is given by $F(B) - F(a)$ for every A and B belonging to \mathbb{R} . So, we want to show that given a we wanted to show that given a finitely additive set function on the class of all left open right close intervals it must arise from a monotonically increasing right continuous function f , with the relation that the value μ of a, B is given by the difference $F(B) - F(a)$. And in addition if μ is here μ also only finitely additive if we assume μ is countably additive then F this function F can be selected to be right continuous.

(Refer Slide Time: 02:40)

Countably additive set functions on intervals

- Define F as follows:

$$F(x) := \begin{cases} \mu(0, x] & \text{if } x > 0, \\ 0 & \text{if } x = 0, \\ -\mu(x, 0] & \text{if } x < 0. \end{cases}$$

- We proved: F is monotonically increasing.
- We were proving: if μ is also countably additive, then F is right continuous at every $x \in \mathbb{R}$.

So, let us recall how if we define this function we looked at the function F defined by F at a point x is defined as the measure μ of the interval 0 to x if x is bigger than 0 , and it is 0 if x is equal to 0 and is minus μ of x to 0 closed at 0 if x is less than 0 .

So, this was the definition of the function F and we proved the property that this function F indeed is monotonically increasing. And for that if you recall we use the fact that F the measure μ this μ is a countable is a finitely additive set function. So, in next we if you assume that μ is countably additive we wanted to show that this function F is right continuous at every point x in \mathbb{R} .

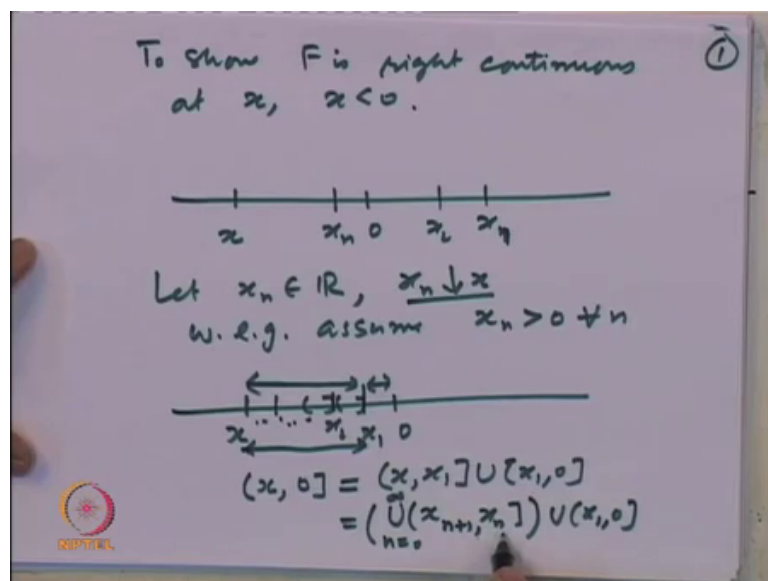

(Refer Slide Time: 03:43)

And we had started looking at the proof even x is bigger than or equal to 0. So, we had proved that for x bigger any point x bigger than or equal to 0 F is right continuous at the point x is equal to 0. So, let today we will start with proving the other part remaining part of the proof namely if x is less than 0 then also F is right continuous at x .

So, let us look at the proof.

(Refer Slide Time: 04:08)

So, we want to show F is right continuous at a point x where x is less than 0. So, here is the point 0 and here is x . So, to show right continuity at the point x let us take. So, let x_n

belong to \mathbb{R} . So, let us points x_n a sequence in \mathbb{R} say that x_n decrease is to x ; that means, x_n is converging all the x_n s are on the right side of the x and is converging to x . So, because it all the points x_n s are on the right side of. So, here may be $x_n > x-1$ here may be $x-2$. So, on. So, after some stage x_n has to cross over the point 0 the value 0. So, what we are saying is without loss of generality assume that all the x_n s are bigger than 0 for every n because x_n is going to converge to x and x is less than 0.

So, at some stage it has to cross over. So, analyzing we can start analyzing the sequence from that point onwards or one writes this has without loss of generality the proof is not change if you assume x_n is less than 0 for n . So, here is the situation here is the point x here is the point 0 and here is the point $x-1$. So, now, let us look at. So, here is $x-2$ and so on. So, let us observe that the interval left open right close 0 can be written as $(x-2, x-1] \cup (x-1, 0]$. So, I can write this as from this point to $x-1$ and from this point onwards to this one. And now this interval x to $x-1$ and going to split further into a union of intervals. So, my claim is that this x to $x-1$ is same as $(x-1, x-2] \cup (x-2, x-3] \cup (x-3, x-4]$ and so on. So, we are going to claim is that this is same as $(x_{n+1}, x_n]$ left open right close union $n \rightarrow \infty$ equal to $(x, x-1]$.

So, the interval x to $x-1$ this part we are splitting it into left open right close left open right close and so on and because this is true this this is equality because x_n is decreasing to x . So, at any point here in between if i take from any point in between x and $x-1$ then that stage has to be crossed over by some x_n . So, that point will belong here. So, this the interval x to $x-1$ is a union of the intervals left upon x_{n+1} to close x_n $n \rightarrow \infty$. So, and also observe that these intervals are all disjoint. So, these are all disjoint intervals.

(Refer Slide Time: 07:53)

$$\begin{aligned}
 \text{M.C.A.} &\Rightarrow \\
 \mu(x, 0] &= \sum_{n=0}^{\infty} \mu(x_{n+1}, x_n] + \mu(x_1, 0] \\
 &= \lim_{k \rightarrow \infty} \sum_{n=0}^k \mu(x_{n+1}, x_n] + \mu(x_1, 0] \\
 -F(x) &= \lim_{k \rightarrow \infty} \left[\sum_{n=0}^k F(x_n) - F(x_{n+1}) \right] + F(x_1) \\
 &= \lim_{k \rightarrow \infty} \left[\begin{array}{l} F(x_1) - F(x_2) \\ + F(x_2) - F(x_3) \\ \vdots \\ + F(x_k) - F(x_{k+1}) \end{array} \right] + F(x_1) \\
 &= \lim_{k \rightarrow \infty} [F(x_1) - F(x_{k+1})] + F(x_1)
 \end{aligned}$$

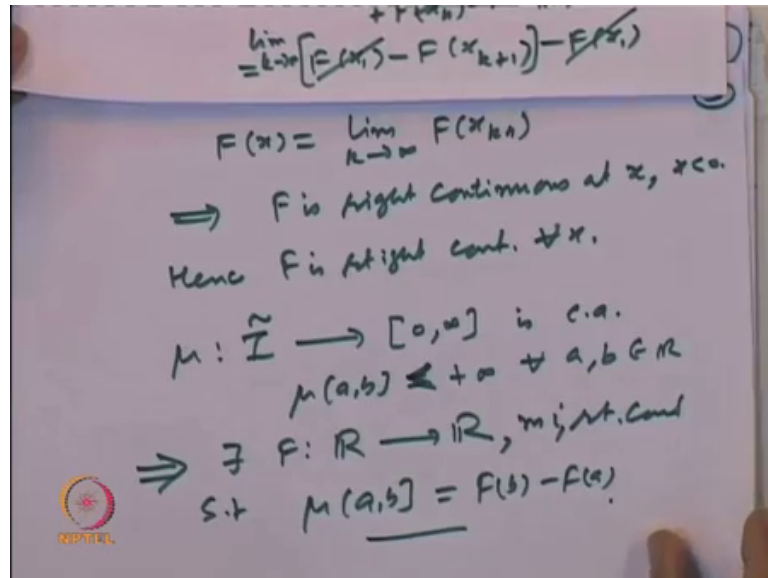

So, I can write mu of using countably additive property of the set function I can write this is equal to summation n equal to 0 to infinity mu of x n plus 1 x n plus mu of x 1 to 0. So, here we have used the fact that mu countably additive implies this property is true. And now this right inside is a sequence of a nonnegative real numbers possibly extended real numbers.

So, I can write this as limit k going to infinity sigma n equal to 0 2 k, mu of x n plus 1 x n plus mu of x 1 to 0 close here 0 . So, now, we will write everything in term of F. So, by definition mu of x to 0 is minus F of x is equal to limit k going to infinity summation n equal to 0 to k and this is nothing, but F of x n minus F of x n plus 1 plus F of F of x 1 to 0. So, that is in fact, minus F of x 1. So, now, let us x ah note what is this so this is limit k going to infinity and what is the sum this is starts with n equal to n equal to 0 will give x 0 that is not. So, let us. So, there was a well take care i should have written as union from n equal to one because it is one to 2 right one to 2 and so on. So, that was the mistake here.

So, this sum is from n equal to one to n equal to one to n equal to one to k. So, what is the sum. So, n equal to 1. So, that gives you F of x 1 minus F of x 2 plus F of x 2 minus F of x 3 and so on. Plus, F of x n equal to k. So, that is x k minus F of x k plus 1. And now so, that is this part the sum and minus F of x 1. So, now, we observe that in this x 1 x 2 x 2 this will cancel out and what is left with this is equal to F of x 1 minus F of x k

plus 1 minus F of x 1. And now in this equation so this cancels with this so minus F of x oh sorry that is the limit outside. So, limit of this k going to infinity. So, what we get is F of x is equal to. So, this gives us that F of x.

(Refer Slide Time: 11:18)

Is equal to limit k going to infinity of F of x k plus 1. And that proves the fact that F is right continuous at x in the case when x was less than 0.

So, hence F is right continuous or every x. So, this proves the theorem that if mu on the class of all left open right closed intervals is a measure is countably additive with the property that mu of a B is equal mu of a B is finite for every B in R then this is implies there is a function F which is monotonically increasing which is right continuous. So, monotonically increasing right continuous such that, mu of a B is equal to F B minus F of a. So, this is says. So, what we have shown is that to every countably additive set function mu on left open right closed intervals you can associate a monotonically increasing a right continuous function.

(Refer Slide Time: 12:59)

Countably additive set functions on intervals

- We proved it when $x \geq 0$.
To complete the proof, we prove it for $x < 0$.
- Thus, every μ is a countably additive set function $\mu : \tilde{\mathcal{I}} \rightarrow [0, \infty]$, such that $\mu(a, b] < +\infty$, for every $a, b \in \mathbb{R}$. is given by a monotonically increasing right continuous function $F : \mathbb{R} \rightarrow \mathbb{R}$ with

$$\mu(a, b] = F(b) - F(a) \quad \forall a, b \in \mathbb{R}.$$

The converse of above is also true:

NPTEL

And we will next show so, this is proved at this completes the proof of the fact that to every monotonically increasing right continuous function, we can associate a to every a countably additive set function on the class of intervals, we can associate a monotonically increasing right continuous function with this property.

In fact, the converse of the statement also holds. So, what will be the converse of such a statement. The converse of such a statement would be that if you are given a monotonically increasing right continuous function F , then we can define a way a set function μ on left open right closed intervals in such a way that this equation is satisfied the is relation is satisfied. So, that will prove that the only way monotonically only way we can construct accountably additive set functions on the class of intervals is via monotonically increasing right continuous functions.

(Refer Slide Time: 14:13)

Countably additive set functions on intervals

- Let $F : \mathbb{R} \rightarrow \mathbb{R}$ be a monotonically increasing function.

Define $\mu_F : \tilde{\mathcal{I}} \rightarrow [0, \infty]$ by: for $a, b \in \mathbb{R}$,

$$\mu_F(a, b] := F(b) - F(a),$$
$$\mu_F(-\infty, b] := \lim_{x \rightarrow \infty} [F(b) - F(-x)],$$
$$\mu_F(a, \infty) := \lim_{x \rightarrow \infty} [F(x) - F(a)],$$
$$\mu_F(-\infty, \infty) := \lim_{x \rightarrow \infty} [F(x) - F(-x)].$$

 NPTEL

© Indian Inst of Technol 2013

so the converse part of the theorem says the following let $F : \mathbb{R} \rightarrow \mathbb{R}$ be a monotonically increasing function from \mathbb{R} to \mathbb{R} . So, define μ_F a set function from on the class of all left open right closed intervals has follows, for any 2 real numbers A and B we want to define what is μ_F of the close left upon right closed intervals a, b .

So, because this is the property has to be satisfied by F . So, that itself gives us the defining property of the set function μ . So, μ_F of the left open right closed interval is defined as the difference $F(B) - F(a)$ for all real numbers a and b . And now the question comes what happens if B is equal to plus infinity or a is equal to minus infinity or both of them. So, in that case we write this as for μ_F of the infinite interval minus infinity to b . So, it is open on the left side and close on the right side b . So, it is left open right closed interval on the real line. So, it what we do is we the definition as $F(B) - F(-x)$ as x goes to infinity. So, as x goes to infinity $-x$ will go to minus infinity.

So, we are using we are defining it via limits. So, look at the interval a to x to be left open. So, that is the value of the μ of F and then take the limit of that as x goes to infinity. So, this is the definition of μ_F of minus infinity to b . And similarly if it is on the right side. So, if a to infinity. So, what we defined as take the interval a to closed x . So, then the value of that will be $F(x) - F(a)$, and now take the limit of that as x goes to infinity. So, for the infinite interval unbounded on the right side left open right

close. So, a to infinity is defined as $\lim_{x \rightarrow \infty} (F(x) - F(a))$. And if it is the whole real line then we define μ of F of the whole real line to be $\lim_{x \rightarrow \infty} (F(x) - F(-x))$. So, look at the interval $[-x, x]$ and let both sides go to infinity.

So, this is the way we define μ of F . And now note that this is a generalization of the length function if F is the identity function namely $F(x) = x$, that is a monotonically increasing function then this is nothing, but $B - a$. So, μ of a, B is $B - a$. So, this μ of F is nothing, but the length function when F is a monotonically increasing function. And one can write down a proof of this on the lines of when we proved that the length function is countably additive. So, on the same lines one can write down the proof of the fact that this set function μ of F is also countably additive. One can wonder where one will be using the fact that F is right continuous. So, the fact where will be using the right continuity of this F to prove that it is monotonically increasing to prove that μ of F is countably additive.

So, this F for a monotonically increasing we can define this μ of F is finitely additive, but to prove countably additive we need F to be a right continuous function. So, if F is right continuous then, one can write down a proof similar to that of the case of the length function. One use this fact right continuity because one has to deal with the intervals which are left open end right closed. So, we says that if you are keen to know a proof of this you better write a proof yourself and trying to see that the steps given for the proof of the length function is countable additive can be suitably modified to do this so we leaved it as a exercise and if we feel it is too tough exercise let us assume this and go ahead.

(Refer Slide Time: 19:01)

Countably additive set functions on intervals

- μ_F is a well-defined finitely additive set function on $\tilde{\mathcal{I}}$.
- If F is right continuous, then μ_F is also countably additive.
- One calls μ_F the set function induced by F .

NPTEL

So, μ_F is a finitely additive sets function and using if F is right continuous one proves that μ_F is also countably additive.

So, this gives us this is this function μ_F is called the set function induced by the increasing function F .

(Refer Slide Time: 19:20)

Countably additive set functions on intervals

- Completely characterize the non-trivial countably additive set functions on intervals in terms of functions $F : \mathbb{R} \rightarrow \mathbb{R}$ which are monotonically increasing and right continuous.
- In case $\mu(\mathbb{R}) < +\infty$, a more canonical choice for the required function F is

$$F(x) := \mu(-\infty, x], \quad x \in \mathbb{R}.$$

Such functions are called **distribution functions on \mathbb{R}** .

NPTEL

So, this gives us a complete characterizations of non trivial countably additive set functions why nontrivial because we are looking at μ of the left open right closed interval a, b to be finite. In terms of functions which are monotonically increasing and

right continuous. So, in some sense there is a correspondence between measures on the class of all intervals and monotonically increasing right continuous functions. In case that a countably additive set function μ has the property that μ of the whole real line is finite then one can select this monotonically increasing function to be μ of minus infinity to x because then this is defined.

We do not have to restrict the fact that μ of a B is finite that will be true anyway because this is finite. So, a more canonical choice for the monotonically increasing right continuous function monotonically increasing right continuous function is μ of minus infinity to x when μ of the whole space R is finite. So, in that case this function F is called the distribution function on R , and this plays a role in the theory of probability where monotonically increasing right continuous functions are studied via what are called probability distributions. We will not go into that. So, we will just make a note of it in case we have finite condition that μ of R is finite we will take μF of x to be that this function.

So, this proves the this is we have characterized all countably additive set functions on the class of all intervals. The aim what we will shall do now next is the following we will study what are called a set functions on general class of sets called algebras.

(Refer Slide Time: 21:37)

Set functions on algebras

- Let \mathcal{A} be an algebra of subsets of a set X and let $\mu : \mathcal{A} \rightarrow [0, \infty]$ be a set function. Then the following hold:
 - If μ is finitely additive and $\mu(B) < +\infty$ for $B \in \mathcal{A}$ then

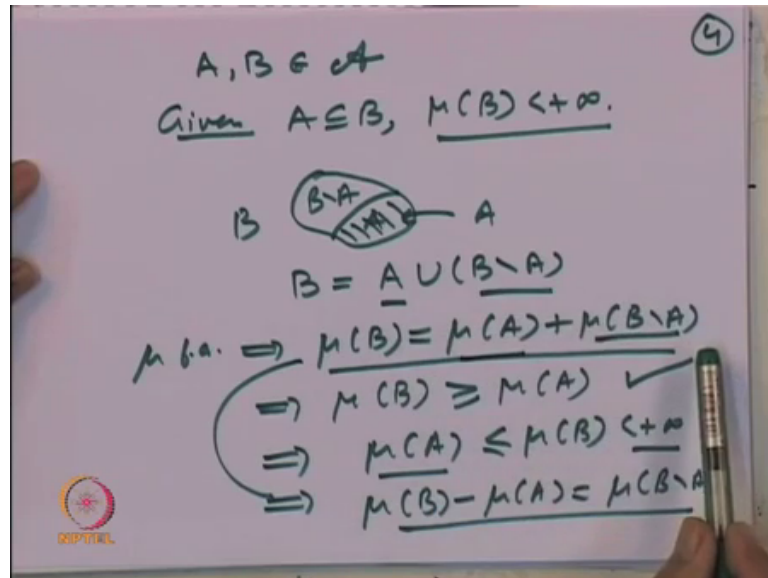

$$\mu(B - A) = \mu(B) - \mu(A)$$
 for every $A \in \mathcal{A}, A \subseteq B$.

NPTEL

Where a so, let us start with looking at a an algebra of subsets of a set x and μ a set function defined on this algebra taking a negative real valued. So, taking values in 0 to

infinity then we want to show that the following holds that if μ is finitely additive, and μ of the set B is finite for a set B in the algebra \mathcal{A} then μ of the difference B minus A is equal to $\mu(B) - \mu(A)$ whenever A is in the algebra and A is a subset of B . So, what we are saying is the following.

(Refer Slide Time: 22:21)

So, let us take two sets A and B belonging to the algebra \mathcal{A} and we are given of course, A is subset of B and μ of B is finite. So, here is the set B and A is a part of it.

So, this B . So, that is A . So, this part is A . So, we can write B as a union B minus A . So, this is the part B minus A right and note that A and B minus A both are disjoint sets. So, B is written as a finite union. In fact, union of the 2 sets A and B minus A and their pairwise disjoint μ finitely additive implies that μ of B is equal to μ of A plus μ of B minus A and now let us note that this all are real numbers μ of B is a real number because A is finite μ of A is a real number because A is a subset of B . So, that is and μ of A will be less than or equal to μ of B that is finite. So, that is so these are all this is an equation in real numbers anyway anywhere that is not really important here.

But note that all are nonnegative quantities. So, that implies that μ of B is bigger than or equal to μ of A that is one thing that we observe that because this is non negative. So, this is so this is also implies that μ of A is less than or equal to μ of B which is finite right. So, that implies μ of A is finite. So, in this equation now I can say all are

real numbers. So, I can manipulate this as equation in real numbers. So, this equation implies that if I take it on the other side. So, $\mu(B) - \mu(A)$ is equal to $\mu(B) - \mu(A)$. So, that is what we wanted to prove, and note there we have used the fact that $\mu(B)$ is finite and hence μ of every subset of it is finite whenever that set is in the algebra right. So, we can manipulate this as an equation only when they are real numbers if they are equal to plus infinity or minus plus infinity at any one of them, then I cannot transpose them on the other side and write this equation.

So, we have used the fact that μ is finitely additive and $\mu(B)$ is finite that implies for every subset A of B which is in the algebra $\mu(A)$ is also finite and $\mu(B) - \mu(A)$ is equal to $\mu(B) - \mu(A)$. And in particular suppose I take B equal to A . So, this gives $\mu(\text{empty set})$ is equal to 0. So, in particular $\mu(\text{empty set})$ is 0 if μ is finitely additive and μ for at least one set B is finite. So, these are consequences of a set function being finitely additive. So, what we are trying to show is if a set function is finitely additive what are the possible consequences we showed finite additivity implies monotone right, and if B is finite then I can interchange and right $\mu(B) - \mu(A)$ to B equal to this finitely additive plus μ of at least one set infinite implies $\mu(\text{empty set})$ is equal to 0.
