Lecture – 16 A
Measurable Functions on Measure Spaces

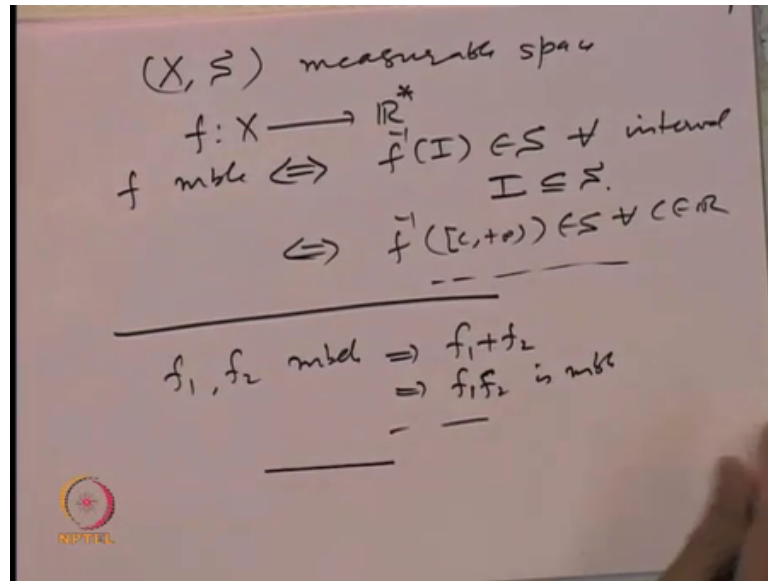

Welcome to lecture number 16 on measure and integration. If you recall in the previous lecture, we had started looking at the notion of measurable functions on measure spaces. We will continue that study of a measurable functions and their properties and then will specialize measurable functions on measure spaces. And then we will look at the space of measurable functions on when x is real line and the sigma algebras are other Borel sigma algebra or Lebesgue sigma algebra and if there is a time will start looking at the integration of non negative simple measurable functions.

(Refer Slide Time: 01:00)

So, let us recall what we had been doing we had been looking at properties of measurable functions; so, that is what will be continue doing. Then we look at measurable functions on measure spaces; look at Borel and Lebesgue measurable functions and then look at integral of non negative simple measurable functions. So, let us just recall what we had done regarding measurable functions.

(Refer Slide Time: 01:25)

We had said that if (X, \mathcal{S}) is a measurable space and f is a function from X to \mathbb{R}^* ; then saying that f is measurable; f measurable it is same as saying the inverse image of every interval; I belongs to \mathcal{S} for every interval, I contained in \mathbb{R}^* . And there were equivalent ways of defining measurability; in terms of special intervals like this is same as if and only if $f^{-1}([c, +\infty)) \in \mathcal{S}$ for every $c \in \mathbb{R}$ and so on.

So, and then we looked at what is called the algebra of measurable functions; we proved that if f_1 and f_2 are measurable; then f_1, f_2 measurable implies $f_1 + f_2$ is measurable implies; $f_1 f_2$ is measurable and so, on. So, today we look at the properties of sequences of measurable functions.

(Refer Slide Time: 02:43)

Properties of measurable functions

Let $f_n : X \rightarrow \mathbb{R}$, $n \geq 1$ be measurable functions. Then

$$(\bigvee_{n=1}^{\infty} f_n)(x) := \max\{f_n(x), n \geq 1\}$$

and

$$(\bigwedge_{n=1}^{\infty} f_n)(x) := \min\{f_n(x), n \geq 1\}$$

are measurable functions.

 NPTEL

So, we want to prove the following namely; look at a sequence f_n of measurable functions; then look at the function what is called the maximum of f_n 's. So, this is a function denoted by $\bigvee_{n=1}^{\infty} f_n$ of x is defined the maximum of f_n of x ; n bigger than or equal to 1. So, this is called the maximum of the sequence f_n and similarly we have the notion of minimum of f_n 's; which is denoted by $\bigwedge_{n=1}^{\infty} f_n$ of x equal to minimum.

So, this is this is extra; so, that is a definition. So, claim is that if f_n is a sequence of measurable functions; then the maximum and the minimum are also measurable functions. So, let us prove this.

(Refer Slide Time: 03:40)

f_n measurable $\forall n \geq 1$.

$$\left(\bigvee_{n=1}^{\infty} f_n\right)(x) := \max\{f_n(x) \mid n \geq 1\}$$

To show $\left(\bigvee_{n=1}^{\infty} f_n\right)$ is measurable.

$$\left(\bigvee_{n=1}^{\infty} f_n\right)^{-1}([c, +\infty)) = \{x \in X \mid \left(\bigvee_{n=1}^{\infty} f_n\right)(x) \geq c\}$$

$$\left(\bigvee_{n=1}^{\infty} f_n\right)^{-1}((-\infty, c]) = \{x \in X \mid \left(\bigvee_{n=1}^{\infty} f_n\right)(x) \leq c\}$$

$$\stackrel{\subseteq S}{=} \bigcap_{n=1}^{\infty} \underbrace{\{x \in X \mid f_n(x) \leq c\}}_{\subseteq S}$$

So, f_n is defined on X to \mathbb{R} and f_n is measurable for every n bigger than or equal to 1. And we define the maximum n equal to 1 to infinity of f_n ; of x to be equal to maximum of $f_n(x)$; n bigger than or equal to 1. So, this is a definition of this maximum and we want to prove to show that this function $\bigvee_{n=1}^{\infty} f_n$; this is measurable. So to prove that we can use any one of those conditions which we had defined earlier for measurability. So, let us look at maximum n equal to 1 to infinity; f_n of inverse of the interval.

Let us look at say C to infinity. So, that means, what? That means, this is all x belonging to X ; such that n equal to 1 to infinity; f_n of x is bigger than or equal to c . So, to prove this now we have to convert some how this relation into individual f_n 's, because each individual f_n is measurable. So, that seems this saying maximum is bigger than or equal to C ; that means, at least one of them cross is over C .

So, that is one way of doing it, but let us look at the equivalent criteria namely let us look at the sets f_n ; inverse the maximum is less than or equal to C . So, that is equal to minus infinity, so to C let us look at that. So, this is same as x belonging to X ; such that the maximum value $f_n(x)$ is less than C . Now, if maximum of something is less than C ; then each one of them has to be less than C . So, that is the reason instead of using this kind of intervals; it is more convenient for the maximum to use this kind of intervals; because on

this set can be written as intersection n equal 1 to infinity of x belonging to x such that; $f_n(x)$ is less than C . So, this is each may be this may not be exactly true.

So, let us take it this close because maximum less than or equal to C then every one of them will be less than or equal to C that is ok. So, we look at the intervals of the type minus infinity C close and that is intersection of the sets and each one of this sets belong to the sigma algebra S . Because each f_n is given to be measurable; so, it is a intersection of elements in the sigma algebra. So, this set also belongs to the sigma algebra S ; so that means, this proves the fact that the maximum of f_n 's is a measurable functions. A similar proof will work for the minimum.

(Refer Slide Time: 07:27)

The whiteboard shows the following derivation:

$$\begin{aligned}
 & c \in \mathbb{R} \\
 & \left(\bigwedge_{n=1}^{\infty} f_n \right)^{-1}([c, +\infty)) = \left\{ x \in X \mid \min_{n \geq 1} f_n(x) \geq c \right\} \\
 & = \bigcap_{n=1}^{\infty} \left\{ x \in X \mid f_n(x) \geq c \right\} \\
 & = \bigcap_{n=1}^{\infty} f_n^{-1}([c, +\infty)) \\
 & \in \mathcal{M}.
 \end{aligned}$$

So, let us look at the wedge; n equal to 1 to infinity f_n that is defined as the minimum of $f_n(x)$; for n bigger than or equal to 1. So, claim is that this is a measurable function. So, once again for any C belonging to \mathbb{R} ; let us look at the minimum of f_n ; n equal to 1 to infinity, inverse of some type of intervals we want to show it belongs to S .

So, let us try looking at minimum of this is bigger than C , so, let us try this. So, this is all x belonging to X ; such that the minimum of $f_n(x)$; n bigger than or equal to 1 is bigger than or equal to C . So, if the minimum of some certain numbers is bigger than or equal to

(Refer Slide Time: 09:56)

Handwritten mathematical definitions on a whiteboard:

$$\forall x \in X$$
$$\limsup f_n(x) = \inf_m \left\{ \sup \{ f_n(x) \mid n \geq m \} \right\}$$
$$(\liminf f_n)(x) := \sup_{m \geq 1} \left\{ \inf \{ f_n(x) \mid n \geq m \} \right\}$$
$$(\limsup f_n)(x) \geq (\liminf f_n)(x)$$
$$f_n(x) \rightarrow f(x) \quad \text{iff} \quad (\limsup f_n)(x) = f(x) = (\liminf f_n)(x)$$

The whiteboard also features a logo for NPTEL in the bottom left corner.

The sequence f_n of functions each f_n is defined from X to \mathbb{R} . So, to define the notion of limit of the f_n at a point x ; what we do is; for every x belonging to X ; let us look at the maximum or the supremum of $f_n(x)$; for n greater than or equal to some stage m . So, this number; the supremum that depends on m and then we take the infimum over all m 's. So, this is supremum; first take the supremum and then take the infimum.

So, this gives you a function; this is called limit superior of f_n at the point x . So, this is called the limit superior of the sequence of functions $f_n(x)$ at the point x . Similarly limit inferior of $f_n(x)$ is; so limit inferior is defined as you first take the infimums of $f_n(x)$; for n greater than or equal to some stage m . And then look at the supremum for all m bigger than or equal to 1; this is called the limit inferior.

And you must have seen in your elementary analysis classes that limit superior of $f_n(x)$ is always bigger than or equal to limit inferior of $f_n(x)$. So, this inequality always holds and the sequence $f_n(x)$ converges to $f(x)$; if and only if limit superior of $f_n(x)$ is equal to $f(x)$; is equal to limit inferior of $f_n(x)$ of x . So, these are elementary facts from basic analysis about when is the sequence of real numbers convergent.

So, it says that a sequence for any sequence of a real numbers or extended real numbers

you can define the concept of limit superior and also you can define the concept of limit inferior. Limit superior is defined by looking at the supremums of the sequence a_n ; from some stage m onwards and then this supremum depends on m , so look at the infimum of all this supremums. So, that is called the limit superior. And similarly limit inferior is defined as first taking the infimums of the sequence $f_n(x)$ from some stage m onwards, and then looking at the supremums of these numbers which depend on m .

And one proves that the limit superior of a sequence is always bigger than or equal to limit inferior and the sequence is convergent if and only if the limit superior is equal to limit inferior. So, in case you have not come across this concepts; I strongly suggest that you pick up a book on elementary analysis and revise a concepts of limit superior and a limit inferior. So, we are going to use that fact now here to prove that f is measurable. So, what is f ? f of x is nothing but limit superior and limit inferior.

So, only thing to show is that the limit superior and limit inferior are both measurable functions.

(Refer Slide Time: 13:54)

$$(\text{Lim sup } f_n)(x) = \inf_{n \geq 1} \left\{ \sup_{n \geq m} (f_n(x)) \right\}$$

Lim sup f_n is measurable
 Lim inf f_n is measurable

$$f_n \rightarrow f = \begin{cases} \text{Lim sup } f_n \\ \text{Lim inf } f_n \end{cases}$$

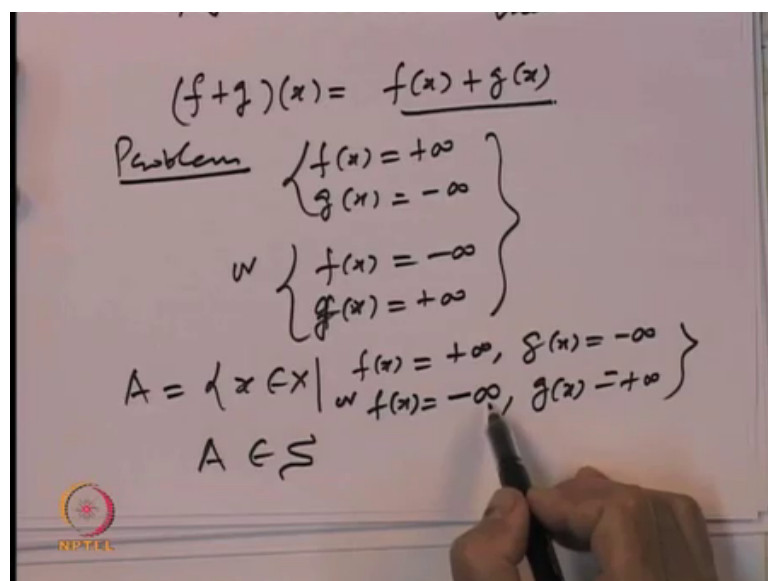

But limit superior of f_n is nothing, but first taking the supremums of $f_n(x)$; from n bigger than equal to m and then taking infimums m bigger than equal to 1. And just now I have

shown that if f_n is a sequence of functions, then the supremums; the maximums are also measurable functions. So, this is a measurable function; infimums of measurable functions that is a measurable function.

So, this implies that limit superior f_n is measurable and similarly limit inferior; f_n is measurable. And saying that f_n converges to f is same as saying; this f is equal to limit superior f_n or also equal to limit inferior of f_n 's. So, that proves the fact that f_n converges to f for every point x ; implies and f_n 's measurable implies f is a measurable function. So, limits of measurable functions are also measurable functions.

So, this proves a theorem that the class of all measurable functions is nice; it is closed under taking point wise limits. Now, let us observe that most of these properties hold for extended real valued functions also when properly defined.

(Refer Slide Time: 15:40)

So, because only thing to observe is the following that if f and g are extended real valued function. And you want to define f plus g ; a care has to be taken because if you will like to define it as f of x plus g of x , but the problem comes if f of x is equal to plus infinity and g of x is equal to minus infinity.

Then what will be this number? That is not defined or f of x is equal to minus infinity and g of x is equal to plus infinity; even then the problem comes this number is not defined. So, what one does is to meaning say suitably defined means look at all the points call this that as a ; where all x belonging to x where either of these things happen, where f x equal to plus infinity; g x is equal to minus infinity or f x equal to minus infinity and g x equal to plus infinity.

Now, one observes that this set A is in the sigma algebra; because f x is equal to plus infinity belongs to sigma algebra intersection of that belongs to sigma algebra. So, all these sets; all this set A is in the sigma algebra. So, A is the set on which the problem can come.

(Refer Slide Time: 17:19)

Handwritten mathematical definition on a whiteboard:

$$(f+g)(x) = \begin{cases} f(x)+g(x) & \text{if } x \notin A \\ \alpha & \text{if } x \in A \end{cases}$$

Ex $f+g$ is σ -measurable.

So, what one does is; one defines f plus g of x to be equal to f x plus g x ; if x does not belong to A and if x belong to A ; you can define it any number α if x belongs to A . So, with this definition it is easy to observe. So, let me leave it as exercise for you to show; that if I define it this way with α any value on the set A ; then f plus g is σ measurable. So, that is what I mean by saying that the above results; most of this properties hold for extended real valued functions also; when this functions are appropriately defined.

So, we will not go much into detail of this; one can easily verify these things.

(Refer Slide Time: 18:14)

Properties of measurable functions

Let $f, g : X \rightarrow \mathbb{R}^*$ be \mathcal{S} -measurable functions. Then

$\{x \in X \mid f(x) > g(x)\}$,
 $\{x \in X \mid f(x) < g(x)\}$,
 $\{x \in X \mid f(x) = g(x)\}$,
 $\{x \in X \mid f(x) \geq g(x)\}$,
 $\{x \in X \mid f(x) \leq g(x)\}$

are all in \mathcal{S} .

 NPTEL

©2006 K. Sreenivas, IIT Bombay. p. 501

So let us look at f and g to be another property of measurable functions as following; let us look at two functions f and g which are measurable; then the following holds; then look at the sets x belonging to X ; say that where $f(x)$ is bigger than $g(x)$ or the set x belonging to X ; where $f(x)$ is strictly less than $g(x)$ or x belonging to X ; where $f(x)$ is equal to $g(x)$ and similarly, where $f(x)$ is bigger than or equal to or $f(x)$ is less than or equal to. So, all these type of sets are claim is; are in the sigma algebra \mathcal{S} . So, let us look at proof of one of them and others will follow similarly.

(Refer Slide Time: 19:03)

The whiteboard contains the following handwritten text:

Pr. Show
 $f, g: X \rightarrow \mathbb{R}, \text{ measurable}$
 $\{x \in X \mid f(x) < g(x)\} \in \Sigma ?$
 $\forall x \in X, \exists \text{ rational } r \text{ such that } f(x) < r < g(x)$
 $\{x \in X \mid f(x) < g(x)\} = \bigcup_{r \in \mathbb{Q}} \{x \in X \mid f(x) < r < g(x)\}$
 $= \bigcup_{r \in \mathbb{Q}} \left(\{x \in X \mid f(x) < r\} \cap \{x \in X \mid r < g(x)\} \right)$

At the bottom left of the whiteboard, there is a small circular logo with the text "NPTEL" below it.

So, f and g are functions X to \mathbb{R} star measurable; let us look at the set x belonging to X ; such that f of x is strictly less than g of x . And so, our aim is to show that this belongs to the sigma algebra Σ and since we are given f and g are both measurable; we are given the property that $f(x) \leq r$ for some real number r belongs to the sigma algebra. And similarly $g(x) \leq r$ for a real number r belongs to the sigma algebra.

So, objective is to try to interpret the set in terms of union intersections of something of sets of the type, where $f(x)$ is less than something and $g(x)$ is less than something. So, for that; we observe that for any x ; if $f(x) < g(x)$, then there must be a rational number in between them. So, for every x belonging to X ; there exist a rational r such that $f(x) < r < g(x)$.

So, here we are using the fact that rationals are dense on the real line. So, with this property, you can write x belonging to X say that $f(x)$ is less than $g(x)$. So, this implies that x belonging to X such that for some rational; $f(x)$ is less than or is less than $g(x)$; for some. And conversely; if for some r this is true then; obviously, $f(x) < r < g(x)$. So, claim is this is equal to union over r belonging to rational numbers.

So, this is the only crucial point in this that the set $f(x) < g(x)$ can be written as a

union over all rationals; such that $f(x)$ is strictly less than r ; strictly less than $g(x)$. And now observe this set is an intersection; so, I can write it as r belonging to \mathbb{Q} ; this set is where $f(x)$ is less than r and $g(x)$ is bigger than r . So, it is x belonging to X such that $f(x)$ less than r intersection; with the set x belonging to X ; such that $g(x)$ is bigger than r .

(Refer Slide Time: 22:01)

$$\begin{aligned} & \{x \in X \mid f(x) < g(x)\} \\ &= \bigcup_{r \in \mathbb{Q}} \left(\underbrace{f^{-1}(-\infty, r)}_{\in \mathcal{S}} \cap \underbrace{g^{-1}(r, +\infty)}_{\in \mathcal{S}} \right) \\ &\in \mathcal{S} \\ \Rightarrow & \{x \in X \mid f(x) < g(x)\}^c \\ &= \{x \in X \mid f(x) \geq g(x)\} \end{aligned}$$

So, what we have done? We have interpreted the set x belonging to X such that $f(x)$ less than $g(x)$ as; so, let us just look at the set again. So, this is union over r belonging to \mathbb{Q} ; what is this set? This is f inverse of $f(x)$ less than r ; that is less than r means it is minus infinity to r . And the second set is nothing but g inverse of $g(x)$ bigger than r , so it is r plus infinity.

So, the set $f(x)$ less than $g(x)$ is written as union over rationals intersections of these two sets. Now f and g being measurable; this set belongs to the sigma algebra; g being measurable, this set belongs to the sigma algebra it is intersection. So, the whole set belongs to the sigma algebra intersection belongs to the sigma algebra and rationals are countable. So, this is a countable union of elements in the sigma algebra. So, this belongs to the sigma algebra; so, what we have shown is the set x belonging to X . So, here $f(x)$ strictly less than $g(x)$; belongs to the sigma algebra \mathcal{S} . So, that proves the first property of the theorem; now if you take just the complement of this set. So, also implies that x belonging to X ; such that $f(x)$ less than $g(x)$ the complement of this set what will be that.

So, that is all x belonging to X such that $f(x)$ is bigger than or equal to $g(x)$. So, that set also belongs to the sigma algebra and similarly the argument; similarly you said that $f(x)$ less than $g(x)$ belongs to it.

(Refer Slide Time: 24:08)

$$\begin{aligned}
 &= \{x \in X \mid f(x) = g(x)\} \\
 &\{x \in X \mid f(x) > g(x)\} \\
 &= \bigcup_{r \in \mathbb{Q}} \left(f^{-1}(r, +\infty) \cap g^{-1}(-\infty, r) \right) \\
 &\in \mathcal{S} \\
 &\{x \in X \mid f(x) \leq g(x)\} \in \mathcal{S}
 \end{aligned}$$

So, let us write x belonging to X ; such that $f(x)$ is strictly bigger than $g(x)$ is also in the sigma algebra. Because by similar arguments, I can write this as the union over all rationals of f inverse of; so $f(x)$ bigger than; so that will be r plus infinity in intersection with g inverse of minus infinity to r ; so, by similar argument, where we had $f(x)$ less than again we can infer $f(x)$ is bigger than $g(x)$. So, there must be a rational in between. So, that must be true and that will imply that this belongs to the sigma algebra. So, saying that $f(x)$ bigger than $g(x)$ belong to the sigma algebra is ok and if you take the complement of this that is nothing, but x belonging to x such that $f(x)$ less than or equal to $g(x)$; so, that also belongs to the sigma algebra because this is the complement of the set in the sigma algebra.

So, measurable sets have nice properties; namely if f and g are measurable; then operations involving measurable sets, measurable functions give you again sets in the sigma algebra. So, these are nice properties and will see a use of these properties soon. So, with this we complete the study of measurable functions on measurable spaces.
