Lecture – 17 A
Integral of Nonnegative Simple Measurable Functions

Welcome to lecture 17 on measure and integration. Today, we will start the topic of integration. First I will explain the building blocks for the integration and how the process will be done.

(Refer Slide Time: 00:31)

So the topic for today's discussion is integral of nonnegative simple measurable functions. See the basic idea is we want to define the notion of integral for a function f defined on a set x taking values in \mathbb{R}^* . So, now, for a function f it is we can represent a function f as the positive part minus the negative part.

(Refer Slide Time: 00:58)

$$f = f^+ - f^-$$
$$\int f = \int f^+ - \int f^-$$
$$f: X \longrightarrow \mathbb{R}^*$$
$$f = \chi_A, \quad A \subseteq X$$
$$\chi_A: X \longrightarrow \mathbb{R}^*$$
$$\chi_A(x) = \begin{cases} 0 & \text{if } x \notin A \\ 1 & \text{if } x \in A \end{cases}$$

NPTTEL

The advantage of doing this is that f plus and f minus both are nonnegative functions and so, it is a and integration being a linear process. So, integral of f is going to be equal to integral of f plus minus integral f minus. So, it is enough to define the notion of integral for nonnegative functions. And for nonnegative functions f on x to are star we recall that we can take it as we look at functions, which are first of all very simple functions for example, let us look at a function f which is a indicator function of a set x . Now of a set a contained in x this is a function which takes only 2 values.

So, indicator function of a is a function on x taking values in \mathbb{R}^* . So, χ_a of a at 0 of at a point x is equal to 0 if x does not belong to a and is 1 if x belongs to a . So, you can one can think of this function taking only 2 values right. Now the value where it is 0 the integral. So, we want to define the notion of integral.

(Refer Slide Time: 02:25)

And this is going to be with respect to a measure μ on X . So, μ a measure on subsets of X . So, we are going to write it as $\int_A 1 d\mu$. So, what it should be on a the value is one. So, we like to put it as one times μ of A , in some sense μ of A is this size of a set and one is the height. So, this is in in a sense the area of the we know the graph of the function. So, let us look at functions which are going to be linear combinations of indicator functions. So, we start looking at the integral of nonnegative simple measurable functions. So, let us recall.

(Refer Slide Time: 03:26)

The slide is titled "Integration" in yellow text on a dark blue background. It contains two bullet points in green text. The first bullet point states: "Unless stated otherwise, we shall now onwards work on a fixed σ -finite complete measure space (X, \mathcal{S}, μ) ." The second bullet point states: "Let \mathbb{L}_0^+ be the class of all nonnegative simple \mathcal{S} -measurable functions on X , i.e., $s : X \rightarrow [0, \infty]$ given by" followed by the formula
$$s(x) = \sum_{i=1}^n a_i \chi_{A_i}(x), \quad x \in X,$$
 where χ_{A_i} is the indicator function. In the bottom left corner, there is a circular logo with the text "NPTEL" below it. In the bottom right corner, there is a small copyright notice: "©2006 K. Ravi, PTI/University of..."

So, will fix our notation that from now onwards we are going to work on a measure space (X, \mathcal{S}, μ) where X is a set \mathcal{S} is a sigma algebra of subsets of X and μ is a measure on defined on \mathcal{S} and this is a complete measure space; that means, that all sets A such that $\mu(A) = 0$ implies A and all its subsets are inside \mathcal{S} .

So, let us denote by \mathbb{L}_0^+ to be the class of all nonnegative simple measurable functions on X . So, now, let us recall what was a nonnegative simple measurable function s , it is a function defined on X taking nonnegative values and it has a representation $s(x) = \sum_{i=1}^n a_i \chi_{A_i}(x)$ where a_i are extended real numbers and the sets A_i are in the sigma algebra \mathcal{S} . So, they are in the sigma algebra \mathcal{S} .

(Refer Slide Time: 04:40)

Integration on \mathbb{L}_0^+

a_1, a_2, \dots, a_n are nonnegative extended real numbers; $A_i \in \mathcal{S}$ for every i ;

$A_i \cap A_j = \emptyset$ for $i \neq j$; and $\bigcup_{i=1}^n A_i = X$.

■ Define for $s \in \mathbb{L}_0^+$, the **integral** of s with respect to μ , by

$$\int s(x) d\mu(x) := \sum_{i=1}^n a_i \mu(A_i).$$

 ©2010 K. Flannery, PT Director - p.4/10

And they are pairwise disjoint; that means, A_i intersection is empty for i not equal to j and the union of these sets is equal to X . So, this is going to be the class of nonnegative simple measurable functions. For such class of functions in this class we are going to define the notion of integral.

So, for a function s in this class if its representation is S given before.

(Refer Slide Time: 05:16)

Integration

- Unless stated otherwise, we shall now onwards work on a fixed σ -finite complete measure space (X, \mathcal{S}, μ) .
- Let \mathbb{L}_0^+ be the class of all nonnegative simple \mathcal{S} -measurable functions on X , i.e., $s : X \rightarrow [0, \infty]$ given by

$$s(x) = \sum_{i=1}^n a_i \chi_{A_i}(x), \quad x \in X,$$

where n is some positive integer;

©2016 K. P. Srinivas, IIT Bombay - p. 5/16

(Refer Slide Time: 05:25)

Integration on \mathbb{L}_0^+

a_1, a_2, \dots, a_n are nonnegative extended real numbers; $A_i \in \mathcal{S}$ for every i ;

$$A_i \cap A_j = \emptyset \text{ for } i \neq j; \text{ and } \bigcup_{i=1}^n A_i = X.$$

- Define for $s \in \mathbb{L}_0^+$, the **integral** of s with respect to μ , by

$$\int s(x) d\mu(x) := \sum_{i=1}^n a_i \mu(A_i).$$

©2016 K. P. Srinivas, IIT Bombay - p. 6/16

So, if $s(x) = \sum_{i=1}^n a_i \chi_{A_i}(x)$, then its integral is defined as $\int s d\mu$. So, integral is noted by $\int s(x) d\mu(x) = \sum_{i=1}^n a_i \mu(A_i)$ that is the value of the function on the set A_i times the measure of the set A_i . So, integral of s with respect to μ as written here is defined as $\sum_{i=1}^n a_i \mu(A_i)$, a_i is the value taken on the set A_i . So, a_i times the size of the set A_i . So, $\mu(A_i)$ sometimes we do not indicate the variable x , we just write as $\int s d\mu$ to be the integral of the

simple function s nonnegative simple measurable function s with respect to μ and let us note here that our representation the integral is with respect to a representation of the function.

(Refer Slide Time: 06:28).

Properties of integral

- The integral $\int s(x)d\mu(x)$ is also denoted by $\int s d\mu$.
- $\int s d\mu$ is well-defined.
- For $s, s_1, s_2 \in \mathbb{L}_0^+$ and $\alpha \in \mathbb{R}$ with $\alpha \geq 0$, the following hold:

$$0 \leq \int s d\mu \leq +\infty.$$

NPTEL © 2019 K. Ramesh, IIT Bombay p. 5/10

So, first of all we would like to show that integral $s d\mu$ is well defined.

(Refer Slide Time: 06:36)

$\int \chi_A d\mu = \mu(A)$ μ a measure on subsets $\neq X$

let $s \in \mathbb{L}_0^+$

$$s = \sum_{i=1}^{\infty} a_i \chi_{A_i} = \sum_{j=1}^{\infty} b_j \chi_{B_j}$$

where $A_i \in \mathcal{S}, B_j \in \mathcal{S}$
 $\bigcup_{i=1}^{\infty} A_i = X, \bigcup_{j=1}^{\infty} B_j = X$
 $A_i \cap A_j = \emptyset, B_i \cap B_j = \emptyset$

NPTEL

So, let us prove that the integral is well defined. So, let us take a function s belonging to L^1 plus 0 . So, it is a nonnegative simple measurable function. So, let us say s is written as $\sum_{i=1}^n a_i \chi_{A_i}$ where the sets A_i belong to the sigma algebra S , B_j belong to the sigma algebra s . And union of A_i is equal to X and union of B_j is also equal to X and these sets are disjoint. So, $A_i \cap A_j = \emptyset$ and $B_i \cap B_j = \emptyset$ for $i \neq j$. So, let us say the set s as got 2 representations possible. So, what we want to show. So, we want to show that the integral of s .

(Refer Slide Time: 07:49)

The image shows a whiteboard with handwritten mathematical derivations. At the top, a question is posed: $\sum_{i=1}^n a_i \mu(A_i) = \sum_{j=1}^m b_j \mu(B_j) ?$. Below this, the first derivation shows: $\sum_{i=1}^n a_i \mu(A_i) = \sum_{i=1}^n a_i \mu(\bigcup_{j=1}^m (A_i \cap B_j))$. This is then simplified to: $= \sum_{i=1}^n a_i \left[\sum_{j=1}^m \mu(A_i \cap B_j) \right]$. A second derivation, labeled "Similarly", shows: $\sum_{j=1}^m b_j \mu(B_j) = \sum_{j=1}^m b_j \left[\sum_{i=1}^n \mu(A_i \cap B_j) \right]$. A small logo for NPTEL is visible in the bottom left corner of the whiteboard image.

So, integral $s d\mu$ is well defined and; that means, what. So, mathematically; that means, we have to show that $\sum_{i=1}^n a_i \mu(A_i) = \sum_{j=1}^m b_j \mu(B_j)$. So, this is what we have to show. So, let us start. So, $\sum_{i=1}^n a_i \mu(A_i)$ I can write it as $\sum_{i=1}^n a_i \mu(\bigcup_{j=1}^m (A_i \cap B_j))$ and then μ of this A_i can be written as union of $A_i \cap B_j$ for $j=1$ to m because union of B_j is equal to X . So, $A_i \cap X = A_i$ and that is same as this now this is a B_j are disjoint. So, these sets are $A_i \cap B_j$ for i fixed are disjoint.

So, by using finite additivity property of the measure we have this is equal to $\sum_{i=1}^n a_i \sum_{j=1}^m \mu(A_i \cap B_j)$ and this is nothing, but $\sum_{j=1}^m b_j \sum_{i=1}^n \mu(A_i \cap B_j)$. And

similarly we can write the other side that is $\sum_{j=1}^m \mu(B_j)$ to be equal to $\sum_{j=1}^m \sum_{i=1}^n \mu(A_i \cap B_j)$. So, the left hand side here is written as this sum the right hand side is written as this sum. Now we want to show that these 2 sums are equal now let us observe that given that the function s has got 2 representations this equal to this. So, how is this function calculated at a point x , if x belongs to A_i the value is a_i and on the other hand it may belong to some B_j the value will be b_j . So, that in in. So, that forces one to say that if x belongs to $A_i \cap B_j$ then a_i must be equal to b_j . So, this is the crucial thing to note here that if s a simple nonnegative simple measurable function is given 2 representations one is $\sum a_i \chi_{A_i}$ and $\sum b_j \chi_{B_j}$. Then for x belonging to $A_i \cap B_j$ the value of s of x on one hand it is a_i other hand it is b_j . So, a_i must be equal to b_j . So, this is the crucial thing to note. So, let us make this observation and write it out. So, note that.

(Refer Slide Time: 11:13)

Note that if $x \in A_i \cap B_j$
 then $s(x) = a_i = b_j$
 if $x \notin A_i \cap B_j$, $s(x) = 0$
 \Rightarrow from (1) and (2)
 $\sum_{i=1}^n a_i \mu(A_i) = \sum_{j=1}^m b_j \mu(B_j)$
 i.e. $\int s d\mu =$ well defined

So, note that if x belongs to $A_i \cap B_j$. If x belongs to $A_i \cap B_j$, then s of x is equal to a_i it is also equal to b_j . So, a_i is equal to b_j and if x does not belong to $A_i \cap B_j$, then s of x is equal to 0. So; that means, in this summation in the summation whenever x belongs to $A_i \cap B_j$ this a_i is going to be equal to b_j otherwise in the sum the term does not matter. So, that proves the fact that. So, that will imply from this 2 equations from equation one and equation 2. So, this implies from

equation 1 and 2 that $\sum_{i=1}^n A_i \mu(A_i) = \sum_{j=1}^m B_j \mu(B_j)$.

So, that is $\int s d\mu$ can be defined as either of these sums. So, it is equal to either this or this is well defined. So, the integral of a nonnegative simple measurable function. So, we can choose any representation of we can choose any representation of the nonnegative simple function and define its integral in terms of that. Next let us look at properties of this integral. So, we are going to look at functions s_1, s_2 which are nonnegative simple measurable functions. α will be a real number $\alpha \geq 0$ then we are going to look at what happens to various properties of.

So, first observation is that $\int s d\mu$ is a nonnegative number. It could be equal to plus infinity. So, $\int s d\mu$ is an extended nonnegative real number. That is obvious because what is $\int s d\mu$ is summation of $A_i \mu(A_i)$ all the terms are nonnegative. So, this is a nonnegative number. So, this is an obvious property the second property.

(Refer Slide Time: 13:52)

Properties of integral

- $\alpha s \in \mathbb{L}_0^+$ and $\int (\alpha s) d\mu = \alpha \int s d\mu.$
- $s_1 + s_2 \in \mathbb{L}_0^+$ and $\int (s_1 + s_2) d\mu = \int s_1 d\mu + \int s_2 d\mu.$
- For $E \in \mathcal{S}$ we have $s\chi_E \in \mathbb{L}_0^+$, and $E \longmapsto \nu(E) := \int s\chi_E d\mu$

is a measure on \mathcal{S} .

NPTEL

©2014 K. Prasad, IIT Bombay. 13:52

We want to check that for a nonnegative simple function s αs belongs to L_0^+ and the integral of $\alpha s d\mu$ is same as α times the integral of $s d\mu$. So, let us

check that.

(Refer Slide Time: 14:08)

$$s = \sum_{i=1}^n a_i \chi_{A_i}, \quad \bigcup_i A_i = X$$

$$\alpha \in \mathbb{R}^+, \quad \alpha \geq 0,$$

$$\alpha s = \sum_{i=1}^n (\alpha a_i) \chi_{A_i}, \quad \bigcup_i A_i = X$$

$$\int \alpha s \, d\mu = \sum_{i=1}^n (\alpha a_i) \mu(A_i)$$

$$= \alpha \left(\sum_{i=1}^n a_i \mu(A_i) \right)$$

$$= \alpha \int s \, d\mu$$

So, s belongs to L^0 plus 0 is a nonnegative simple measurable function. So, let us write let us write s is equal to $\sum_{i=1}^n a_i \chi_{A_i}$, indicator function of A_i where $\bigcup_i A_i = X$. So, whenever it is a partition we will write as this square bracket union over i equal to X . And α is a nonnegative α belonging to \mathbb{R}^+ bigger than or equal to 0, then αs of s . So, has the representation it is $\sum_{i=1}^n (\alpha a_i) \chi_{A_i}$ and A_i are still a partition of X , but; that means, if this is the representation.

So, $\int \alpha s \, d\mu$ integral of αs with respect to μ is going to be equal to by our definition, $\sum_{i=1}^n \alpha a_i \mu(A_i)$ and this is a finite sum nonnegative everything. So, α comes out α times the summation of $\sum_{i=1}^n a_i \mu(A_i)$ and that is nothing, but α times integral of $s \, d\mu$. So, that proves the property that the integral of nonnegative simple functions is if you multiply it by a constant α then the α comes out. So, $\int \alpha s \, d\mu$ is equal to $\alpha \int s \, d\mu$. Next we want to show that it is a linear operation. So, we want to check that if s_1 and s_2 belong to L^0 plus then $s_1 + s_2$ belong to L^0 plus that we have actually we have already checked, but will check it again today also and the integral of $s_1 + s_2 \, d\mu$ is integral of s_1 plus integral of s_2 . So, for such things we have.

(Refer Slide Time: 16:24)

$$\begin{aligned} \text{Let } s_1 &= \sum_{i=1}^n a_i \chi_{A_i}, \quad \sqcup A_i = X \\ s_2 &= \sum_{j=1}^m b_j \chi_{B_j}, \quad \sqcup B_j = X \\ s_1 &= \sum_{i=1}^n \sum_{j=1}^m a_i \chi_{A_i \cap B_j} \\ s_2 &= \sum_{i=1}^n \sum_{j=1}^m b_j \chi_{A_i \cap B_j} \\ s_1 + s_2 &= \sum_{i=1}^n \sum_{j=1}^m (a_i + b_j) \chi_{A_i \cap B_j} \end{aligned}$$

$\left. \begin{array}{l} \sum_{i=1}^n \sum_{j=1}^m \chi_{A_i \cap B_j} \\ \sum_{i=1}^n \sum_{j=1}^m \chi_{A_i \cap B_j} \end{array} \right\} \sqcup_{i,j} (A_i \cap B_j) = X$

So, let us take a function s_1, s_2 belonging to L^+ . So, nonnegative simple measurable function. So, let us write let s_1 be equal to $\sum_{i=1}^n a_i \chi_{A_i}$ where A_i is form a partition of X and later write s_2 a $\sum_{j=1}^m b_j \chi_{B_j}$ where B_j is a partition of X . So, if you recall we had said that we can bring the both s_1 and s_2 a common partition and what is that common partition $A_i \cap B_j$.

So, what we are saying is you can write s_1 as $\sum_{i=1}^n \sum_{j=1}^m a_i \chi_{A_i \cap B_j}$ and also similarly s_2 can be written as $\sum_{i=1}^n \sum_{j=1}^m b_j \chi_{A_i \cap B_j}$. Now here note that $\sum_{i=1}^n \sum_{j=1}^m \chi_{A_i \cap B_j}$ is a partition of the whole space that is equal to X . So, this is the point to be sort of noted that whenever you are given 2 functions s_1 and s_2 with 2 representations, which involves some partitions A_i and partition B_j then we can bring them to a common partition namely $A_i \cap B_j$ and now we can define what is $s_1 + s_2$. So, $s_1 + s_2$ is going to be equal to $\sum_{i=1}^n \sum_{j=1}^m (a_i + b_j) \chi_{A_i \cap B_j}$. That is clear because on $A_i \cap B_j$ s_1 is a_i and on $A_i \cap B_j$ s_2 is b_j . So, $s_1 + s_2$ will be equal to $a_i + b_j$ on $A_i \cap B_j$. So, once we have got on a representation of $s_1 + s_2$. We can define what is the integral of $s_1 + s_2$.

(Refer Slide Time: 19:09)

$$\begin{aligned}
 &= \sum_{i=1}^n \sum_{j=1}^m a_i \mu(A_i \cap B_j) + \sum_{i=1}^n \sum_{j=1}^m b_j \mu(A_i \cap B_j) \\
 &= \sum_{i=1}^n a_i \sum_{j=1}^m \mu(A_i \cap B_j) + \sum_{j=1}^m b_j \left(\sum_{i=1}^n \mu(A_i \cap B_j) \right) \\
 &= \sum_{i=1}^n a_i \mu(A_i) + \sum_{j=1}^m b_j \mu(B_j) \\
 &= \int A_1 d\mu + \int A_2 d\mu.
 \end{aligned}$$

So, this representation gives us that integral of $s_1 + s_2 d\mu$ is equal to summation over $i=1$ to n summation over $j=1$ to m of $A_i + B_j$ into μ of $A_i \cap B_j$ right. So, because this is a representation. So, $A_i + B_j$ is a value on the set $A_i \cap B_j$. So, the integral is going to be equal to summation over i summation over j of $A_i + B_j$ the value on the set $A_i \cap B_j$. Now the right hand side we can write split. So, that is equal to 2 terms, one is summation over i summation over j of A_i times μ of $A_i \cap B_j$ plus the second term summation $i=1$ to n summation $j=1$ to m of b_j . So, A_i second term is $B_j \mu$ of $A_i \cap B_j$. And now these are all finite sums.

So, we can write the first term as $\sum_{i=1}^n a_i$ take A_i outside and this is summation of μ of $A_i \cap B_j$ because this is summation over i only. So, you can take it out over $j=1$ to m of $A_i \cap B_j$ plus here summation over j and summation over i . So, will write it as summation over j first B_j and inside is summation over i equal to I have interchanged the order of summation there finite terms only finite sums only. So, that is allowed. So, that is one of μ of $A_i \cap B_j$ and now we observed that the first sum by the finite additivity property of the measure is nothing, but μ of A_i and this summation over I this sum is nothing, but μ of B_j because A_i is form a partition of x and here b_j forms.

So, first term is equal to summation i equal to 1 to n A_i mu of A_i plus summation j equal to 1 to m B_j of mu of B_j . And now clearly this is integral of s_1 $d\mu$ plus the second term is integral of s_2 $d\mu$. So, that proves the fact that integration is a linear process namely all integral, if s_1 and s_2 are in L^0 plus then s_1 plus s_2 also is in L^0 plus and the integral of s_1 plus s_2 is equal to integral of s_1 plus integral of s_2 . Next property we want to check is the following that for a set if E is a set in the sigma algebra \mathcal{S} and we multiply s nonnegative simple measurable function by the indicator function of e , then that function also belongs to a L^0 plus that again we had checked earlier when we defined nonnegative simple measurable functions. So, it is integral is defined and we want to check that $\int s \chi_E d\mu$ which is integral of s indicator function of e $d\mu$ is actually a measure on S .

So, this gives a method of generating more measures on the sigma algebra \mathcal{S} . So, let us prove this property. So, let us take a function.

(Refer Slide Time: 23:15)

The image shows a whiteboard with the following handwritten mathematical derivations:

$$s = \sum_{i=1}^n a_i \chi_{A_i}, \quad \bigcup_{i=1}^n A_i = X$$

$$E \in \mathcal{S}$$

$$s \cdot \chi_E = \sum_{i=1}^n a_i \chi_{A_i} \chi_E$$

$$= \sum_{i=1}^n a_i \chi_{A_i \cap E}, \quad \bigcup_{i=1}^n (A_i \cap E) = E$$

$$\int s \chi_E d\mu = \sum_{i=1}^n a_i \mu(A_i \cap E)$$

In the bottom left corner of the whiteboard, there is a logo for NPTEL.

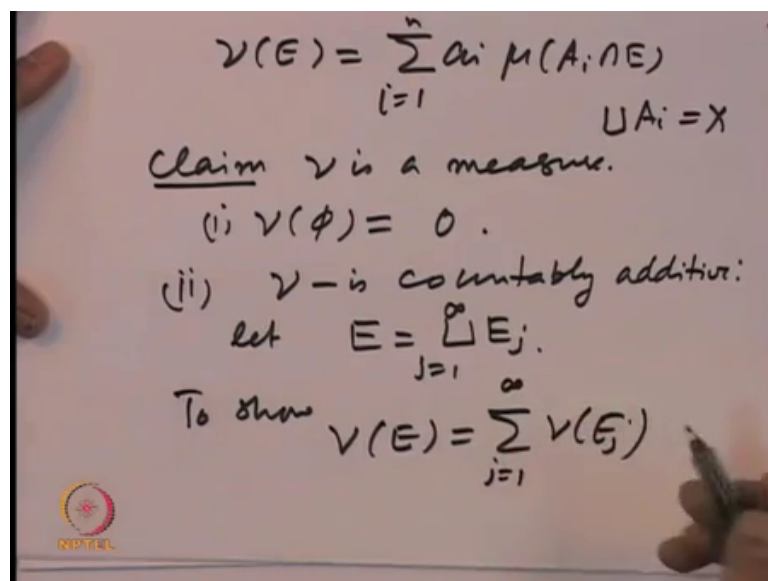

So, let us take a nonnegative simple measurable function L^0 plus s of given by sigma i equal to 1 to n , A_i indicator function of A_i where union of A_i is equal to X . And E is a fixed set in the sigma algebra \mathcal{S} . Then s times the indicator function of e . So, multiply this equation on both sides where indicator function that is i equal to 1 to n A_i χ_{A_i} multiplied by χ of e . And now here is the observation that the product of indicator

function of 2 sets is nothing, but the indicator function of the intersection. So, this can be written as i equal to 1 to n A_i this product indicator function of A_i into indicator function of each can be written as the indicator function of A_i intersection E .

So, that is only observation one has to make and now. So, s times indicator function of E is given by this. So, where union of A_i intersection E what will be that that is the disjoint union giving you the set E . And on E complement this functions is 0. So, if you like you can add one more term here 0 times the indicator function of E complement, but that is not. So, normally whenever the that kind of a set that term will not mention it here. So, a automatically on the complement it is 0 and that gives a partition of the set.

So, this means s of indicator function of E is A_i times indicator function of A_i intersection E where these things form a partition. So, that implies s times the indicator function of E is a nonnegative simple measurable function and what is the integral of that. So, integral of s chi of E $d\mu$ is equal to sigma i equal to 1 to n A_i μ of A_i intersection E . So, that is a integral of this function. So, we want to prove that, if we call this as ν of E , that is a measure. So, let us check that property to check it is a measure what we have to check.

(Refer Slide Time: 25:56)

So, ν of ν of a set E is defined as sigma by our previous calculations A_i times μ of A_i

intersection E , i equal to 1 to n where A_i are partition of X and a_i are in the sigma algebra always. So, claim ν is a measure right. So, what is to we checked ν of empty set equal to E is empty set. So, μ of A_i intersection E that is empty set. So, that is 0. So, it is equal to 0 what is the second property you want to check ν is countably additive. So, for that. So, let us write let E be equal to union of E_j , j equal to 1 to infinity where all the sets are in the sigma algebra. So, you want to show that to show ν of E is equal to $\sum \nu$ of E_j , j equal to 1 to infinity. So, that is what we have to show. So, let us compute both sides and show the required property. So, let us look at ν of E .

(Refer Slide Time: 27:27)

$$\begin{aligned}
 &= \sum_{i=1}^n a_i \mu \left(A_i \cap \left(\bigcup_{j=1}^{\infty} E_j \right) \right) \\
 &= \sum_{i=1}^n a_i \mu \left(\bigcup_{j=1}^{\infty} (A_i \cap E_j) \right) \\
 &= \sum_{i=1}^n a_i \left(\sum_{j=1}^{\infty} \mu(A_i \cap E_j) \right) \\
 &= \sum_{j=1}^{\infty} \left(\sum_{i=1}^n a_i \mu(A_i \cap E_j) \right) \\
 &= \sum_{j=1}^{\infty} \nu(E_j)
 \end{aligned}$$

So, ν of E is equal to $\sum_{i=1}^n a_i \mu$ of A_i intersection E by definition right ν of E is defined as this things in what is E let us put the prop value of e . So, it is i equal to 1 to n $a_i \mu$ of A_i intersection union disjoint union e_j , j equal to 1 to infinity right that is by the definition of by the fact that E is at disjoint union of e_j , but that we can write it as summation i equal to 1 to n $a_i \mu$ of so this is nothing, but. So, we can write it as disjoint union over j 1 to infinity of A_i intersection e_j right by the distributive property of intersection over union. So, this is a countable disjoint union of sets in the sigma algebra. So, by the countable additive property of the measure μ this term is equal to summation i equal to 1 to n a_i summation j equal to 1 to infinity of μ A_i intersection e_j right. And now note that we have got 2 sums here one is summation A_i another is summation j equal to 1 to infinity and all are non negative extended real numbers. So, we

can interchange the order of integration without any problem.

So, we can write this as summation over j first then summation over $i = 1$ to n $\mu(A_i \cap E_j)$. So, we write this as this. So, now, note that this the term summation over $i = 1$ to n $\mu(A_i \cap E_j)$ is nothing, but the μ of E_j . So, by definition this is summation over $j = 1$ to n $\mu(E_j)$. So, this is $\mu(E)$. So, we have shown that $\nu(E)$ is summation $\mu(E_j)$ whenever E is equal to union of disjoint by (Refer Time: 30:00) disjoint sets E_j . So, that proves that ν is a measure. So, we have proved this property also that for a set E in \mathcal{S} the integral $\int \mathbf{1}_E d\nu$ is a nonnegative simple measurable function, and if it is integral is denoted by $\nu(E)$ then $\nu(E)$ is a measure as E varies over measurable sets and this measure has a very nice property. So, this ν measure $\nu(E)$ has a very nice property that $\nu(E) = 0$ whenever $\mu(E) = 0$.

(Refer Slide Time: 30:35)

The slide has a dark blue header with the word "Properties" in yellow. Below the header, the word "Further," is written in yellow. The main content of the slide is the mathematical statement $\nu(E) = 0$ whenever $\mu(E) = 0, E \in \mathcal{S}$, written in yellow. In the bottom left corner, there is a circular logo with a globe and the text "NPTEL" below it. In the bottom right corner, there is a small copyright notice: "©2011 K. Prasad, IIT Bombay. p. 110".

(Refer Slide Time: 30:46)

$$\nu(E) = \sum_{i=1}^n a_i \mu(A_i \cap E)$$

$\cup A_i = X$

$$\text{If } \mu(E) = 0$$
$$\Rightarrow \mu(A_i \cap E) = 0 \quad (\because A_i \cap E \subseteq E)$$
$$\Rightarrow \nu(E) = 0$$
$$\underline{\underline{\mu(E) = 0 \Rightarrow \nu(E) = 0}}$$

So, let us just check that property again check that property then ν of E is defined as summation i equal to 1 to n $A_i \mu$ of A_i intersection, E where union of A is equal to x . So, if μ of E is equal to 0 that will imply that μ of each A_i intersection E is also 0 because A_i intersection E is a subset of E and μ is a measure. So, μ is also monotone right. So, μ being monotone μ of a intersection E is less than or equal to μ of E which is equal to 0 so; that means, this is equal to 0. So, implies ν also. So, each term in the definition of ν of E is zero; that means, ν of E is 0.

So, this ν measure which is defined where integration of nonnegative simple functions has the property that μ of E equal to 0 implies ν of E equal to 0. This say is a very special property. So, it relates 2 measures μ and ν ; that means, it says whenever E is a set of measure 0 for μ it is also a set of measure 0 for ν and later on almost in the end of the course, will characterize such measures whenever 2 measures are related by this there is a theorem which says that ν must be representable as integral with respect to μ .

So, will come to that theorem bit late in our course when we are finish integration and some other more properties of it. So, this ν of E which is written as which is a integral is having a special property and let us also mention that integral of s indicator function of E $d\mu$ is also written as integral E of $s d\mu$. So, this is another way of writing. So, this is called integral of s over E . So, this. So, you say this is integral of s over the set E . So, that

is the notation will follow because outside E s is 0 in this representation.
