Lecture – 18A
Properties of Nonnegative Simple Measurable Functions

Welcome to lecture number 18 on measure and integration. If you recall in the previous lecture we were defined the notion of integral for nonnegative simple measurable functions and we are started looking at the properties of this integral. So, we will continue this study of the properties of the integral for nonnegative simple measurable functions, and then later on we will extend it to this integral to nonnegative measurable functions.

(Refer Slide Time: 00:51)

So, topics for today would be properties of integral for non negative simple measurable functions, continue the study of that and then define integral for non negative simple func measurable functions. If you recall me at the last property that we have proved in the previous lecture was that if s_n is any increasing sequence of nonnegative measurable functions.

(Refer Slide Time: 01:05)

Properties

- If $\{s_n\}_{n \geq 1}$ is any increasing sequence in \mathbb{L}_0^+ such that $\lim_{n \rightarrow \infty} s_n(x) = s(x), x \in X$, then
$$\int s d\mu = \lim_{n \rightarrow \infty} \int s_n d\mu.$$
- $\int s d\mu = \sup \left\{ \int s' d\mu \mid 0 \leq s' \leq s, s' \in \mathbb{L}_0^+ \right\}.$

NPTEL

Such that they converge to a simple nonnegative simple function s of x then integral of s is equal to limit of integral of $s_n d\mu$ so; that means, under increasing limits if the limit is again a nonnegative simple measurable function then you can interchange the order of integration and the notion of limit. So, integral of $s d\mu$ which is s is the limit of a $s_n d\mu$ s_n 's is same as limit of n going to infinity of integral s_n 's $d\mu$. So, integrals of s_n 's converged to integral of s .

Let us observe one more simple property of this integral for any nonnegative simple measurable function s the integral $s d\mu$ can also be represented as the supremum of the integrals of s' $d\mu$ where s' primes are nonnegative simple measurable functions less than x less than s this property is obvious because s' is less than or equal to s . So, the supremum has to be at least integral $s d\mu$, and it cannot be more because s' less than s implies that integral of s' is less than or equal to integral s . So, the supremum they cannot be bigger than or equal to $s d\mu$ also. So, this is obvious property, but we will see later on extension of this property later on.

The next let us observe another important property about the integral of nonnegative simple measurable functions and that is the following.

(Refer Slide Time: 02:54)

Properties

Let $\{s_n\}_{n \geq 1}$ and $\{s'_n\}_{n \geq 1}$ be increasing sequences in \mathbb{L}_0^+ such that

$$\lim_{n \rightarrow \infty} s_n(x) = \lim_{n \rightarrow \infty} s'_n(x).$$

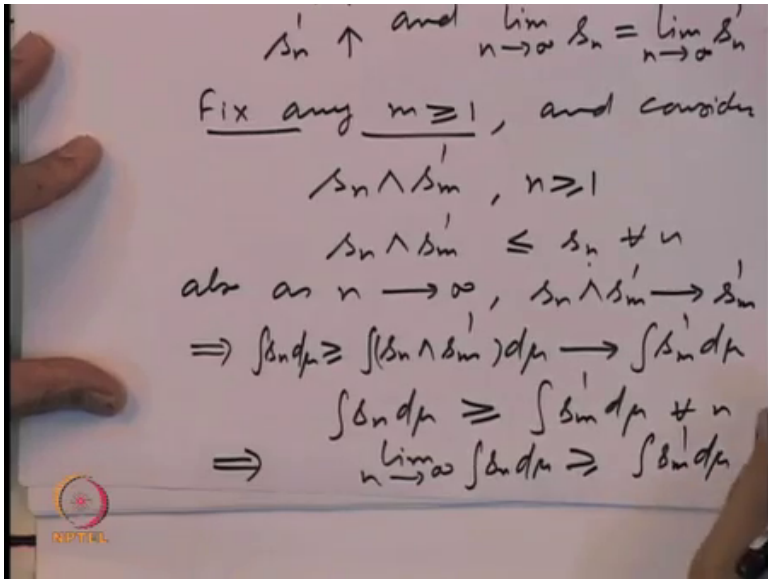

Then

$$\lim_{n \rightarrow \infty} \int s_n d\mu = \lim_{n \rightarrow \infty} \int s'_n d\mu.$$

©2006 P. Ramesh, IIT Bombay - p.413

Suppose s_n and s'_n are 2 increasing sequences of nonnegative simple measurable functions, both converging to the same limit. So, limit of $s_n(x)$ is same as limit of $s'_n(x)$. Then the claim is that the limit of $\int s_n d\mu$ has to be equal to the limit $\int s'_n d\mu$; that means, if two sequences of nonnegative simple measurable functions have the same limit then their integrals also converged to the same values.

(Refer Slide Time: 03:38)

$s'_n \uparrow$ and $\lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} s'_n$

Fix any $m \geq 1$, and consider

$$s_n \wedge s'_m, n \geq 1$$
$$s_n \wedge s'_m \leq s_n + \frac{1}{n}$$

also as $n \rightarrow \infty, s_n \wedge s'_m \rightarrow s'_m$

$$\Rightarrow \int s_n d\mu \geq \int (s_n \wedge s'_m) d\mu \rightarrow \int s'_m d\mu$$
$$\int s_n d\mu \geq \int s'_m d\mu + \frac{1}{n}$$
$$\Rightarrow \lim_{n \rightarrow \infty} \int s_n d\mu \geq \int s'_m d\mu$$

So, let us prove this result from we have got a s_n is a sequence of nonnegative simple measurable functions, s_n 's are increasing and also s'_n is another sequence which is

also increasing, and the limit n going to infinity of s_n is equal to limit n going to infinity of s_n . So, that is given to us.

So, now let us fix any integer a positive integer m bigger than or equal to 1 and consider the sequence s_n minimum s_m . Look at this sequence n bigger than or equal to one. So, look at this functions. So, this is these are the functions which have the property that s_n which s_m is always this is the minimum. So, it is less than or equal to s_n for every n , also as n goes to infinity look at the sequence s_n which s_m . So, the minimum of s_n and s_m as n goes to infinity s_n is going to increase to a limit. So, it will take over s_m at some stage so that means, this is going to converge to s_m . So, this is obvious because s_n and s_m both the sequences are the same limit. So, at some stage s_n will cross over s_m for every m fixed. So, a fixed and integer m .

So, that implies that integral of s_n wedge s_m $d\mu$ will converge to integral of s_m $d\mu$. So, once and this is bigger than or equal to. So, this is less than or equal to integral of s_n $d\mu$ and that is because of this. So, we have got integral s_n $d\mu$ is bigger than or equal to integral s_m $d\mu$ for every m so that means. So, this implies for all n large enough so that implies that limit of n going to infinity of integral s_n $d\mu$ is bigger than or equal to integral s_m $d\mu$. For every m fix and hence because this is true for every m fix; so, this implies that this is true for every m fix.

(Refer Slide Time: 06:35)

$$\Rightarrow \lim_{n \rightarrow \infty} \int s_n d\mu \geq \lim_{m \rightarrow \infty} \int s'_m d\mu$$

Similarly

$$\Rightarrow \lim_{m \rightarrow \infty} \int s'_m d\mu \geq \lim_{n \rightarrow \infty} \int s_n d\mu$$

$$\Rightarrow \lim_{m \rightarrow \infty} \int s'_m d\mu = \lim_{n \rightarrow \infty} \int s_n d\mu \quad \square$$

So, that implies that limit n going to infinity integral s_n $d\mu$ is bigger than or equal to limit m going to infinity of integral s_m $d\mu$. So, we have strong that limit of s_n integral s_n $d\mu$ is bigger than or equal to limit of integral s_m 's, and because now you can interchange that to so that implies similarly limit n going to infinity integral s_n $d\mu$ is bigger than or equal to limit n going to infinity of integral s_n $d\mu$. So, that proves that the two are equal. So, this will prove that limit m going to infinity of integral s_m $d\mu$ is equal to limit n going to infinity of integral s_n $d\mu$. So, that proves the result namely if s_n and s_n dash are to increasing sequences of nonnegative simple functions, having the same limit then their integrals also converged to the same limit this will be used soon.

(Refer Slide Time: 08:05)

Note

- In general \mathbb{L}_0^+ need not be closed under limiting operations.

Consider the Lebesgue measure space $(\mathbb{R}, \mathcal{L}, \lambda)$, and let for every $n \geq 1$,

$$s_n(x) = \sum_{k=1}^n k \chi_{(k-1, k]}(x), \quad x \in \mathbb{R}.$$

NPTEL

© 2011 Rice University. All rights reserved.

Let us look at an observation that in general the class of nonnegative simple measurable functions need not be closed under limiting operations. We showed that some of nonnegative simple measurable functions is a nonnegative simple measurable function, and we also just now observed that if a sequence s_n is increasing to a sequence in L^+ that means, if a sequence of nonnegative simple measurable functions converges to a nonnegative simple measurable function then the integrals converge. In general for decreasing sequences in L^+ for example, this need not hold or for even the limit of nonnegative simple measurable functions may not be a nonnegative simple measurable function. So, to give an example of that let us consider the Lebesgue measurable space

measure space $(X, \mathcal{L}, \lambda)$ where X is the real line, \mathcal{L} is the sigma algebra of Lebesgue measurable sets and λ is the Lebesgue measure.

So, let us define s_n of x for every $n \in \mathbb{N}$ to be equal to the indicator function of $[k-1, k]$ where k goes from 1 to n . So, this is just a text the constant value k on the interval $[k-1, k]$. So, as is quite clear that as n increases this is going to be an increasing sequence that also is clear and the limit as n increases to a function which is equal to k on every interval $[k-1, k]$ so, that the limit function is not going to be a nonnegative simple measurable function of course, it will be a nonnegative measurable function. So, the aim what we are saying is that the class L^+ is not closed under limiting operations. So, that says that we should go over to bigger class of functions namely the class of nonnegative measurable functions and define integral there also.

(Refer Slide Time: 10:31).

Integral of nonnegative measurable functions

- Let \mathbb{L}^+ be the class of all nonnegative functions $f : X \rightarrow \mathbb{R}^+$ which are \mathcal{S} -measurable.

Recall, for $f \in \mathbb{L}^+$, there exists an increasing sequence of functions $\{s_n\}_{n \geq 1}$ in \mathbb{L}_0^+ such that

$$f(x) = \lim_{n \rightarrow \infty} s_n(x) \quad \forall x \in X.$$

NPTEL © 2011

So, let us define for let will denote by L^+ the class of all nonnegative functions $X \rightarrow \mathbb{R}^+$ which are \mathcal{S} measurable keep in mind we have got a fix measures space which is complete that is (X, \mathcal{S}, μ) .

So, look at all non-negative \mathcal{S} measurable functions on the set X and let us denote that that this class of functions by L^+ , and if you recall we had proved a theorem that for a nonnegative measurable function there is a sequence of nonnegative simple measurable functions which is increasing to f . So, for every f belonging to which is a nonnegative

measurable function. So, the function in the class L^+ plus, we know that there exists a sequence s_n of nonnegative simple measurable functions, s_n which increases to f . So, f is a limit of increasing sequence of nonnegative simple measurable functions, and we know we are now just we have defined the concept of integral for nonnegative simple measurable functions s_n . So, it is natural to defined integral of f , to be nothing, but the limit of integrals of s_n 's

(Refer Slide Time: 11:57)

Definition:

- For a function $f \in \mathbb{L}^+$, we define the **integral** of f with respect to μ by

$$\int f(x) d\mu(x) := \lim_{n \rightarrow \infty} \int s_n(x) d\mu(x)$$
 where $\{s_n\}_{n \geq 1}$ is any sequence in \mathbb{L}_0^+ increasing to f .

$$\int f d\mu \text{ is well-defined and } \int f d\mu \geq 0.$$

NPTEL ©John F. Folland, 2011

So, we define. So, for a function f in L^+ plus, we define its integral with respect to μ . So, denoted by $\int f(x) d\mu(x)$ or simply by $\int f d\mu$ to be the limit n going to infinity of $\int s_n(x) d\mu(x)$ where s_n is any sequence in L_0^+ increasing to f and the first obvious claim is that this integral is well defined, it does not depend upon the choice of the sequence s_n that we take which increases to the function f , that is because just now we have proved the result that if there are two different sequences s_n and $s_{n'}$, nonnegative simple measurable both increasing to f then their limits are same.

So, whichever sequence we take s_n which increases to f , its limit is going to be the same extended real number and that extended real number is called the integral of $f d\mu$. So, $\int f d\mu$ is well defined. So, well defined so; that means, whatever sequence s_n increasing to f we choose it does not matter, that limit of that a sequence is same limit of integrals of s_n 's is same. So, that is called integral of $f d\mu$; and because it is limit of integrals of s_n 's which are nonnegative simple measurable function. So, each integral s_n

is a nonnegative simple measurable function. So, as a result the limit also is non-negative. So, integral of a nonnegative measurable function f , by this process is a well-defined number and it is bigger than or equal to 0.

(Refer Slide Time: 13:47)

Properties

- Clearly, $\mathbb{L}_0^+ \subseteq \mathbb{L}^+$ and $\int s d\mu$ for an element $s \in \mathbb{L}_0^+$ is the same as $\int s d\mu$, for s as an element of \mathbb{L}^+ .
- If $f \in \mathbb{L}^+$ and $s \in \mathbb{L}_0^+$ is such that $0 \leq s \leq f$, then $\int s d\mu \leq \int f d\mu$ and

NPTEL logo and footer: ©2011 K. Papp, PT Dunder - p.813

So, now let us look at the properties of this that the class L_0 plus is a subset of L plus. So, that is obvious and we want to claim that integral of $s d\mu$ as an element of s is same as an element of L plus. So, that also is obvious because of the following fact.

(Refer Slide Time: 14:17)

Handwritten notes on a whiteboard:

$$s \in \mathbb{L}_0^+, \int s d\mu$$

$$\mathbb{L}_0^+ \subseteq \mathbb{L}^+, s \in \mathbb{L}^+ =$$

$$s_n = s + s$$

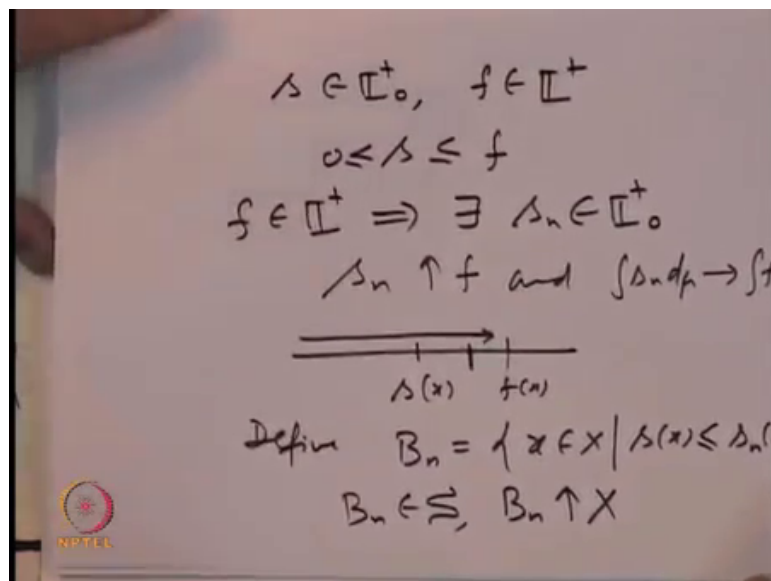

$$\Rightarrow \int s d\mu = \int s d\mu$$

NPTEL logo is visible in the bottom left corner.

So, we have got. So, let us take s belonging to L^+ , and then we have its integral $\int s d\mu$ as a integral of a nonnegative simple function and L^+ we are now treating it as a subset of L^+ . So, when, if you treat s as an element in L^+ , then we can take the constant sequence s_n is equal to s for every s and that will imply that integral of $s d\mu$ as an element in L^+ is same as limit of integral s_n which is same as integral $s d\mu$ as an element in L^+ . So, as if you take a nonnegative simple measurable function and as a element of L^+ , and look at the integrals as a element of L^+ then that integral is same as an element of the non-negative simple measurement; that means, that the new integral that we are defined is in fact, an extension of the notion of integral from non-negative simple measurable functions to nonnegative measurable functions.

Now, next let us look at the property that if f is a function in L^+ then s is a function in L^+ such that $0 \leq s \leq f$, then integral of $s d\mu$ is integral less than or equal to integral $f d\mu$. So, let us prove this property.

(Refer Slide Time: 16:03)

So, we have got s a nonnegative simple measurable function, and f is a nonnegative measurable function and we are given that s is less than or equal to f . Now since f belongs to L^+ implies there is a sequence s_n of nonnegative simple measurable functions such that s_n increases to f right. So, now, let us look at s_n increase to f and the integral of $s_n d\mu$ converges to integral $f d\mu$; now next let us look at. So, consider. So, observe here is s and s of x for any point and here will be some f of x , and s_n is going to

increase to f . So, $s_n(x)$ is going to cross over $s(x)$ for some n . So, let us define B_n to be the set of all those points x belonging to X such that $s(x)$ is less than or equal to $s_n(x)$.

So, observations that this said B_n is in the sigma algebra \mathcal{S} , and because s_n is increasing this sequence B_n of sets is also increasing to the whole space X ; because s_n is converging to $f(x)$. So, B_n is going to increase to \mathcal{S} of X . So, these are obvious properties because if s_n is bigger than or equal to $s(x)$, then s_{n+1} is also bigger than; that means, B_n is inside B_{n+1} and as we have observed that for every x there will be some n such that $s_n(x)$ will cross over $s(x)$. So, every x belonging to X belong to some B_n . So, B_n is going to increase to X . So, now, we observe the property that look at integral of the non-negative simple measurable function $s d\mu$.

(Refer Slide Time: 18:12)

The image shows a hand pointing to a whiteboard with the following handwritten text:

$$\int s d\mu = \lim_{n \rightarrow \infty} \int_{B_n} s d\mu$$

$$\leq \lim_{n \rightarrow \infty} \int_{B_n} s_n d\mu$$

$$\leq \lim_{n \rightarrow \infty} \int s_n d\mu$$

$$= \int f d\mu.$$

Below this, there is an implication symbol \Rightarrow followed by the inequality:

$$\int s d\mu \leq \int f d\mu, \quad 0 \leq s \leq f$$

In the bottom left corner of the whiteboard, there is a small logo for NPTEL.

So, that we can write it as limit integral n going to infinity integral over B_n of $s d\mu$. So, this is because s_n is increasing sequence s_n an increase is to B_n is an increasing sequence of sets B_n incases is to X and the integral over a set is a measure. So, keep in mind that the integral of a nonnegative simple measurable function over a set e gives you a measure. So, that measure μ of that measure at B_n we will go to that value at x . So, that is same as a in that integral $s d\mu$ is limit of integral s over b and $d\mu$.

Now on B_n we know that on B_n s_n is bigger the x . So, let us use that fact. So, this is less than or equal to limit n going to infinity integral over B_n of $s_n d\mu$. So, that is the nonnegative simple function one or non-negative simple measurable function is less than

other than the integral of one will be less than the other. And now this is integral s_n over B_n . So, if you replace that set B_n by the whole space this will still be less than or equal to limit n going to infinity integral over the whole space x of $s_n d\mu$. So, and that is equal to integral $f d\mu$. So, that proves that integral of $s d\mu$ is less than or equal to integral of $f d\mu$. So, implies that integral $s d\mu$ is less than or equal to integral $f d\mu$ whenever s is less than f and s is nonnegative simple measurable function. So, that proves this property that if f is a nonnegative simple measurable function, f is a nonnegative measurable function and s is a nonnegative simple measurable functions such that s is less than or equal to f , then the integral of s is less than or equal to integral of f .

(Refer Slide Time: 20:31)

Properties

$$\int f d\mu = \sup \left\{ \int s d\mu \mid 0 \leq s \leq f, s \in \mathbb{L}_0^+ \right\}.$$

- Let $f_1, f_2 \in \mathbb{L}^+$ such that $f_1 \geq f_2$. Then

$$\int f_1 d\mu \geq \int f_2 d\mu.$$
- For $\alpha, \beta \geq 0$ we have $(\alpha f_1 + \beta f_2) \in \mathbb{L}^+$ and

$$\int (\alpha f_1 + \beta f_2) d\mu = \alpha \int f_1 d\mu + \beta \int f_2 d\mu.$$

NPTEL

©2009 A. Ghosh, IIT Bombay - p. 9/13

And now as a consequence of this let us observe the property that integral of $f d\mu$ which we defined as the limit of integrals of $s_n d\mu$ for any sequences s_n , can also be represented as supremum over of integrals $s d\mu$ where s is less than or equal to f , and f is s is a nonnegative simple measurable function. So, let us prove this property that. So, let us call.

(Refer Slide Time: 21:01)

Let $\beta = \sup \left\{ \int s \, d\mu \mid 0 \leq s \leq f, s \in \mathbb{L}^+ \right\}$

To show $\beta = \int f \, d\mu$.

2nd case $\int f \, d\mu = +\infty$,
 $f \in \mathbb{L}^+$, $\exists s_n \in \mathbb{L}^+$, $s_n \uparrow f$
 $\int s_n \, d\mu \rightarrow \int f \, d\mu = +\infty$

$\forall N, \exists n_0$ s.t. $\int s_{n_0} \, d\mu \geq N$
 $s_{n_0} \leq f$

Let us define beta to be the supremum of integral of nonnegative simple measurable function $s \, d\mu$, where 0 is less than or equal to the nonnegative simple measurable function s less than or equal to f . So, let us call this. So, we want to show that integral $f \, d\mu$ is equal to beta.

So, let us prove that integral of $f \, d\mu$ can also be written as supremum of integral $s \, d\mu$ where s is less than or equal to f . So, to prove this property let us define. So, let beta be equal to supremum of integral $s \, d\mu$, where 0 is less than or equal to s is less than f and s is a non-negative simple measurable function. So, we want to show that beta is equal to integral $f \, d\mu$. So, now, one possibility is in case integral $f \, d\mu$ is equal to plus infinity then we know that f belongs to \mathbb{L}^+ . So, there is a sequence s_n in \mathbb{L}^+ nonnegative simple measurable functions s_n increasing to f and integral $s_n \, d\mu$ converging to integral $f \, d\mu$, but now in this case we know this is equal to plus infinity; that means, for every positive integer n there exists some n_0 such that integral $s_{n_0} \, d\mu$ will be bigger than or equal to n because this number is going to converge to infinity.

So, this must exceed every n . So, there is n_0 and this s_{n_0} is less than or equal to f . So, we have found a nonnegative simple measurable function s_{n_0} less than or equal to f such that its integral is bigger than or equal to n so that implies that the supremum beta must also be bigger than or equal to n .

(Refer Slide Time: 23:26)

Handwritten mathematical derivation on a whiteboard:

$$\Rightarrow \beta = +\infty$$
$$\beta = +\infty = \int f d\mu.$$

In case $\int f d\mu < +\infty$, $\int s_n d\mu \rightarrow \int f d\mu$

$\forall \epsilon > 0$, $\exists n_0$ such that

$$\int f d\mu - \int s_{n_0} d\mu < \epsilon$$
$$\int f d\mu \leq \int s_{n_0} d\mu + \epsilon \leq \beta + \epsilon$$
$$\Rightarrow \int f d\mu \leq \beta.$$

So, this implies that the supremum beta is bigger than or equal to n for every n and hence that implies beta is equal to plus infinity. So, in the case integral f d mu is equal to plus infinity that implies beta is also equal to plus infinity. So, that is beta is equal to plus infinity is equal to integral f d mu.

So, now let us look at the case when this integral is finite. So, in case integral f d mu is finite; that means, and we know that integral s_n d mu convergence to integral f d mu. So, for every epsilon bigger than 0, there is some n_0 such that integral f d mu minus integral s_{n_0} d mu is less than epsilon and; that means, integral f d mu is less than or equal to integral s_{n_0} d mu plus epsilon; and s_{n_0} is one function which is less than or equal to f. So, this is less than or equal to beta plus epsilon. So, integral f d mu is less than or equal to beta plus epsilon and this holds for every epsilon. So, implying integral f d mu is less than or equal to beta.

So, once again ah we have proved that integral f d mu is less than or equal to beta and clearly.

(Refer Slide Time: 25:01)

$$\Rightarrow \beta = \int f d\mu.$$

$$\forall f \in \mathbb{L}^+, \int f d\mu$$

$$f \in \mathbb{L}^+ \Rightarrow s_n \in \mathbb{L}_0^+, s_n \uparrow f$$

$$\lim_{n \rightarrow \infty} \int s_n d\mu = \int f d\mu$$

$$g \in \mathbb{L}^+ \Rightarrow s'_n \in \mathbb{L}_0^+, s'_n \uparrow g$$

$$\lim_{n \rightarrow \infty} \int s'_n d\mu = \int g d\mu$$

Beta is less than or equal to integral $f d\mu$, that is obvious because beta is a supremum overalls nonnegative simple functions $s d\mu$ less than or equal to integral of f . So, beta is the supremum. So, definition beta is the supremum of integral $s d\mu$ where s is less than or equal to f . So, so integral $s d\mu$ is less than or equal to integral f . So, beta is always less than or equal to integral of $f d\mu$. So, hence this implies beta is equal to integral of $f d\mu$. So, that proves another way of defining the integral of a nonnegative simple measurable function, that if f is a nonnegative simple measurable function then its integral can also be defined as the supremum overall integral $s d\mu$ where s is a nonnegative simple measurable function. So, using these two definitions let us prove that various properties of the integral. So, for every function f in L plus we are defined integral $f d\mu$, and now we are going to look at the properties.

So, the first property that we are saying is if f_1 is bigger than f_2 then integral f_1 is bigger than integral f_2 , and that follows from the above definition itself because integral $f_1 d\mu$ integral $f_1 d\mu$ is going to be the supremum over integrals of all nonnegative simple measurable functions s such that s is less than or equal to f_1 and similarly for f_2 it is going to the supremum overall nonnegative simple measurable functions s less than or equal to f_2 , but if s is less than or equal to f_2 and f_2 is less than or equal to f_1 . So, s is going to be less than or equal to f_1 . So, this supremum for f_1 is taken over a larger class and then that of f_2 . So, that supremum is going to be for integral f_1 the supremum

is going to be bigger than or equal to integral over f_2 . So, that follows directly from here.

From the above definition that this integral is supremum over integral of nonnegative simple measurable functions below f . So, as a consequence of this we immediately have this theorem that if f_1 is bigger than f_2 , then integral $f_1 d\mu$ is bigger than or equal to integral f_2 . Next let us look at the linearity property of this integral namely, if α and β are nonnegative real numbers extended real numbers, then αf_1 and βf_2 are in L^+ plus then $\alpha f_1 + \beta f_2$ belongs to L^+ plus, and integral of $\alpha f_1 + \beta f_2$ is equal to α times integral f_1 plus β times integral f_2 . So, to prove that let's. So, f belongs to L^+ implies there is a sequence s_n of nonnegative simple measurable functions s_n increasing to f , and $\lim_{n \rightarrow \infty} \int s_n d\mu$ giving us the integral of $f d\mu$ and similarly g belongs to L^+ implies that there is a sequence let us call it as s'_n of nonnegative simple measurable functions s'_n increasing to g and its limit $\lim_{n \rightarrow \infty} \int s'_n d\mu$, giving us the integral of $g d\mu$.

So, now from these two let us just simply observe that if s_n increases to f then αs_n will increase to αf and similarly $\beta s'_n$ will increase to βg and integral of $\alpha s_n + \beta s'_n$ for nonnegative simple measurable functions is equal to α times integral s_n plus β times integral s'_n . So, combining all these properties will have the required result.

(Refer Slide Time: 29:43)

Handwritten mathematical derivation on a whiteboard:

$$\Rightarrow \alpha s_n \uparrow \alpha f$$

and

$$\lim_{n \rightarrow \infty} \int (\alpha s_n) d\mu = \alpha \left(\lim_{n \rightarrow \infty} \int s_n d\mu \right) = \alpha \int f d\mu.$$

$$\lim_{n \rightarrow \infty} \int (\beta s'_n) d\mu = \beta \int g d\mu$$

$$(\alpha s_n + \beta s'_n) \uparrow \alpha f + \beta g$$

The whiteboard also features a logo in the bottom left corner with the text "RIITEL" and a hand holding a pen at the bottom right.

So, let us write just write it out. So, implies that alpha s_n increases to alpha of f and limit alpha s_n n going to infinity integral d mu will be equal to alpha times limit n going to infinity of integral s_n d mu, because for nonnegative simple measurable functions alpha times s_n is same as alpha times the integral, and that is equal to alpha integral f d mu and similarly limit of n going to infinity of beta s_n prime integral d mu will be equal to beta times integral of g d mu.

On the other hand if you look at the sequence alpha s_n plus beta g_n sorry if you look at the sequence alpha s_n plus beta s_n dash, then this is a sequence of nonnegative simple measurable functions and that increases to alpha f plus beta g by the properties of sequences. So, as a result we will have that the integral s alpha s_n d mu. So, let us write.

(Refer Slide Time: 31:23)

$$\begin{aligned} \lim_{n \rightarrow \infty} \int (\alpha s_n + \beta s_n') d\mu &= \int (\alpha f + \beta g) d\mu \\ &\parallel \\ \lim_{n \rightarrow \infty} \left[\alpha \int s_n d\mu + \beta \int s_n' d\mu \right] & \\ &\parallel \\ \alpha \left(\lim_{n \rightarrow \infty} \int s_n d\mu \right) + \beta \left(\lim_{n \rightarrow \infty} \int s_n' d\mu \right) & \\ &\parallel \\ \alpha \int f d\mu + \beta \int g d\mu & \end{aligned}$$

So, because of this we have the property that the integral alpha s_n plus beta s_n dash d mu limit n going to infinity will be equal to integral of alpha f plus beta g d mu, but integration is linear for non-negative simple measurable functions.

So, this side this nothing, but limit n going to infinity of alpha integral s_n d mu plus beta integral g_n d mu. And now by the properties of limits of sequences this is equal to alpha times limit integral of a s_n d mu plus beta times sorry this not this is a s_n dash. So, beta times limit n going to infinity of integral s_n dash d mu. And this we know is alpha times integral f d mu plus beta times integral g d mu.

So, integral of $\alpha f + \beta g$ is equal to α times integral f plus β times integral of g . So, that proves the property that when α and β are nonnegative extended real numbers, then $\alpha f + \beta g$ belongs to L plus that we are already shown also and now we are claiming that the integral of $\alpha f + \beta g$ is equal to α times integral of f plus β times integral of g . So, that is same as for this.
