**Lecture - 22 A**  
**Lebesgue Integral and its Properties**

Welcome to lecture number 22 on measure and integration. If you recall in the previous lecture we had started looking at the properties of Lebesgue measure and Lebesgue of Lebesgue integrable functions. And we started looking at analyzing when does a function which is Lebesgue integrable on the interval  $a$  to  $b$  and its relation with Riemann integral of the functions on the interval  $a$  to  $b$ . So, let us we had starting looking at the proof of the theorem namely that if  $f$  is a function defined on an interval  $a$  to  $b$  to  $\mathbb{R}$  which is Riemann integrable, then we wanted to show that it is also Lebesgue integrable. And Riemann integral is same as the Lebesgue integral.

So, we will continue the proof of that theorem, and then go on to analyze some more properties of the space of Lebesgue integrable functions on the interval  $a$  to  $b$ . So, today's lecture is going to be mainly concerned with Lebesgue integral and its properties.

(Refer Slide Time: 01:25)

**Properties of  $L_1[a, b]$**

- Let  $f : [a, b] \rightarrow \mathbb{R}$  be a Riemann integrable function. Then  $f \in L_1[a, b]$  and

$$\int f d\lambda = \int_a^b f(x) dx.$$

NPTEL

So, the theorem we wanted to prove was that if  $f$  is a function defined on an interval  $a$  to  $b$  to  $\mathbb{R}$  and it is Riemann integrable, then it is also Lebesgue integrable and the Riemann integral of the function is same as its Lebesgue integral.

(Refer Slide Time: 01:43)

**Properties of  $L_1[a, b]$**

■ **Step 1:**  
There exist sequences  $\{\psi_n\}_{n \geq 1}$  and  $\{\phi_n\}_{n \geq 1}$  of step functions on  $[a, b]$  such that

- (i)  $\{\psi_n\}_{n \geq 1}$  is monotonically increasing and  $\{\phi_n\}_{n \geq 1}$  is monotonically decreasing.
- (ii)  $\phi_n(x) \leq f(x) \leq \psi_n(x)$ , for  $x \in [a, b]$ .
- (iii)

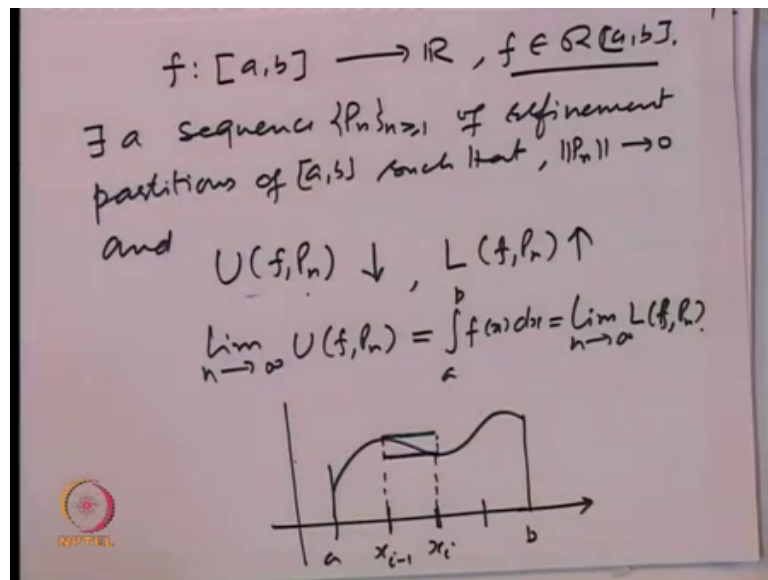

$$\lim_{n \rightarrow \infty} \int_a^b \psi_n(x) dx = \int_a^b f(x) dx = \lim_{n \rightarrow \infty} \int_a^b \phi_n(x) dx.$$

 ©Under K. Prasad, IIT Bombay - p.4/11

So, to prove this theorem we started with those idea that since  $f$  is Riemann integrable, there exist sequences  $\psi_n$  and  $\phi_n$  of step functions on the interval  $a, b$ , such that this sequence  $\psi_n$  is monotonically increasing. And is sequence  $\phi_n$  is monotonically decreasing. And the function  $f$  is between these 2 sequences  $\phi_n$  and  $\psi_n$  for all points  $x$  belonging to  $a, b$ , and the Riemann integral of  $\psi_n$ 's converges to the same value as the Riemann Riemann integral of  $f$  and that is the same as the limit of the integrals Riemann integrals of the step function  $\phi_n$ .

So, let us recall this steps which we had proved last time. So, what we are given is  $f$  is a function defined on a interval  $a, b$  to  $\mathbb{R}$ , and  $f$  is Riemann integrable.

(Refer Slide Time: 02:49)

So, what does the Riemann integrability imply? The Riemann integrability of the function implies the following, namely there exist a sequence  $P_n$  of refinement partitions of the interval  $a$   $b$  such that the norm of these partitions goes to 0, and the upper sums of  $f$  with respect to these partitions that decreases and the upper sums and the lower sums of  $f$  with respect to  $P_n$ 's increases and the common value is the integral.

So, limit  $n$  going to infinity of upper sums is same as integral Riemann integral of  $f$ , and that is same as the limit of the lower sums. So, this is because  $f$  is Riemann integrable. Now let us see what are the upper sums, and what are the lower sums, we need to analyze them a straightly more carefully to look at. So, this is let us draw a picture of the function say the function look like this. So, this is  $a$  and this is  $b$  and we get the partition.

So, with respect to a partition; so, let us say this is the general interval say  $x_{i-1}$  and  $x_i$ . So, in this interval look at what is the smallest value of the function. So, what is the smallest value of the function? That is this, so look at this height. And look at the largest value of the function in that interval. So, largest value of the function is somewhere here. So, look at that height. So, lower sums consist of the areas of this rectangle with height as the blue line. And the upper sums consist of the sums of all the areas which are the green lines.

So, mathematically what this means is the following. So, let us write mathematically what it means. So, mathematically these things mean the following namely. So, look at considering the function. So, let us write. So, consider let us define.

(Refer Slide Time: 06:09)

Define  $P_n = \{a = x_0 < \dots < x_{i-1} < x_i \dots x_n = b\}$

$$M_1 = \sup \{f(x) \mid a \leq x \leq x_1\}$$

$$M_k = \sup \{f(x) \mid x_{i-1} < x \leq x_i\}$$

$$m_k = \inf \{f(x) \mid x_{i-1} < x \leq x_i\}$$

$$m_1 = \inf \{f(x) \mid x_0 \leq x \leq x_1\}$$

$$\phi_n = \sum_{i=2}^n m_i \chi_{(x_{i-1}, x_i]} + m_1 \chi_{[a, x_1]}$$

$$\psi_n = \sum_{i=2}^n M_i \chi_{(x_{i-1}, x_i]} + M_1 \chi_{[a, x_1]}$$

$$\phi_n(x) \leq f(x) \leq \psi_n(x)$$

Define, So let us  $P_n$  is the partition say  $P_n$  is the partition which looks like  $a = x_0 < x_1 < \dots < x_{i-1} < x_i < \dots < x_n = b$ . So, let us say that is the partition. So, define let us say  $M_1$  to be the supremum of the function  $f(x)$   $x$  belonging to  $a$  that is less than or equal to  $x_1$ ,  $x_1$  and let us write  $m_k$  to be the supremum of the function in the general interval. So,  $f(x)$  for  $x$  between  $x_{i-1}$  and  $x_i$ . So, keep in mind here I am taking left open and right close here at the end point is both sides close. So, these intervals are disjoint intervals.

So, what I am doing is in the first part I am looking at this then I am looking at left open right close left open right close left open right close. So, I am partitioning the interval  $a$  to  $b$  according to the partition points  $P_n$  and then looking at the supremums in the respective intervals. Similarly let us write  $m_k$  to be equal to infimum of  $f(x)$  in  $x_{i-1} < x \leq x_i$  and  $M_1$  to be the infimum in the first interval. So, that is  $f(x)$  in  $x_0 \leq x \leq x_1$ . So, what is this value? This  $M_1$  and  $m_k$ s are corresponding to the height which is the green line. So, that is the maximum value or the function in the interval  $x_{i-1}$  to  $x_i$  and the blue ones correspond to small  $m_k$ s.

So, once we had done this mathematically let us define the required functions. So, let us define  $\phi_n$  is the function which is summation  $m_i$  indicator function of  $x_{i-1}$  to  $x_i$   $i$  equal to 2 to  $n$ . And in the first one So, let us put that value as  $M_1$  the indicator function of  $a$  to  $x_1$ . And similarly let us write  $\psi_n$  to be  $\sum_{i=2}^n M_i$  the maximum value in the interval  $x_{i-1}$  to  $x_i$ . And  $M_1$  in the first intervals. So, that is indicator function of  $a$  to  $x_1$ .

So, these are the functions we defined. So, they are corresponding to  $f$ , the function which is  $\phi_n$  small  $\phi_n$  it will look like the minimum values like this, and it will look like  $f$ , it will look like this. And the capital then  $\psi_n$ 's they will look maximum values look like this, and look like this and look like this.

So, quite clearly they are these functions  $\phi_n$  and  $\psi_n$  are step functions, and  $\phi_n$  of  $x$  is less than or equal to  $f$  of  $x$  and less than or equal to  $\psi_n$  of  $x$ . So, as a first step the Riemann integrability of the function  $f$  over the interval  $a$  to  $b$  gives us a sequence of functions  $\phi_n$  and  $\psi_n$ , where each  $\phi_n$  is a step function each  $\psi_n$  is a step function and  $\phi_n$  is less than or equal to  $f$  of  $x$  is less than or equal to  $\psi_n$  of  $x$ . And since we our requirement was that Riemann integrability implies that is a sequence  $P_n$  of partitions is a sequence of refinement partitions. So, that implies that the sequence  $\psi_n$  will be a decreasing sequence and  $\phi_n$  will be an increasing sequence.

So, let us write that observation namely that so, we have  $\phi_n$ 's.

(Refer Slide Time: 11:06)

$\phi_n, \psi_n$  is a step function. 3

$\phi_n \uparrow$  and  $\psi_n \downarrow$

Further

$$\int_a^b \phi_n(x) dx = m_1(x_1 - a) + \sum_{k=1}^n m_k(x_k - x_{k-1}) = L(f, P_n)$$

$$\int_a^b \psi_n(x) dx = M_1(x_1 - a) + \sum_{k=1}^n M_k(x_k - x_{k-1}) = U(f, P_n)$$

and  $\lim_{n \rightarrow \infty} \int_a^b \phi_n(x) dx = \int_a^b f(x) dx = \lim_{n \rightarrow \infty} \int_a^b \psi_n(x) dx$

So, each  $\phi_n \psi_n$  is a step function  $\phi_n$ 's are increasing and  $\psi_n$ 's are decreasing. And moreover further let us look at the Riemann integral of the function  $\phi_n \times dx$  a to b. So, because  $\phi_n$  is constant on each sub interval of the partition this is nothing but equal to  $M_1$  times the length of the first interval. So, that is  $x_1 - a$  plus the sums of those rectangles. So, that is  $\sum_{k=1}^n m_k (x_k - x_{k-1})$  equal to  $1$  to  $n$ . And similarly the Riemann integral of the can  $\psi_n \times dx$  is equal to capital  $M_1$  in the first interval times the width of the interval that is  $x_1 - a$  plus  $\sum_{k=2}^n M_k (x_k - x_{k-1})$  the areas of the other rectangles. So, that is capital  $M_k$  times  $x_k - x_{k-1}$ , right.

So, those are the Riemann integrals and by the definition of the upper and the lower sums this is precisely the lower sum of  $f$  with respect to  $P_n$  and this is precisely the upper sum of the function  $f$  with respect to the partition  $P_n$ . And saying that the function is Riemann integrable implies that the upper sums and the lower sums converge to the same value. So, this and the Riemann integrability implies that the Riemann integral a to b of  $\phi_n \times dx$  limit  $n$  going to infinity is same as the Riemann integral a to b  $f \times dx$  and that is same as the lebesgue same as the Riemann a limit of the upper sums. So, that is limit  $n$  going to infinity the Riemann integral a to b of  $\psi_n \times dx$ .

So, that proves our first step. So, as a consequence of the Riemann integrability of the function  $f$  we have constructed 2 sequences of step functions  $\psi_n$  and  $\phi_n$ , where  $\psi_n$  is monotonically increasing and  $\phi_n$  is monotonically decreasing. And limit are both the integrals of both of them converge to the given integral of  $f$ . Now let us observe at this stage. So, in some sense the step functions and the Riemann integrals are the building blocks for the Riemann integral.

(Refer Slide Time: 14:19).

**Properties of  $L_1[a, b]$**

■ **Step 2:**  
Each of  $\psi_n$  and  $\phi_n$  is Lebesgue integrable and

$$\int_a^b \psi_n(x) dx = \int_{[a,b]} \psi_n d\lambda$$
$$\int_a^b \phi_n(x) dx = \int_{[a,b]} \phi_n d\lambda.$$

 ©Under K. Prasad, IIT Bombay - p.101

Now, let us observe that the lower sum of the function  $f$  with respect to the partition which was the Riemann sum, which was the Riemann integral of  $\phi_n$  is also nothing but the Lebesgue integral of the function  $\phi_n$  with respect to the Lebesgue integral. Because this is this function  $\phi_n$  is a simple function simple measurable function and its integral is nothing but this integral. So, the observation is that for every  $n$  integral  $a$  to  $b$  of  $\phi_n \times dx$  the Riemann integral is same as the Lebesgue integral of the function  $\phi_n$  with respect to the Lebesgue integral over the interval  $a$  to  $b$ .

(Refer Slide Time: 15:07)

$\forall n$

$$\int_a^b \phi_n(x) dx = \int_{[a,b]} \phi_n d\lambda$$
$$\int_a^b \psi_n(x) dx = \int_{[a,b]} \psi_n d\lambda$$

Consider  $\{\psi_n - \phi_n\}_{n \geq 1}$  and apply Fatou's lemma:

$$\int_{[a,b]} \liminf_{n \rightarrow \infty} (\psi_n - \phi_n) d\lambda \leq \liminf_{n \rightarrow \infty} \int_{[a,b]} (\psi_n - \phi_n) d\lambda = 0$$

And this observation is simply by the fact that  $\phi_n$  is a step function. So, hence it is a simple measurable function that its integral is nothing but the value times the Lebesgue measure of the portion on which that value is taken, and that brings here subintervals. So, it is the same as the Riemann integral. And similarly the Riemann integral  $\int_a^b \psi_n dx$  is equal to  $\int_a^b \psi_n d\lambda$ . So, this is the observation which is going to play an important role for us.

So now let us define let us consider the because we have got the observation that the function  $f_n$  the function  $\phi_n$  is always dominated by  $f$  is less than or equal to  $\psi_n$ . So, let us look at the function  $\psi_n - \phi_n$ . So, look at the function. So, consider the sequence  $\psi_n - \phi_n$ . So, look at the sequence of these step functions. These are step functions as well as they are simple measurable functions and they are non negative. So, they are non negative simple measurable functions and by Fatou's lemma. So, we are going to apply Fatou's lemma to this. So, this consider the sequence and apply Fatou's lemma. So, what will that give me? So, that will give me that  $\liminf_n \int_a^b (\psi_n - \phi_n) d\lambda$  limit  $n$  going to infinity  $\int_a^b$ .

So, the Lebesgue integral of the limit inferior is less than or equal to limit inferior of the integral  $\int_a^b (\psi_n - \phi_n) d\lambda$ . So, that is by Fatou's lemma, but let us observe here that  $\int_a^b \psi_n d\lambda - \int_a^b \phi_n d\lambda$ , the limit inferior of that is equal to 0, because integrals the Lebesgue integrals of  $\psi_n$  are same as the Riemann integrals of  $\psi_n$  and Lebesgue integrals of  $\phi_n$  are same as the Riemann integrals of  $\phi_n$  and those Riemann integrals converge to the Riemann integral of  $f$ . So, this right hand side is equal to. So, this is equal to 0. So that means, that the limit inferior of  $\psi_n - \phi_n$  that function is a non negative function and its integral Lebesgue integral is equal to 0. So, that we know implies that the function must be 0 almost everywhere.

(Refer Slide Time: 18:42)

$$\begin{aligned} \Rightarrow \liminf (\psi_n - \phi_n)(x) &= 0 \text{ a.e. } x. \\ \Rightarrow \lim_{n \rightarrow \infty} \psi_n(x) &= \lim_{n \rightarrow \infty} \phi_n(x) \text{ a.e. } x. \\ \text{Since } \phi_n(x) &\leq f(x) \leq \psi_n(x) \\ \Rightarrow \lim_{n \rightarrow \infty} \psi_n(x) &= f(x) = \lim_{n \rightarrow \infty} \phi_n(x) \text{ a.e. } x \\ \Rightarrow f &\text{ is measurable.} \\ \Rightarrow f &\text{ is Lebesgue integrable } (\because f \text{ bdd}) \\ \text{Claim } \int_{(a,b)} f d\lambda &= \int_a^b f(x) dx. ? \end{aligned}$$

So, this implies that limit inferior of the sequence which is  $\psi_n - \phi_n$  must be equal to 0 almost everywhere  $x$ . But we know that  $\psi_n$ 's are increasing and  $\phi_n$ 's are decreasing. So, this limit inferior exists that is that is. So, that implies that limit  $n$  going to infinity of  $\psi_n$ 's is equal to limit  $n$  going to infinity of  $\phi_n$   $x$  almost everywhere  $x$ , but we know since  $f(x)$  is between  $\phi_n$  and  $\psi_n$  of  $x$  this implies along with the earlier effect this implies that limit  $n$  going to infinity of  $\psi_n$   $x$  must be actually equal to  $f(x)$  actually equal to limit  $n$  going to infinity of  $\phi_n$  of  $x$  for almost all  $x$ .

So, this must happen, but that implies because each  $\psi_n$  is a measurable function each  $\phi_n$  is a measurable function this implies  $f$  is a measurable. But recall  $f$  was Riemann integrable function, so obviously, it is a bounded function. So, implies that  $f$  is Lebesgue integrable because  $f$  bounded. So, by boundedness of  $f$  every bounded measurable function and all this is define on  $a, b$  which is a finite measure space. So, that must be integrable that we had observed earlier. So,  $f$  is Riemann integrable.

So, only we have to prove now; so, claim. So, that integral  $f d\lambda$  over  $a, b$  is equal to integral  $a$  to  $b$  of  $f(x) dx$ . So, this is the only thing left to be shown. So, we have what we have shown till now is  $f$  is Lebesgue integrable. So, this integral exist and now let us observe one thing not only  $f$  is Lebesgue integrable it is a limit of a sequence of functions  $\phi_n$ 's  $\psi_n$ 's converge to  $f$  of  $x$ . So, the sequence  $\phi_n$  is converge into  $f$  of  $x$ . And  $\psi_n$

$\psi_n$ 's are decrease into  $f$  of  $x$ . So, whichever fact we require you can use. So, let use the fact that  $\psi_n$ 's are limit of  $\psi_n$ 's converge to  $f$  of  $x$  they are decreasing and each  $\psi_n$  is a integrable function. So, we can apply Lévesque dominated convergence theorem to conclude; so, by dominated convergence theorem.

(Refer Slide Time: 22:07)

Handwritten mathematical derivation on a slide:

$$\begin{aligned} \psi_n(x) &\rightarrow f(x) \text{ a.e. } x \\ \psi_n \downarrow, \psi_n &\in L^1[a, b] \\ \text{LDCT} &\implies \int_{[a, b]} f d\lambda = \lim_{n \rightarrow \infty} \int_{[a, b]} \psi_n d\lambda \\ &= \lim_{n \rightarrow \infty} \int_a^b \psi_n(x) dx \\ &= \lim_{n \rightarrow \infty} U(f, P_n) \\ &= \int_a^b f(x) dx. \end{aligned}$$

The slide also features the NPTEL logo in the bottom left corner and a small square symbol in the bottom right corner.

So, since  $\psi_n$  converge to  $f$  of  $x$  almost everywhere  $x$  and  $\psi_n$ 's are decreasing and integrable  $\psi_n$ 's decreasing  $\psi_n$ 's integrable. So, implies by Lévesque dominated convergence theorem that integral of  $f$   $d\lambda$  over  $a$   $b$  must be equal to limit  $n$  going to infinity of the Lebesgue integral of  $\psi_n$   $d\lambda$ . So, that I end that is the observation of  $a$  already made that the Lebesgue integral of the step function  $\psi_n$  is same as the Riemann integral. So,  $n$  going to infinity. So, that is  $a$  to  $b$  of  $\psi_n$   $dx$ .

And this Riemann integral we have observed is the upper sum and which limit is equal to So, this is the limit of the upper sums of  $f$  with respect to  $P_n$  and that converge to integral the  $a$  to  $b$   $f(x)$  the  $dx$ . So, that will prove that integral Lebesgue integral of  $f$  is same as the Riemann integral of  $f$  over  $d\lambda$ . So, that proves the theorem. So, let us go back and recall the proof the what are the first step as a first step in the proof, using the Riemann integrability of the function we construct 2 sequences of step functions  $\phi_n$  and  $\psi_n$ . So, that  $f$  is trapped in between them and the upper sums are nothing but the upper sums are nothing but the Riemann integrals of  $\phi_n$ 's of  $\psi_n$ 's and the lower, lower sums are nothing but the  $\phi_n$ 's So that means, Riemann integral of  $\phi_n$  converge

into the Riemann integral of  $f$  and which is also equal to  $S_0$ , here is an equality similar to the Riemann integral of  $\phi_n$ .

So, that is this construction is purely from the fact that since the function  $f$  is Riemann integrable. And the second observation is that each  $\phi_n$  and  $\psi_n$  being as step function is also measurable and Lebesgue integrable. And the Lebesgue integral of  $\phi_n$  is same as the Riemann integral of  $\phi_n$  and the Lebesgue integral of  $\psi_n$  is same as the Riemann integral of  $\psi_n$ . So, that is the second observation we will break. So, these 2 integrals Riemann integrals of the step functions are same as the Lebesgue integrals.

And now because of the earlier consequence that the Riemann integrals of  $\phi_n$ 's and  $\psi_n$ 's converge to the Riemann integral of  $f$  look at the difference  $\phi_n$  minus  $\psi_n$ .

(Refer Slide Time: 25:19)

**Properties of  $L_1[a, b]$**

■ **Step 3:**  
 $\lim_{n \rightarrow \infty} \psi_n(x) = f(x) = \lim_{n \rightarrow \infty} \phi_n(x)$  a.e.  $x$ ,  
 implying  $f$  is measurable and hence integrable.

$$\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \int_a^b \psi_n(x) dx$$

$$= \lim_{n \rightarrow \infty} \int_{[a,b]} \psi_n d\lambda = \int_{[a,b]} f d\lambda.$$

NPTEL ©David H. Bates, MIT OpenCourseWare 8.021

So, look at that sequence of measurable functions  $\phi_n$  minus  $\psi_n$  that is a measurable non negative measurable function, and an application of Fatou's lemma I will give us that this  $\psi_n$ 's and  $\phi_n$ 's both must converge to the same value and that is  $f$  of  $x$  almost everywhere. So, that will imply that  $f$  is measurable and being a bounded measurable function on a finite measure space it becomes integrable. And now this  $\psi_n$ 's are dominated by  $f$  of  $x$ . So, an application of Lebesgue dominated convergence theorem gives that the Riemann integral of  $f$  is same as the limits of the Riemann integrals of  $\psi_n$ 's which are equal to the Lebesgue integrals of  $\psi_n$  and that dominated convergence theorem gives you that is the Lebesgue integral of  $f$  over  $[a, b]$ .

So, that proves the theorem a completely namely. So, this is a the step we wanted to this was the beginning of our lectures. Namely we wanted to say that to remove the defects of to remove the defects of Riemann integral namely, that the fundamental theorem of calculus may not hold and that the space of Riemann integrable functions may not be complete under what is called the  $L^1$  norm we wanted to extend that the notion of integral from Riemann integrable function to a bigger class.

So, we have constructed here a class of functions on  $[a, b]$  which are called the Lebesgue integrable functions on  $[a, b]$  and we have shown that if the class of Riemann integrable functions is a subset of the class of Lebesgue integrable functions. And the notion of Lebesgue integral extends the notion of Riemann integral beyond the class of Riemann integrable functions. So, that was there is a first step in our extension theory. So, Lebesgue integral is an extension of the Riemann integral.
