Computation of Product Measure – II

(Refer Slide Time: 00:19)

So now we have got E_n decreasing. So, because E_n belongs; so, what we said first thing was that because E_n belongs to \mathcal{P} . So, this is a measurable function. So, that is a property of the set E_n being in the class \mathcal{P} . So, increasing or decreasing is not coming into picture. So, this step will carry over and then if E_n is increasing to E .

(Refer Slide Time: 00:38)

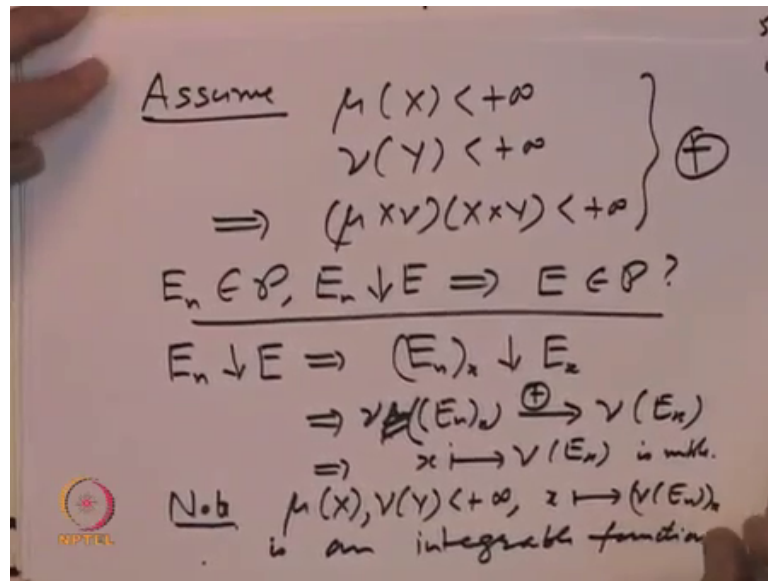

So, now we have got E_n is decreasing to E . So, this thing will change. So, if E_n are decreasing then of course, it is true that the sections $E_n \times$ will be decreasing to the set, the section of the set E at x . So, if the sections $E_n \times$ will decrease through the set E_x . So, that step also will be ok.

Now, we want to say that when E_n decrease to E . So, we want to say that here we use a property that, for the increasing case we said whenever a sequence increasing ν_n of E_n s converge. The corresponding result we know it is not true for decreasing sequences. So, here the proof trying to copy the proof, for the increasing thing will fall down because these steps will not this equation star will not hold, to make this star hold, we have to put extra condition that the measures are finite because if measures are finite then E_n decreasing to E will imply measures converge.

So, if $E_n \mu$ and ν_n are finite say for example, if ν_n is finite. Then E_n sections of each E_n that is a decreasing sequence. So, ν_n of E_n will converge. So, to carry over the proof the similar case, we have to put an extra condition. So, for this claim to hold we have to assume that μ and ν are finite.

(Refer Slide Time: 02:08)

So, let us assume that μ of X is finite and ν of Y is finite, of course that implies $\mu \times \nu$ of $X \times Y$ is finite. So, under this conditions we want to show that if E_n belongs to \mathcal{P} , $E_n \downarrow E \Rightarrow E \in \mathcal{P}$? So, to show that we just now we can repeat the steps.

So, E_n let me just go through the proof again for the decreasing case also, to emphasize where exactly we will be using the finiteness condition. So, E_n decrease to E . So, that implies that the sections $(E_n)_x$ decrease to E_x . So, that implies that ν of $(E_n)_x$ oh sorry a ν of $(E_n)_x$, because $(E_n)_x$ is a subset of b the subset in b . So, this converges to ν of E_x . So, this is the stage we will be using this condition plus. So, under this condition plus that μ and ν are finite, this holds now each E_n belongs to \mathcal{P} . So, each one of them is a measurable function. So, that will imply that $x \mapsto \nu$ of $(E_n)_x$ is measurable.

So, this is a measurable function and we have got ν of $(E_n)_x$ decreases to ν of E_x . So, earlier we use monotone convergence theorem to conclude that ν of $\int ex$ must be limit, but here it is a decreasing sequence. So, we cannot use monotone convergence theorem. Also here, but let us note so here is a observation, note that because μ of X is finite, ν of Y is finite. So, this function ν of $(E_n)_x$ is an integral function. Why is that because it is a decreasing sequence.

(Refer Slide Time: 04:51)

$$v((E_n)_x) \leq v((E_1)_x)$$

and $\int_X v((E_1)_x) d\mu(x) \leq \int_X v(y) d\mu(x) < +\infty$

Dominated convergence theorem
 $(v((E_n)_x) \downarrow v(E_x))$

$$\int_X v(E_x) d\mu(x) = \lim_{n \rightarrow \infty} \int_X v((E_n)_x) d\mu(x)$$

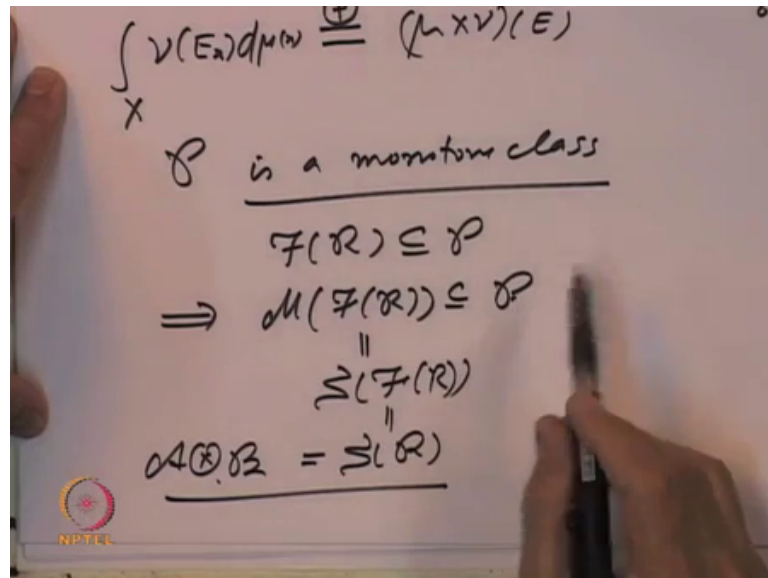

So, let us observe ν of E_n of x for every n , if I look at this non negative function it is less than or equal to ν of E_1 of x and ν of the section E_1 of x integral over x $d\mu$ x right, is less than or equal to ν of E_1 of x is less than or equal to ν of y and So this is integrant is less than ν of y . So, integral of 1 $d\mu$ x is less than μ of x right. So, which is finite; so, ν of E_1 of x is a integral function on the measure space y b ν and each ν of E_n of x is less than or equal to. So, each ν of ν E_n of x is integral.

So, we can apply a dominated convergence theorem. So, dominated convergence theorem applied to the fact that, ν of E_n of x is a sequence of non negative integral functions and they are decreasing to the integral to the function ν of E_x . So, this is also a integral. So, implies by dominated convergence theorem and this observation that the function ν of E_x $d\mu$ x over x , is this function is integral and its integral is nothing but the limit n going to infinity of integrals ν of E_n of x $d\mu$ x . So, for the decreasing sequence the proof differs in both the steps, first of all when we want to say that E_n of r are decreasing the sections decrease.

So, the finiteness conditions allow us to say that ν of E_x is a limit of these functions and that implies that this is a measurable function. So, finiteness says and this function is measurable because of this fact and in fact, the finiteness conditions says this is a sequence of integral functions decreasing to the function this. So, dominated convergence theorem can be applied and that gives us this limit is equal to. So, ν of E_x

integration with respect to μ is limit of and now the proof is as before this E_n be being in the collection \mathcal{P} . So, this integral is nothing, but measure of $\mu \times \nu$ of the set E_n . So, that is limit n going to infinity of measures of the sets E_n and once again E_n s are decreasing to E and $\mu \times \nu$ is a finite measure. So, that will imply so this is equal to $\mu \times \nu$ of E , again using the fact that μ and ν are finite.

(Refer Slide Time: 07:58)

So, we get the conclusion, that again using finiteness condition namely that the integral ν of ν over X is equal to $\nu(X)$. So, we have already shown it is the class \mathcal{P} is closed under increasing sequences, now we have shown it is closed under decreasing sequences. So, \mathcal{P} is a monotone class. So, that proves that \mathcal{P} is a monotone class. So, as a consequence of the fact that \mathcal{P} is a monotone class, the consequence of this would be namely that we already have $\mathcal{F}(\mathcal{R})$ is inside the class \mathcal{P} and \mathcal{P} is a monotone class. So, that will imply that the monotone class generated by $\mathcal{F}(\mathcal{R})$ will also be inside \mathcal{P} .

But this is nothing, but the sigma algebra, generated by the class \mathcal{R} of rectangles or same as the sigma algebra generated by rectangles and that is same as the product sigma algebra. So, that will prove that the product sigma algebra is equal to \mathcal{P} , namely that the required conditions hold for the corresponding.

(Refer Slide Time: 09:29)

The slide is titled "Product of measures" in yellow text on a dark blue background. The main text is white and describes a step in a proof. It states that \mathcal{P} is a monotone class, which implies that the monotone class $\mathcal{M}(\mathcal{F}(\mathcal{R}))$ is contained within \mathcal{P} . It further explains that $\mathcal{M}(\mathcal{F}(\mathcal{R}))$ is equal to the σ -algebra $\mathcal{A} \otimes \mathcal{B}$ generated by $\mathcal{F}(\mathcal{R})$, and concludes that $\mathcal{A} \otimes \mathcal{B} \subseteq \mathcal{P}$. The NPTEL logo is visible in the bottom left corner.

Product of measures

Step 2:
 \mathcal{P} is a monotone class,
implying

$$\mathcal{M}(\mathcal{F}(\mathcal{R})) \subseteq \mathcal{P},$$

where $\mathcal{M}(\mathcal{F}(\mathcal{R}))$ is the monotone class
generated by $\mathcal{F}(\mathcal{R})$.

$\mathcal{M}(\mathcal{F}(\mathcal{R}))$ being equal to the σ -algebra
generated by $\mathcal{F}(\mathcal{R})$, i.e., $\mathcal{A} \otimes \mathcal{B}$,
hence $\mathcal{A} \otimes \mathcal{B} \subseteq \mathcal{P}$. ■

So, that proves a step 2 namely, that \mathcal{P} is a monotone class and that implies that the monotone class generated by \mathcal{F} of \mathcal{R} is inside \mathcal{P} and hence that will prove that monotone class generated by \mathcal{F} of \mathcal{R} is a algebra. So, the monotone class generated by the algebra, is precisely the sigma algebra generated by \mathcal{E} . So, $\mathcal{A} \otimes \mathcal{B}$ will be inside the class \mathcal{P} and hence everything is inside. So, $\mathcal{A} \otimes \mathcal{B} \subseteq \mathcal{P}$.

So, this is a theorem where we have used very sensibly, the fact that when μ and ν are finite in that case, we can extend that argument of the increasing to the case of decreasing also. This also illustrates the technique the monotone class sigma algebra technique. So, we have proved the theorem required claim, that \mathcal{P} is a monotone class under the conditions μ and ν are a finite.

So, now with the usual arguments one can extend it to the case when it is sigma finite.

(Refer Slide Time: 10:38)

Product of measures

proof step 2:

- Let $E = A \times B \in \mathcal{R}$. Then

$$\nu(E_x) = \nu(B)\chi_A(x) \quad \forall x \in X,$$

$$\mu(E^y) = \mu(A)\chi_B(y) \quad \forall y \in Y.$$

implying

$x \mapsto \nu(E_x)$ and $y \mapsto \mu(E^y)$
are measurable functions,

So, let us see that, but before doing that let me just go through the proof of the step 2 again, to illustrate the basic facts. So, the first thing we looked at was if E is a product set A cross B . So, I am just revising the proof of step 2 to highlight the important points in the proof. So, A cross B belongs to \mathcal{r} is a rectangle then ν of E_x . So, that is the first step, the showing that \mathcal{r} is the class in \mathcal{r} will include a rectangles. So, there we use the fact that, if you take a set which is a rectangle. Then intersection is nothing, but either the set A or the set B or the empty set according to the point x or y .

So, ν of E_x is thing, but ν of B times the indicator function of x because if x does not belong to A then this is 0 and the section is just B and similarly μ of E^y is μ of A times the indicator function of y . So, these 2 facts prove that, x going to ν of E_x and y going to μ of E^y for rectangles are measurable functions and if we integrate because this.

(Refer Slide Time: 11:52)

Product of measures

and

$$\int_X \nu(E_x) d\mu(x) = \mu(A)\nu(B) = \int_Y \mu(E^y) d\nu(y).$$

Thus $\mathcal{R} \subseteq \mathcal{P}$.

Next, for $E_1, E_2 \in \mathcal{P}$ with $E_1 \cap E_2 = \emptyset$,

$$(E_1)_x \cap (E_2)_x = \emptyset \text{ and } (E_1 \cup E_2)_x = (E_1)_x \cup (E_2)_x.$$

Hence

$$\nu((E_1 \cup E_2)_x) = \nu((E_1)_x) + \nu((E_2)_x).$$

So, integral of ν will be equal to ν of B into ν of A. So, that is the product measure of the product set A cross B. So, that says the rectangles are inside. So, that is the straight forward argument, which says rectangles comes inside a \mathcal{P} . Showing that \mathcal{P} is a σ -algebra under finite disjointed unions is also a straight forward because that follows from the fact that, if E_1 and E_2 are 2 sets in the class \mathcal{P} which are disjointed, then the sections are disjointed of these 2 sets.

So, and the sections of the union is equal to union of the sections. So, as a consequence of this the ν of the section of the union. So, $(E_1 \cup E_2)_x$ section at x ν of that is addition, ν of $(E_1)_x$ plus ν of $(E_2)_x$ because the sections are disjoint and E_1 and E_2 both belong to \mathcal{P} , imply these 2 are measurable functions and hence the sum of measurable functions is measurable. So, this becomes measurable. So, that is a straight forward proof of the fact that if E_1 and E_2 belong to \mathcal{P} , then even intersection and their disjoint, then the union also belongs to \mathcal{P} and finally look at the integral.

(Refer Slide Time: 13:09)

Product of measures

- Thus $x \mapsto \nu((E_1 \cup E_2)_x)$ is measurable and
$$\begin{aligned} \int_X \nu((E_1 \cup E_2)_x) d\mu(x) &= \int_X [\nu((E_1)_x) + \nu((E_2)_x)] d\mu(x) \\ &= (\mu \times \nu)(E_1) + (\mu \times \nu)(E_2) \\ &= (\mu \times \nu)(E_1 \cup E_2). \end{aligned}$$
- Similarly, $y \mapsto \mu((E_1 \cup E_2)_y)$ is measurable and
$$\int_Y \mu((E_1 \cup E_2)_y) d\nu(y) = (\mu \times \nu)(E_1 \cup E_2).$$

So, integral of nu of the section of the union because that splits into 2 parts. So, nu of E 1 union E 2 is nu of E 1 x plus nu of E 2 x with respect to mu.

So, the internal splits into 2 parts. So, that is mu cross nu of E 1 because E 1 belongs to p and this is mu cross nu of E 2 because E 2 belongs to p and now using the fact that mu cross nu is a measure that gives us this equal to mu cross nu of E 1 union E 2 and the similar thing will work for the y sections. So, proving that rectangles are inside the class p and p is closed under finite disjoint unions, is rather straightforward computation.

(Refer Slide Time: 14:01)

Product of measures

Hence \mathcal{P} is closed under finite disjoint unions.

- Finally, to show that \mathcal{P} is a monotone class, first assume that both μ and ν are finite.

For $E_n \in \mathcal{P}, n \geq 1$, with $E_n \subseteq E_{n+1} \forall n$ and $E = \bigcup_{n=1}^{\infty} E_n$,

$$(E_n)_x \subseteq (E_{n+1})_x \text{ and } (E_n)_y \subseteq (E_{n+1})_y.$$

implying

The problem arises, when we want to show that \mathcal{p} is a monotone class. So, there we first assume that μ and ν are finite. So, once μ and ν are finite, we want to show it is closed under increasing union and decreasing intersections.

So, take a sequence of sets E_n which is increasing. So, a simple fact that if E_n are increasing the sections are increasing, μ and ν being measures imply μ of the sections E_n we will converge to μ of E .

(Refer Slide Time: 14:39)

Product of measures

$\{\nu((E_n)_x)\}_{n \geq 1}$ and $\{\mu((E_n)^y)\}_{n \geq 1}$
are increasing sequences of nonnegative measurable functions.

Hence, $\lim_{n \rightarrow \infty} \nu((E_n)_x) = \nu(E_x)$ and
 $\lim_{n \rightarrow \infty} \mu((E_n)^y) = \mu(E^y)$.

 NPTEL

So, μ of E_x and ν of E_y are limits of measurable functions. So, they become a measurable. So, straight forward till now no finiteness condition has been used. So, this is true whenever μ and ν are any 2 measures but for the decreasing part, where we will need the finiteness condition. So, for the increasing part everything goes straight by a monotone convergence theorem, application gives you ν of E_x is limit of that and that is equal to the product measure and everything is right.

(Refer Slide Time: 15:12)

Product of measures

- Since $E_n \in \mathcal{P} \forall n \geq 1$,

$$\int_X \nu((E_n)_x) d\mu(x) = (\mu \times \nu)(E_n)$$
$$= \int_Y \mu((E_n)^y) d\nu(y).$$

So, let us look at the part where we find the difficulty arises.

(Refer Slide Time: 15:20)

Product of measures

- Similarly, if $E_n \in \mathcal{P}$ and $E_n \supseteq E_{n+1} \forall n \geq 1$, using the fact that μ, ν and $\mu \times \nu$ are finite, we show $\bigcap_{n=1}^{\infty} E_n \in \mathcal{P}$, the main step being

$$\lim_{n \rightarrow \infty} \nu((E_n)_x) = \nu(E_x), \quad \lim_{n \rightarrow \infty} \mu((E_n)^y) = \mu(E^y)$$
$$\lim_{n \rightarrow \infty} (\mu \times \nu)(E_n) = (\mu \times \nu)(E),$$

So, difficulty arises, when we want to show that if E_n belongs to \mathcal{P} and E_n are decreasing, then the set E which is the intersection of E_n also belongs to \mathcal{P} . So, here the main step is to conclude that, ν of $E_n \times$ is equal to ν of E_x . So, for that we need finiteness condition because whenever sets a sequence of sets is decreasing to a set, then measure of the sets need not converge to measure of the limiting set unless the measures are finite. So, finiteness condition will give us that and then instead of monotone

convergence theorem, we can apply the dominated convergence theorem to conclude that $\int \mu \times \nu$ of E_n is equal to corresponding integral.

(Refer Slide Time: 16:07)

Product of measures

Thus \mathcal{P} is a monotone class when μ, ν are finite measures.

In the general case, usual σ -finite arguments apply.

μ and ν are σ -finite, imply

$$X = \bigcup_{j=1}^{\infty} A_j \text{ and } Y = \bigcup_{i=1}^{\infty} B_i,$$

where $\forall i, j, A_i \in \mathcal{A}, B_j \in \mathcal{B}$ with $\mu(A_i) < +\infty$ and $\nu(B_j) < +\infty$.

 NPTEL

So, that will prove that μ and ν being finite \mathcal{P} is a monotone class, but still we are not concluded the proof for the general case. So, for the case one can apply the usual sigma finiteness criteria, namely whenever 2 measure the sigma finite the whole space can be cut up into finite number, countable a disjointed pieces each of finite measure and on each the result holds. So, put them together to get the result holds for the whole space. So, let us see the argument how it works because μ and ν are sigma finite. So, X can be decomposed into a disjointed union of sets A_i and Y can be decomposed into a union of sets B_j . Such that a disjoint union such that, μ of each A_i is finite and ν of each B_j is finite.

(Refer Slide Time: 17:06)

Product of measures

Then

$$(\mu \times \nu)(A_i \times B_j) < +\infty \quad \forall i, j.$$

For $E \in \mathcal{A} \otimes \mathcal{B}$, by the earlier discussion, we have $\forall i, j$

$$\begin{aligned} \int_X \nu((E \cap (A_i \times B_j))_x) d\mu(x) \\ &= (\mu \times \nu)(E \cap (A_i \times B_j)) \\ &= \int_Y \mu((E \cap (A_i \times B_j))^y) d\nu(y). \end{aligned}$$

So, using that we can write down that $\mu \times \nu$ of $A_i \times B_j$ is finite because this is nothing, but μ of A_i times ν of B_j . So, as a consequence on each of these pieces our earlier results hold. The \mathcal{p} was a monotone class. So, let us see how that is used to prove for a general set E in $\mathcal{A} \otimes \mathcal{B}$, for a set in the sigma algebra $\mathcal{A} \otimes \mathcal{B}$. Note that the integral of the measure ν of $E \cap (A_i \times B_j)_x$ $d\mu(x)$ because each ν of each of the sets has got a finite measure right.

So, we are applying the earlier result on the piece $A_i \times B_j$. So, for every i and j using the earlier case, we have that the integral over x of the x sections of $E \cap (A_i \times B_j)$ is nothing, but $\mu \times \nu$ of $E \cap (A_i \times B_j)$ and that is equal to the μ integral of the y sections of the corresponding sets. So, this step follows basically from the fact that $\mu \times \nu$ of $A_i \times B_j$ is finite and for any set E , $E \cap (A_i \times B_j)$ is finite. So, this earlier case gives us the result and now we have to only sum both sides with respect to i and j .

(Refer Slide Time: 18:34)

Product of measures

Thus

$$\begin{aligned} & (\mu \times \nu)(E) \\ &= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} (\mu \times \nu)((A_i \times B_j) \cap E) \\ &= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_X \nu((E \cap (A_i \times B_j))_x) d\mu(x) \\ &= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_Y \mu((E \cap (A_i \times B_j))_y) d\nu(y). \end{aligned}$$

So, let us look at $\mu \times \nu$ of E , is equal to because the whole space is equal to a μ in our I and J , of the rectangles $A_i \times B_j$ that is a partition. So, $\mu \times \nu$ of E can be written as, using countable additivity of the measure $\mu \times \nu$. As summation over I summation over J $\mu \times \nu$ of the pieces $A_i \times B_j$ and now for each one of this piece we know the result holds.

So, I can write this as an integral of the x sections or as integrals of the y section. So, this term $\mu \times \nu$ of $A_i \times B_j \cap E$, is equal to this integral or this integral because of the fact that for the finite case the result holds and now using the fact that if you look at the section $E \cap (A_i \times B_j)$ of x this section is nothing, but μ of $E_x \times A_i$.

(Refer Slide Time: 19:43)

Product of measures

- Also,

$$(E \cap (A_i \times B_j))_x = E_x \cap B_j \text{ if } x \in A_i,$$

$$= \emptyset, \text{ otherwise.}$$
- Thus, by monotone convergence theorem,

$$\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_X \nu((E \cap (A_i \times B_j))_x) d\mu(x)$$

$$= \sum_{j=1}^{\infty} \left(\sum_{i=1}^{\infty} \int_{A_i} \nu(E_x \cap B_j) d\mu(x) \right)$$

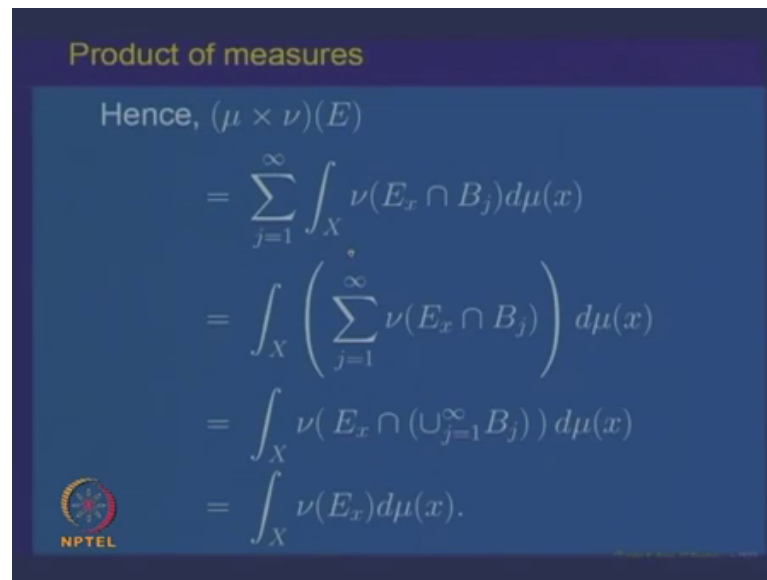

So, this is a the small observation, that you look at set E and take its piece inside the rectangle A i cross B j and take its section ok.

So, this section is going to be equal to the section of E intersection with B j. Of course, if x belongs to E j and the facts does not belong to E j then there is not going to be any intersection. So, this is going to be empty set. So, this is a observation and that observation can be used in this part that, if x does not belong to A i then this thing is going to be 0. So, using that we can write that sum. So, this sum which was integral over x of E intersection this can be written as. So, this set is nothing, but nu of E x intersection B j because that is the only place where the section appears when x belongs to A i. So, this is integral over A i of mu ex intersection B j.

So, this integral is equal to this because of this fact and now the summation over I means that this integral is over x.

(Refer Slide Time: 20:59)

Product of measures

Hence, $(\mu \times \nu)(E)$

$$= \sum_{j=1}^{\infty} \int_X \nu(E_x \cap B_j) d\mu(x)$$
$$= \int_X \left(\sum_{j=1}^{\infty} \nu(E_x \cap B_j) \right) d\mu(x)$$
$$= \int_X \nu(E_x \cap (\cup_{j=1}^{\infty} B_j)) d\mu(x)$$
$$= \int_X \nu(E_x) d\mu(x).$$

NPTEL

So, this summation you can transform into integral over x and now you can interchange the 2 integral and the summation again. You will be using fact here that this is a integral which depends on j . So, you can push it out and take it inside, basically you will be applying implicitly a monotone convergence theorem to say that this is equal to I . Can take the integral sign x right and because this is a sequence of a functions which are non negative measurable and So on.

So, here is an application of monotone convergence theorem, which helps you to interchange summation and the integral sign. So, summation goes inside and now summations over B_j are disjoint. So, that gives you over the whole space y . So, that is just E_x . So, you get that $\mu \times \nu$ of E is equal to the integral of the section ν of E_x $d\mu(x)$. So, you see that almost every step, we are using sum theorem at the other to justify the facts. So, this is the case for the x sections and the similar result will hold for a y sections.

(Refer Slide Time: 22:11)

Product of measures

- Similarly,

$$\begin{aligned}(\mu \times \nu)(E) &= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_Y \mu((E \cap (A_i \times B_j))^y) d\nu(y) \\ &= \int_Y \mu(E^y) d\nu(y),\end{aligned}$$

So, that will prove that $\mu \times \nu$ is also equal to integral over the y sections and that will complete the proof of the fact that, one can reduce the result in the case of a sigma finite. So, from finite to sigma finite is almost a straight forward, in the sense that we split the whole space into countable number of pieces a finite measure.

So, on each piece we apply and then sum it up to go back to the original piece. So, we have proved the theorem namely, a how to compute the measure of a product Set.

(Refer Slide Time: 22:48)

Product of measures Remark:

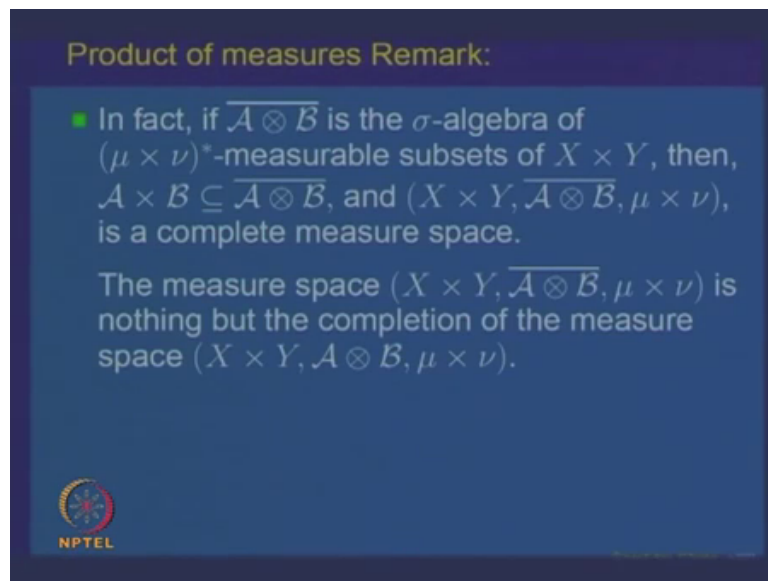

- The product measure space $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ need not be a complete measure space even if the measure spaces (X, \mathcal{A}, μ) and (Y, \mathcal{B}, ν) are complete.
- For example, if $A \subset X, A \notin \mathcal{A}$ and $\emptyset \neq B \in \mathcal{B}, \mu(B) = 0$, then $(\mu \times \nu)^*(A \times B) = 0$, but $A \times B \notin \mathcal{A} \otimes \mathcal{B}$.

So, let us observe one thing here namely, even if we start with measure spaces (X, \mathcal{A}, μ) and (Y, \mathcal{B}, ν) to be complete. The product measure space which we have denoting by $X \times Y, \mathcal{A} \times \mathcal{B}, \mu \times \nu$ need not be complete. Because how do you do we get this measure $\mu \times \nu$ on $X \times Y$. we looked at the product $\mu \times \nu$ on rectangles and extended it and defined the outer measure via that and then looked at the measurable sets $\mu \times \nu$ and that included this sigma algebra.

So, this $\mathcal{A} \times \mathcal{B}$ the product sigma algebra is not the sigma algebra with respect to which of all $\mu \times \nu$ measurable sets. So, it may not be complete. So, for example, you can take any set A in X such that A does not belong to the algebra \mathcal{A} and take any non empty set B of measure 0, then the outer measure of $\mu \times \nu$ will be equal to 0 because $\nu(B)$ is equal to zero. But the rectangle $A \times B$ does not belong to product sigma algebra because A does not belong to \mathcal{A} . So, in case one wants to look at the completion of this so, that is possible.

(Refer Slide Time: 24:12)

So, if you look at the sigma algebra $\overline{\mathcal{A} \times \mathcal{B}}$ and denote that to be the sigma algebra $\mu \times \nu$ measurable subsets the product space. Then of course, the product sigma algebra is inside it and that will be a complete measure space. So, you can say that $X \times Y$ and $\mu \times \nu$ measurable sets, as before is the completion of product measure space $X \times Y, \mathcal{A} \times \mathcal{B}, \mu \times \nu$. So, this is just a small observation

which we should keep in mind that, the product sigma algebra which is a sigma algebra generated by the rectangles need not be giving you a complete a measure space.

(Refer Slide Time: 24:56)

The slide is titled "Product of measures" in yellow text on a dark blue background. It contains a bullet point in green text: "Further, for $E \in \overline{\mathcal{A} \otimes \mathcal{B}}$ the functions $x \mapsto \nu(E_x)$ and $y \mapsto \mu(E^y)$ are measurable and". Below this is a mathematical equation:
$$\int_X \nu(E_x) d\mu(x) = (\overline{\mu \times \nu})(E) = \int_Y \mu(E^y) d\nu(y)$$
 At the bottom left of the slide is the NPTEL logo, which consists of a circular emblem with a book and a lamp, and the text "NPTEL" below it.

However, one can always complete it and the corresponding result holds for sets in A times B that is a small technical result. Which one can prove that, we had proved this result for sets in the product sigma algebra namely you can integrate the sections and get back the product measure. So, this also applies to any set E in the product sigma algebra; that means, in the completion space also the corresponding a result holds. So, this is the way we can compute the product measure of a set in the sigma algebra. I want to go about to an interpretation of this result, which leads to a very important a result in integration of product spaces. So, what we had was the result namely.

(Refer Slide Time: 25:55)

$$E \in \mathcal{A} \otimes \mathcal{B}$$

$$\int_X \nu(E_x) d\mu(x) = \int_Y \mu(E_y) d\nu(y)$$

$$(\mu \times \nu)(E) = \int_{X \times Y} \chi_E d(\mu \times \nu)$$

$$\int_X \left(\int_Y \chi_E(x,y) d\nu(y) \right) d\mu(x) = \int_Y \left(\int_X \chi_E(x,y) d\mu(x) \right) d\nu(y)$$

So, what we had shown is for every set E , in the product sigma algebra \mathcal{A} times \mathcal{B} we can take its section with respect to every point x that gives us a set in the sigma algebra \mathcal{B} . So, we can define ν of that and that becomes we show it is a non negative measurable function. So, I can integrate this over x with respect to μ , on the other hand I can also take the section of E with respect to every point y and then take gets measure. We showed that this sections belong to \mathcal{A} , take it is measure μ of E_y and we showed that that is a non negative measurable function and I can integrate it over y $d\mu$ of y right and we showed that, these 2 are equal. In fact, both of them are equal to the product μ cross ν of E .

But a simple observation that the measure of a set is the integral of the indicator functions. So, what is this, I can write it as integral over x this μ of E_x , I can write it as integral over y of the indicator function of E_x , $d\nu$ of y and similarly this thing. I can write it as integral over y μ of E_y . So, that way I can write as integral of over x of the indicator function of E_y $d\nu$ of y and then we should have $d\mu$ of x . So, integral sorry this is E_y . So, this is $d\mu$ of y . So, this is E_y . So, there should be $d\mu$ of x and then $d\nu$ of y ok.

And this product thing, I can write as integral over x cross y of the indicator function of E , the product measure μ cross ν . So, we get a integral representation of this result namely that, I can take the indicator function of the set E . So, but note that this function the indicator function of E_x is nothing but, see this is nonzero when y belongs to E_x ; that means, x comma y belongs to E . So, this is just the indicator function of E_x comma

y. So, and similarly this is also the indicator function of a $E \times Y$. So, everywhere it is indicator function of E . So, what we are saying is look at the indicator function of the set E and integrate with respect to y . So, keep x fix and integrate with respect to y , that depends on x integrate with respect to x or take the indicator function of E , then integrate with respect to x . So, keep y fix. So, that integral depends on y and integrate it over y . So, that is another number that you will get.

And it says both of them are equal to integral of the indicator function of the set E with respect to the product measure $\mu \times \nu$. So, let me just rewrite and show it to you in the form in the slide.

(Refer Slide Time: 29:41)

Integration on product spaces

This can be interpreted as follows:
For every $E \in \mathcal{A} \otimes \mathcal{B}$,

$$\int_{X \times Y} \chi_E(x, y) d(\mu \times \nu)(x, y)$$

$$= \int_X \left(\int_Y \chi_E(x, y) d\nu(y) \right) d\mu(x)$$

$$= \int_Y \left(\int_X \chi_E(x, y) d\mu(x) \right) d\nu(y).$$

 NPTEL

So, what we are saying is the result that we proved just now, for every set E in the product sigma algebra $\mathcal{A} \times \mathcal{B}$. I can rewrite the result in the form of integrals that namely, it is same as saying that the integral of the indicator function of E with respect to the product measure $\mu \times \nu$. Is same as look at the indicator function it is a function of 2 variables, for a this function of 2 variables I can fix an x if I fix an x and vary only y then this indicator function becomes a function of one variable y . So, it says let me integrate this function, indicator function of E for a fixed x with respect to y . So, this integral is can be computed it and this integral depends on x and says that is a measurable function and its integral can be taken with respect to x with respect to the measure μ and that is same as that integral.

And similarly instead of fixing the first variable x , I can fix the second variable as y I can fix this as y . So, then this becomes a function of x , I can integrate it with respect to x . I get a number which depends upon y and that function is integral with respect to y and that integral is also equal to the original one. So, the result of computation of a product measure of a set E in the set A cross B can be written in terms of the integrals, of indicator function over the product set. So, basically this illustrates that to integrate the indicator function which is a function of 2 variables, I can integrate as 1 variable at a time.

So, this is an important result which leads to an important result in integration that given a function of 2 variables, if you want to integrate it with respect to the product measure then this gives a hint then possibly what one can do is fix 1 variable of the 2 variable function. So, it becomes a function of 1 variable integrate it out the 1 variable and then it becomes a function of the other variable, integrate out that variable also you get the integral with respect to the product measure

So, we will prove this in the next lecture. Namely that this result can be extended to non negative measurable functions on product spaces and eventually, it can be extended to integral functions. So, that leads to the important theorems in the theory of integration on product spaces called Fubini's theorems. So, we will continue looking at that in the next lecture.

Thank you.
