Local maxima and minima, continuity test, first derivative test, successive differentiation

(Refer Slide Time: 00:35)

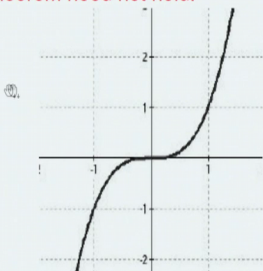

Local maxima/minima

- We looked at the notion of Local maxima/minima of functions.

Theorem

Let $f : (a, b) \rightarrow \mathbb{R}$, $c \in (a, b)$.
If c is a point of local maxima or local minima and $f'(c)$ exist, then $f'(c) = 0$.

- The converse of the theorem need not hold.

 NPTEL ©Inder K. Rana, I. I. T. BombayCalculus for ECM2 / 28

So, let us start recalling our previous lecture. In the previous lecture, we had started looking at the properties of local maxima minima of our functions of one variable in particular we looked at the following theorem namely if f is a function which is defined on an open interval a, b to \mathbb{R} and c is a point in that open interval.

If c is this point which we have in selected in a, b is a point of local maxima or a local minima then f dash of c exists and f of f dash of c exists then f dash of c is equal to 0. So, if 2 conditions are satisfied, namely c is a point of local maxima or minima and the derivative at that point exists, then the derivative must be 0, geometrically that means the tangent must be horizontal and we also pointed out the converse of this theorem need not hold namely the derivative equal to 0 at a point need not imply the function has a local maxima or minima.

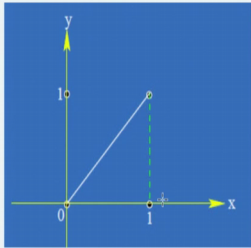

We had given some examples here is the graph of f of x is equal to x cube this graph is on the positive side it is positive it becoming flatter and flatter and terms negative value

for negative values x cube is negative. So, it turns around. So, at 0 the x axis is a tangent to this curve y equal to x cube; what at this point you can; obviously, see that there is no maxima or minima because at all points nearby on the left the values are smaller and all the values of the function at points on the positive side are positive. So, there will be bigger than the value at the function at the point 0. So, this convergence of this theorem need not be true.

(Refer Slide Time: 02:22)

Local maxima/minima

- Theorem holds only for c being an interior point.
If c is an end point, then f can have a local max/min at $x = c$ without derivative being zero.

For example, the function

$$f(x) = x, x \in [0, 1]$$

has local maxima at $x = 1$ and local minimum at $x = 0$ with

$$f'(0^+) = f'(1^-) = 1.$$

NPTEL © Inder K. Rana, I. I. T. Bombay Calculus for ECM 3 / 28

So, that is one observation and secondly the theorem holds only when c is a interior point. So, keep in mind the where the interval is a, b open interval a, b and the function is defined in the open interval a, b . So, this need not hold the conclusion that c is a point of local maxima or minima and the derivative at that point exists.

This need not hold if the interval is having endpoints say for example, let us look at this example f of x is equal to x if x belongs to $0, 1$. So, this function y is y equal to x and this is the graph of the function. So, the function has got 0 at 0 and is one at one. So, if you look at the neighborhood of 0 in the domain of the function on the right side, the values are positives. So, there bigger than 0. So, 0 is a local minima and one is a point of local maximum, but if I look at the derivative of this function on the left or from the right and the derivative is equal to. So, at this point the only possible is to derivative for the function from the left side or and 0 the only possibility is derivative rate of changes the function from the right side both are equal to 1.

So, the derivative is not equal to 0. So, the if condition of saying that the derivative at a point of local maxima or minima should be 0 is valid when we have a domain the point where we are analyzing is in an open interval.

(Refer Slide Time: 04:09)

Note

- Local maxima/minima to occur, it is not necessary that the function has to be differentiable.
- Consider the function $f(x) = |x|, x \in \mathbb{R}$.
- In fact a function can have local maxima/minima at a point without even being continuous at that point.

$$f(x) := \begin{cases} +1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0. \end{cases}$$

Then f has local maximum at $x = 0$, but f is not even continuous at $x = 0$.

NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 4 / 28

So, that was the second observation, we wanted to point out and also look at that we are saying that this is only a necessary condition; that means, a local maxima or minima to occur it is not necessary the function has to be differentiable we are only this theorem only gives you a necessary condition if the derivative exists at that point, but functions can have local maxima or minima without being differentiable. So, let us look at for example, the $f(x) = |x|$ the function $f(x) = |x|$ has got a minimum value at the point $x = 0$, but the function is not differentiable at that point $x = 0$, right.

On the left if you look at on the left of this point $x = 0$ the function is $-x$. So, the derivative is -1 . So, left derivative at the point 0 is -1 and the right derivative at the point $x = 0$ if we are coming from the right side the function is x and the derivative is 1 . So, the function is not differentiable at the point 0 , but still it has a local minimum at the point $x = 0$. In fact, something much stronger can be said here this function is continuous at 0 , but is not differentiable at 0 and as a local minimum at 0 ; even there can we can defined a give examples of functions which can have local maxima or minima at a point without even being continuous at that

point. So, that is also possible for example, let us look at the function $f(x)$ is equal to plus 1 at x bigger than or equal to 0 and equal to 0 if x is less than 0 function as a local maximum at the point 0 the value is 1.

So, for all points in a neighborhood of that point x is equal to 0 the value at the point 0 is bigger than or equal to value at every other point. So, the function has a local maximum at the point x is equal to 0, but f is not even continuous at the point 0 the left limit is 0 where the function at that point and the right limit is equal to 1.

So, this function is not continuous at 0, but still the function has a local maximum at the point x is equal to 0. So, the existence of local maximum or a minimum for a function has nothing to do with this property being continuous or property being differentiable; what we are saying is in terms of continuity or differentiability you can give conditions which ensures that a point is a local maxima or minimum.

(Refer Slide Time: 06:57)

Continuity test for local maximum/minimum

Theorem (Continuity test)

Let $f : (a, b) \rightarrow \mathbb{R}$ and f be *continuous* at $c \in (a, b)$.

(i) If f is increasing in an interval $(c - \delta, c)$ and decreasing in an interval $(c, c + \delta)$, for some $\delta > 0$, then f has a local maximum at c .

(ii) If f is decreasing in an interval $(c - \delta, c)$ and increasing in an interval $(c, c + \delta)$, for some $\delta > 0$, then f has a local minimum at c .

NPTEL (©Inder K. Rana, I. I. T. Bombay)

Calculus for ECM

5 / 28

So, our previous theorem give as necessary condition and let us now state some sufficient conditions which ensure that a point which we are analyzing is a point of local maxima or minima.

So, the theorem is called the continuity test. So, this says let us suppose f is a function on a open interval a, b to \mathbb{R} and it is given to be continuous at the point c belonging to the open interval a, b . So, if f is increasing in an interval in c minus delta to c ; that means, on

the left side of c if the function is increasing and it is decreasing and an interval $c - 2\delta$ to $c + \delta$ which is an interval on the right side of c , then f should have a local maximum at the point c . So, this is the mathematical way of saying that if the function is rising on the left and falling on the right and it is continuous at the point c , then it must have a local maximum at the point c .

So, the geometric visualization that we have of local maximum is translated into this property namely. So, this is a sufficient condition that if function is continuous at the point c on the left of c it is decrease on the left of c it is increasing and on the right of c , it is decreasing then it has a local maximum at c . So, there is a parallel condition similar condition for local minimum which is says at if f is decreasing on the left side of c . So, that is in interval $c - \delta$ to c and is increasing and interval on the right side of the it; that means, in a interval $c - 2\delta$ to $c + \delta$ then it must be local minimum of c .

So, of both this geometric visualizations translated into mathematical concept are true when f is continuous at c right. So, do not make a mistake of an saying that on the left it is increasing on the right it is decreasing. So, it must be a local maximum that happens when you have a condition satisfied that the function is continuous and similarly for decreasing. So, this is what is called the continuity test for increasing and for continuity test for local maximum and local minimum.

(Refer Slide Time: 09:26)

First derivative test for local maximum/minimum

Theorem (First derivative test)
 Let $f : (a, b) \rightarrow \mathbb{R}$ and $c \in (a, b)$ be such that f is continuous at c .

(i) If there some $\delta > 0$, such that $f'(x)$ exists in $(c - \delta, c) \cup (c, c + \delta)$, with
 $f'(x) \geq 0$ for $x \in (c - \delta, c)$ and $f'(x) \leq 0$ for $x \in (c, c + \delta)$,
 then f has a local maximum at c .

(ii) If there some $\delta > 0$, such that $f'(x)$ exists in $(c - \delta, c) \cup (c, c + \delta)$, with
 $f'(x) \leq 0$ for $x \in (c - \delta, c)$ and $f'(x) \geq 0$ for $x \in (c, c + \delta)$,
 then f has a local minimum at c .

 NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 6 / 28

We can also say we have a theorem in terms of the first derivative what is called the first derivative test if we recall we proved that if the derivative of a function in the previous lecture we had proved that if the derivative of function is bigger than 0, then the function is increasing in an interval and similarly if the derivative of a function is less than 0, then the function must be decreasing in that interval.

So, that property together with the previous theorem gives us what is called the first derivative test suppose f is defined on an open interval a, b to \mathbb{R} and c is a point in the open interval a, b such that f is continuous at c . So, continuity is always going to be condition. So, suppose there is a; some δ bigger than 0 such that the derivative exists in an interval around c so, but may not be the at point c . So, this is written mathematically as there exists some δ bigger than 0 such that if you look at the intervals open interval c minus δ to c union the open interval c to c plus δ , then the derivative exists in this interval; that means, at every point on the left of c and on the right of c on this interval the derivative exists. So, that is one part of the condition and second thing is if the f dash of x is bigger than 0 on the interval c minus δ to c and f dash of x is less than or equal to 0 in the part c to c plus δ .

So, that will imply by the previous theorems that if this is. So, then f will be increasing on the left and f will be decreasing on the right. So, that will imply that it has a local maximum at the point c . So, this the first derivative test requires 2 things one first of all the derivative was the function must be continuous at the point c and. Secondly, in a neighborhood of the point c may accepted possibly at the point c , the derivative is bigger than or equal to 0 on the left and less than 0 on the right.

Then it has a local maximum at that point and the second condition similar condition is there for the local minimum that there is a δ bigger than 0 say if that the derivative exist in the neighborhood around c accepted the point c such a neighborhood normally is called a related neighborhood because this is a neighborhood around the point c of length c minus δ on the left and c plus δ on the right and only the point c is omitted from it.

So, from a interval c minus δ to c plus δ if we omit the point c new that a union of 2 disjoint open intervals. So, this is called the related neighborhood of the point c . So, the condition says there is in a related neighborhood of the point c the derivative exists and if

we have derivative is less than or equal to 0 on the left and bigger than 0 on the right. So, that will imply from the derivative conditions that the function is decreasing on the left and increasing on the right. So, it must have a local minimum at that point c . So, this is what is called the derivative test first derivative test for analyzing a point to be a point of local maxima or minima. So, these are this you can these are the sufficient conditions which ensure whether a point is local maxima or minima. So, let us repeat once again if you are able to say that the function is continuous at the point c on the left of c , the derivative is positive on the right of c derivative is negative then it has a local maximum.

Then it has. So, if those conditions are satisfied then it has a local maximum. So, that point will be a point of local maximum and similarly if f is continuous and its derivative exists in the related neighborhood with the property that derivative is less than or equal to 0 on the left and bigger than or is equal to 0 on the right, then it has a local minimum at the point c . So, this theorem can be used to analyze whether a point is a point of local maxima or minima for a given function or not. So, one has to check all these conditions and then draw the appropriate conclusion.

(Refer Slide Time: 14:18)

First derivative test for local maximum/minimum

- **Example**
Consider the function

$$f(x) = (x + 2)|x|, x \in \mathbb{R}.$$

It is continuous everywhere and is differentiable everywhere, except at $x = 0$.

$$f'(x) = 2(x + 1) > 0 \text{ for } x > 0,$$

and

$$f'(x) = -2(x + 1) < 0 \text{ for } x < 0.$$

Thus, f has a local minimum at $x = 0$ by the first derivative test.

NPTEL © Inder K. Rana, I. I. T. Bombay

Calculus for ECM

7 / 28

So, let us look at this function f of x is equal to x plus 2 into mod x ; x belonging to \mathbb{R} now first of all when you look at such a function there is this term mod x coming and we know that modulus of a number x is equal to x if x is bigger than 0 and it is less than x is if x is less than 0.

So, this function is continuous everywhere because it is a product of 2 functions plus 2 which is continuous and mod x is continuous. So, this is a function which is continuous everywhere; let us look at the differentiability of this function it is continuous everywhere except and it is differentiable also everywhere except that the points 0. See if x is not equal to 0, this function is either x plus 2 into x if x is positive and this function is x plus 2 minus x if x is negative and at the point 0, we know mod x is not differentiable. So, this function is not going to be differentiable at mod x that is not the exact reason the reason is if you look at the left derivative and the right derivative for this function; they will turn out to be different. So, to see that let us just analyze because this is the first time we were coming across such an example.

So, let us look at the differentiability of this function at the point.

(Refer Slide Time: 15:51)

The image shows a whiteboard with handwritten mathematical work. At the top, the function is defined as a piecewise function:
$$f(x) = \begin{cases} (x+2)x & \text{if } x \geq 0 \\ (x+2)(-x) & \text{if } x < 0 \end{cases}$$
Below this, the function for $x \geq 0$ is simplified:
$$\text{for } x \geq 0, \quad f(x) = (x+2)x = x^2 + 2x$$
Then, the right-hand derivative at $x=0$ is calculated using the limit definition:
$$f'_+(0) = \lim_{x \rightarrow 0^+} \frac{f(x) - f(0)}{x}$$

$$= \lim_{x \rightarrow 0^+} \left(\frac{x^2 + 2x - 0}{x} \right)$$

$$= 2$$
An NPTEL logo is visible in the bottom left corner of the whiteboard image.

So, f of x the function is equal to x plus 2 into x if x is bigger than or equal to 0 and is equal to x plus 2 into minus x if x is less than or equal to 0. So, for x bigger than or equal to 0 the function is f of x equal to x plus 2 into x, which you can write as x square plus 2 x. So, if I look at the derivative at the point 0. So, what will be the value of the function at 0 is 0. So, what will be the f dash of at 0 and I am coming from the positive sides of plus. So, that will be limit of x going to 0 of f of x minus f of 0 divided by x and x positive.

So, that will be equal to limit x going to 0 and when x is positive the value is x square plus $2x$ of 0 is 0 divided by x . So, that is equal to limit when x cancels. So, it is x plus 2. So, the value is 2. So, the right derivative at the point 0 is 2; let us compute the left derivative of this at the point 0.

(Refer Slide Time: 17:26)

The image shows a hand holding a whiteboard with the following handwritten work:

$$\begin{aligned} \underline{x \leq 0} \\ f(x) &= (x+2)(-x) \\ &= -x^2 - 2x \\ f'_-(0) &= \lim_{\substack{x \rightarrow 0 \\ x < 0}} \frac{f(x) - f(0)}{x} \\ &= \lim_{x \rightarrow 0} \left(\frac{-x^2 - 2x - 0}{x} \right) \\ &= -2 \end{aligned}$$

So, for x less than 0; less than or equal to 0 does not matter because the function is uniquely defined at the point 0 f of x is equal to x plus 2 and the mod x is now minus x . So, it is equal to minus x square plus minus $2x$. So, the f dash of 0; from the coming from the right will be equal to limit x going to 0 f of x minus f of 0 divided by x ; x less than 0.

So, when you put the values. So, limit x going to 0 of when x is negative. So, it is minus $2x$ minus of x square minus $2x$ and at 0 the value is 0 divided by x . So, what will be limit of this; once you cancel out x . So, that is equal to x go to 0. So, it is minus 2. So, when you look at the left limit of the function that is minus 2, you will look at the right derivative at the point 0 that is 2. So, this function is not differentiable at the point 0. So, let us come back to the statement that the for the function f of x is equal to x plus 2 into mod x it is continuous everywhere and it is differentiable also everywhere except at the point x is equal to 0.

So, let us look the derivative of this function on the left side and on the right side. So, derivative when the function is big x is bigger than 0 the function is given by x plus 2

into x . So, what will be the derivative for all points on the right side it will be 2 times x plus 1. So, which is bigger than 0 for all x bigger than 0 and similarly, if I look at or the left side of this function then the function is given by $\text{mod } x$ will be minus x . So, it is minus x plus 2 into minus x . So, that will be minus of $2x$ plus 1 for this is a type of where it should be less than 0. So, this point should be less than right sorry. So, this is for all values x less than 0. So, on the right side the function has positive derivative on the left side the function has negative derivative. So, this implies that f has a local minimum at the point x equal to 0 by the first derivative test.

So, how is the first derivative test applicable at the point x is equal to 0 the function is continuous. So, condition of continuity is satisfied related neighborhood of 0, right, f dash of x is bigger than 0 if x is bigger than 0. So, to the function is rising on the right side and it is less than 0 on the left side. So, it is dropping. So, by the first derivative test the function has a minimum at the point x is equal to 0. So, that is how you will apply the first derivative test by ensuring the continuity of the function at the point that you want to analyze looking at the nature of derivative on the left of that point and on the right of that point at that point the function may not be differentiable that is not required for the first derivative test.

(Refer Slide Time: 21:05)

Successive Differentiation

Definition

Let $I \subseteq \mathbb{R}$ be an interval and $f : I \rightarrow \mathbb{R}$.
 We say f is **twice differentiable** at $c \in I$ if f is differentiable on $(c - \delta, c + \delta)$ for some $\delta > 0$ and the derivative function
 $f' : (c - \delta, c + \delta) \rightarrow \mathbb{R}$
 is differentiable at c .
 In that case we define the second order derivative of f at c to be
 $f''(c) := (f')'(c)$.
 It is also denoted by

$$\frac{d^2 f}{dx^2}(c).$$

NPTEL (© Inder K. Rana, I. I. T. Bombay)
Calculus for ECM
8 / 28

So, let us go a step for that and let us look at what is called second derivative test, but for the second derivative test I want to recall what is called second derivative of a function

and. So, one. So, there is a notion of successive differentiation. So, let us say a function f is defined on an interval I contained and so, as the function domain is a interval and taking real values. So, I is a interval in the real line and f is a function defined on the interval we say f is twice differentiable at a point c . So, it is said to be twice differentiable at a point c which is inside this interval I if f is first of all differentiable in a open interval around the point c in a neighborhood. So, first of all I have this is a condition that f should be differentiable at all points in a neighborhood of the point c . So, what it a neighborhood it is an open interval around the point c of length 2δ . So, it will be $c - \delta$ to $c + \delta$.

So, f should be differentiable in a neighborhood of the point c one and. So, once it is differentiable at every point x in this interval will get f' of x . So, f' is a function now in the inter which is defined in the interval $c - \delta$ to $c + \delta$ at every point the function is given to be differentiable in the interval $c - \delta$ to $c + \delta$.

So, f' is a function and I can ask whether f' is again differentiable at the point c or not. So, if the func; there is a point if at the point c f' is differentiable in an open neighborhood of the point c and the derivative function which is defined in that neighborhood now is again differentiable at the point c then we say that the function f is differentiable twice differentiable at the point c . So, it is some sense the derivative of the derivative function, but keep in mind to define that it is necessary that we should say that f is differentiable in an open neighborhood then only that will make sense.

So, twice differentiability means f is differentiable in a open neighborhood of c and the derivative function is again differentiable at the point c . So, we say f is twice differentiable at the point c and this is second derivative this is called the second derivative of f it c right when f' is differentiable it will have a derivative this f' itself will have a derivative at the point c and that normally we denoted as f'' , but that is short and as f'' at c . So, f'' at the top indicates the second derivative one also denotes the second derivative by $d^2 f$ by dx^2 at the point c . So, the first derivative as df by dx and now the second derivative is $d^2 f$ by dx^2 . So, there is a notion of the second derivative.

(Refer Slide Time: 24:21)

The concept of n -times differentiability and the n th derivative of f at c , denoted by $f^{(n)}(c)$, can be defined similarly:

$$f^{(n)}(c) := (f^{(n-1)})'(c), \quad n \geq 2.$$

If $f^{(n)}(c)$ exists for every $n \in \mathbb{N}$, we say f is infinitely differentiable at c .

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 9 / 28

So, one can go on defining provided the higher order derivatives the concept of n times differentiability and the n th derivative of f of c we can define provided. So, to say that f is n times differentiable we should at a point c we should say that the n minus 1th derivative exists in a neighborhood of the point c and is there differentiable at the point c .

So, that will denoted $f^{(n)}$ to be the n th derivative is denoted by this bracket at the top the n th derivative of c to be defined as look at the n minus one th derivative its derivative at the point c when our define will be called as the n times differentiability of the function. So, what will be the second derivative second derivative is the derivative of the derivative of the derivative function. So, we want to have a opportunity to use this, but is interesting to say concept that if every derivative of every order exists for a function then we say function is infinitely differentiable.

If you recall we had said that we will assume that the exponential function is differentiable e raise to power x is differentiable and is derivative is the function itself that is what we had looked at as a assumption and using that we had defined the derivative of the lock function.

So, exponential function derivative is itself. So, automatically that is one example of a function which is infinitely differentiable. So, let us conclude today's lecture by saying we have looked at the notion of differentiability of a function as the condition for analyzing local maxima minima. So, we had the continuity test for analyzing local

maxima minima and then we had the first derivative tests for analyzing local maxima minima, we will state in the next lecture what is called the second derivative tests for local maxima and minima of functions sufficient condition in terms of the second derivative.

Thank you.
