**Lecture – 39**

**Chain rules, higher order partial derivatives, local maxima and minima, critical points**

In the previous lecture, we had started looking at the notion of partial derivatives and how do you compute partial derivatives using chain rule for composite functions. So, let us look at some examples of computing partial derivatives using chain rule. So, the first example we look at is the example  $f(x, y)$  which is given by  $x^2 + y^2$  or  $x$  and  $y$  belonging to  $\mathbb{R}^2$ .

(Refer Slide Time: 00:41)

**Chain rules**

- Examples:
  - (i) Let  $f(x, y) = x^2 + y^2$ , for  $(x, y) \in \mathbb{R}^2$   
and  $x(t) = e^t$ ,  $y(t) = t$ ,  $t \in \mathbb{R}$ .  
Let  $w(t) := f(x(t), y(t))$ ,  $t \in \mathbb{R}$ .  
Then, by chain rule,  $w(t)$  is differentiable for all  $t \in \mathbb{R}$ , and we have  
 $w'(t) = 2(e^t)e^t + 2t = 2(e^{2t} + t)$ .
  - (ii) Let  $f(x, y) = x^2 + y^2$ , for  $(x, y) \in \mathbb{R}^2$ ,  
 $x(s, t) = s^2 - t^2$ , and  $y(s, t) = 2st$ ,  
for all  $(s, t) \in \mathbb{R}^2$ .

Calculus for ECM

35 / 75

So, let us find out why it is where this is the function of 2 variables and let us assume  $x$  itself is a function of a variable  $t$  given by  $x(t)$  is equal to  $e$  raised to the power  $t$ . So, keep in mind it is exponential function  $e$  raised to the power  $t$  where  $e$  is a number, we had looked at this function in the first lecture or second lecture and  $y(t)$  is equal to  $t$  for  $t$  belonging to  $\mathbb{R}$ . So,  $x$  is a function of  $t$  and  $f$  is a function of  $x$  and  $y$  is also a function of  $t$ . So, what will be  $f$  as a function of  $t$  we can actually put the values of  $f$  values of  $x$  in this formula. So, there will be  $x^2$  that is  $e$  raised to the power 2 plus  $t^2$ . So,  $f$

actually becomes a function of one variable and we can compute the derivative as if it is a function of one variable.

But we want to illustrate this as an example of chain rule. So, let us look at  $w$  as a function  $f$  of  $x$  and  $y$ . So, this gives us the value  $f$  is a function of  $x$  and  $y$  and  $x$  is a function of  $t$  and  $y$  is a function of  $t$ . So, by chain rule what will be the derivative of  $w$  with respect to  $t$  it is a partial derivative of  $f$  with respect to  $x$  into derivative of  $x$  that is  $\frac{dx}{dt}$  plus derivative of  $f$  with respect to the variable  $y$  into  $\frac{dy}{dt}$ . So, partial derivative of  $f$  with respect to  $x$  that we get from this equation. So, that is  $2xy$  is kept constant. So, that is  $2x$ . So, and  $2x$  is equal to  $e^t$ . So, you get the first term as  $2x \frac{dx}{dt}$ , but  $x$  is equal to  $e^t$ .

So, its derivative is  $\frac{dx}{dt}$  that  $e^t$  itself if you recall we had mentioned that for the exponential function the derivative is itself plus the contribution with respect to the second variable now. So, that will be partial derivative of  $f$  with respect to  $y$  into  $\frac{dy}{dt}$ . So, partial derivative of  $f$  with respect to  $y$  is  $2y$  and  $y$  is equal to  $t$ . So, that is  $2t$  into  $\frac{dy}{dt}$ . So,  $\frac{dy}{dt}$  is equal to one. So, that is only  $2t$ . So, using chain rule the derivative of  $w$  with respect to  $t$  is this expression which you can simplify into  $2e^t + 2t$ . So, that is let us look at the function same function  $f(x, y)$  is equal to  $x^2 + y^2$ .

But here  $x$  now is the function of 2 variables  $s$  and  $t$   $x$  of  $s$  and  $t$  is equal to  $s^2 - t^2$  and  $y$  of  $s$  and  $t$  is  $2st$ . So, it is the same function of 2 variables is same as before  $x^2 + y^2$ , but now  $x$  is a function of 2 variables  $s$  and  $t$ . So,  $s^2 - t^2$  and  $y$  also is a function of 2 variables  $s$  and  $t$ . So, if like you can put these values in  $x^2 + y^2$  and will get  $f$  as a function of  $s$  and  $t$  as a function composite function as a function of 2 variables, but the formula will look quite complicated. So, let us try to use chain rule to find the partial derivative of this. So,  $f$  is a function of 2 variables  $x$  and  $y$   $x$  itself is a function of 2 variables  $s$  and  $t$  and  $y$  also is a function of 2 variables  $s$  and  $t$ . So, partial derivative of the composite function.

(Refer Slide Time: 04:48)

Chain rules

For  $g(s, t) := f(x(s, t), y(s, t)), (s, t) \in \mathbb{R}^2$ ,  
 we have by chain rule,  

$$\frac{\partial g}{\partial s} = 2(s^2 - t^2)(2s) + 2(2st)(2t) = 4s(s^2 + t^2),$$
 and  

$$\frac{\partial g}{\partial t} = 2(s^2 - t^2)(-2t) + 2(2st)(2s) = 4t(s^2 + t^2).$$

Q.

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 36 / 75

So, what will be the composite function  $f$  of  $x$  st comma  $y$  s  $t$ ? So, we can compute the partial derivative of that function. So, the function is  $g(s, t)$  which is  $f$  of  $x$  t  $x$  st comma  $y$  s  $t$  s of  $t$  belonging to  $\mathbb{R}$ .

So,  $g$  is a function of 2 variables and  $s$  right  $g$  is a function of 2 variables  $s$  and  $t$  over this comes as a composite function  $f$  of  $x$  st  $y$  st. So,  $g$  as a function of 2 variables will have partial derivative with respect to  $s$  and with respect to  $t$ . So, how do you find that? So, partial derivative of  $g$  with respect to  $s$  to compute that will look at. So, little bit 2 terms coming partial derivative of  $f$  with respect to  $x$  and if you are differentiating with respect to  $s$  then the partial derivative of  $x$  with respect to  $s$ .

So, that will be the first term plus partial derivative of  $f$  with respect to  $y$  multiplied by partial derivative of  $y$  with respect to  $s$ . So, that will be the partial derivative of  $g$  with respect to  $s$ . So, let us compute that the partial derivative of  $g$  with respect to  $s$  will be partial derivative of  $f$  with respect to partial derivative of  $f$  with respect to  $x$  into the derivative of partial derivative of  $x$  with respect to  $s$ .

So, that it gives you this term plus the second derive second term that is a partial derivative of  $f$  with respect to  $y$  into the partial derivative of  $y$  with respect to  $s$ . So, that is a second term the similarly, we can find the partial derivative  $g$  with respect to  $t$  being first look at partial derivative of  $f$  with respect to  $t$  into the partial derivative of  $y$  with respect to  $t$  plus partial derivative of  $f$  with respect to  $y$  in terms of partial derivative of  $y$

with respect to  $t$  and all are put in terms of  $s$  and  $t$ . So, that your answer eventually is in terms of  $s$  and  $t$ . So, this is how you apply chain rule and compute the partial derivative of composite functions using what are called chain rules.

(Refer Slide Time: 07:06)

**Higher order partial derivatives**

Like functions of a single variable, we can analyze the existence of the partial derivatives of the functions  $f_x$  and  $f_y$  with respect to the variable  $x$  and  $y$ , namely

$$f_{xx} := \frac{\partial^2 f}{\partial x^2} := \frac{\partial}{\partial x} \left( \frac{\partial f}{\partial x} \right), \quad f_{yy} := \frac{\partial^2 f}{\partial y^2} := \frac{\partial}{\partial y} \left( \frac{\partial f}{\partial y} \right),$$

$$f_{xy} := \frac{\partial^2 f}{\partial y \partial x} := \frac{\partial}{\partial y} \left( \frac{\partial f}{\partial x} \right), \quad f_{yx} := \frac{\partial^2 f}{\partial x \partial y} := \frac{\partial}{\partial x} \left( \frac{\partial f}{\partial y} \right).$$

NPTEL (© Inder K. Rana, I. I. T. Bombay)      Calculus for ECM      37 / 75

Let us go to slightly next concept see in functions of one variable we said that if the first derivative the derivative of a function exists at every point in the domain then we can ask whether the function is differentiable again and if it is. So, we will get the; what is called the second derivative and similarly the third order derivative and so on. Similarly the partial derivatives are functions of one variable only.

So, if the partial derivative of a function of 2 variables say  $f_{xy}$  if the partial derivative of  $f$  with respect to  $x$  exist at all points then it is a function of 2 variables again and one can ask; what are its partial derivatives.

So, partial derivative  $f$  of  $x$  will have 2 partial derivative as again differentiating  $f$  of  $x$  with respect to  $x$ , and then differentiating this with respect to  $y$  or differentiating it with respect to  $x$  again itself.

So, each partial derivative will give you 2 more partial derivatives of higher order depending on the function. So, let us write these. So, that we are able to use them. So, the first one is  $f_{xx}$  which is also written as partial derivative with a power 2 here. So, dell

square  $f$  divided by  $\text{dell } x \text{ square}$ . So, this is how you read this. So, this is  $\text{dell square } f$   $\text{dell } x \text{ square}$  or is the second order partial derivative of  $f$  with respect to  $x$  and  $x$ .

So, what is this you take the function find its partial derivative with respect to  $x$  and then again find its partial derivative respect to  $x$ . So, this is partial derivative of  $x$  twice you can call it. So, partial derivative of  $f$  with respect to  $x$  that gives you function find its partial derivatives with respect to  $x$  the other possibility is you look at similarly with respect to  $y$ . So, look at the partial derivative of  $f$  with respect to  $y$ . So, that gives you one partial derivative function right this is a partial derivative  $f$  with respect to  $y$  and that may be differentiable with respect to  $y$  again.

So, we can find the partial derivative of this function this is the function of 2 variables keep in mind the partial derivative  $f$  with respect to  $x$  is a function of 2 variables as well as the partial derivative of  $y$   $f$  with respect to  $y$  is again a function of 2 variables if we assume it to be differentiable everywhere with respect to the variable.

So, then if the partial derivative of this function which is function of 2 variables with respect to  $y$  exists then this is called the second order partial derivative of  $f$  with respect to  $y$  or read as  $\text{dell square } f$  by  $\text{dell } y \text{ square}$  or  $f y y$  or simply saying it is a second order partial derivative of  $f$  with respect to  $y$  other possibilities are this function exists. For example, partial derivative of  $f$  with respect to  $x$  exists, but we instead of asking partial derivative of that with respect to  $x$  again we can ask what is the partial derivative of this with respect to  $y$  that may exists. So, that gives you another possibility that the partial derivative of  $f$  with respect to  $x$  its partial derivative with respect to the variable  $y$ .

So, that is written as  $\text{dell square } f \text{ dell } y \text{ dell } x$ . So, note that here  $x$  is. So, as if the bracket is removed and this  $\text{dell}$  is multiplied and called  $\text{dell square}$  and  $\text{dell } y \text{ dell } x$  right. So, there is only shorthand notation. So, you should read it as it is a second order 2 indicates the order  $f$  of the function  $f$ . So, partial derivative second order partial derivative of  $f$  what is the sec 2 orders first with respect to  $x$  and then with respect to  $y$ . So, you are going to read from right to left while as in if you can also write it as  $f$  of  $xy$  there you will read it is from left to right. So, you will be reading as  $x$  first and then with respect to  $y$ . So, keep in mind whether the; if this notation is used this is first find the partial derivative of  $f$  with respect to  $x$  and then with respect to  $y$  right. So, that is going

this. So, this lower suffix is going from left to right where as here in the denominator if you think it is the denominator it is going from right to left.

So, this is a second order partial derivative of the function  $f$  where the first you differentiate with respect to  $x$  and then differentiate with respect to the variable  $y$  similarly there will be a partial derivative what is denoted by  $y_x$ ; that means, you first differentiate with respect to  $y$  and then with respect to  $x$  also called partial derivative second order partial second order partial of  $f$  by  $\frac{\partial^2 f}{\partial x \partial y}$  or second order partial derivative of  $f$  with respect to  $y$  and then with respect to  $x$ . So, that is order here that is left to right and it is right and left you take the function partial derivative of  $f$  with respect to  $y$  first and then take its partial derivative with respect to  $x$ .

So, there are four partial derivatives available second order partial derivatives for a function of 2 variables all of them may not exist some of them may exist, but these are the possibilities of. So, these are called four second order partial derivatives of a function of 2 variables these  $f_{xy}$  and  $f_{yx}$  they are called the mixed second order partial derivatives because the variables  $x$  and  $y$  are mixed here. So, this is called  $f_{xx}$   $f_{yy}$ ; they are pure second order derivatives and these are called the mixed second order partial derivatives in general  $f_{xy}$  is not equal to  $f_{yx}$ .

So, caution should be taken that in general for a function of 2 variables the 2 mixed second order partial derivatives are not equal. So, there are sufficient conditions which ensure that when they will be equal will not go in to those conditions; however, will assume that for our purpose they are equal. So, those conditions are satisfied. So, these are called the higher order partial derivatives. So, they correspond to something like second order derivatives of a function of one variable now we are defining them because they find applications in economics commerce and management.

So, let us look at one example let us recall the Cobb Douglas function which was defined as  $q$  is equal to  $QKL^\alpha$  into  $L$  raised to the power  $\alpha$  once again this  $L$  is a typo it should be  $L$  raised to the power  $\beta$  where  $\alpha$  and  $\beta$  are positive constants  $K$  is the capital and  $L$  is the labor input for this function just.

(Refer Slide Time: 14:06)

**An application**

Recall

- Recall the production function in **Cobb-Douglas production model** is

$$q = Q(K, L) = AL^\alpha L^\beta, \text{ where } A, \alpha, \beta \text{ are positive constants}$$

and  $K$  is the capital input,  $L$  is the labour input.  
The marginal product of labour is

$$q_L := \frac{\partial q}{\partial L} = \alpha L^{\alpha-1} K^\beta = \frac{AL^\alpha L^\beta}{L} = \frac{\alpha q}{L}.$$

Similarly

$$q_K := \frac{\partial q}{\partial K} = \beta L^\alpha K^{\beta-1} = \frac{AL^\alpha L^\beta}{K} = \frac{\beta q}{K}.$$

Note that both the marginals are positive.

 NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 38 / 75

Now, we saw today that the marginal of the product of labor  $Q$   $L$  is partial derivative of  $Q$  with respect to  $L$  was obtained as this and the partial marginal of  $Q$  with respect to  $K$  was today, we got as  $\beta Q$  by  $L$  in the previous lecture. So, these are the marginals of the Cobb Douglas function which we obtained. So, let us look at the second order both the marginals are positive that we know. So, let us look at the second order for this.

(Refer Slide Time: 15:00)

**Application**

The second order partial derivatives give

$$q_{LL} = \frac{\partial^2 q}{\partial L^2} = \frac{\alpha[Lq_L - q]}{L^2} = \frac{\alpha(\alpha - 1)q}{L^2}$$
$$q_{KK} = \frac{\partial^2 q}{\partial K^2} = \frac{\beta[Kq_K - q]}{K^2} = \frac{\beta(\beta - 1)q}{K^2}$$

These tell us how marginals are changing.

**It is usually required of production function that as the values of the inputs increase, the marginal products decline.**

That requires that both  $q_{KK} < 0$  and  $q_{LL} < 0$ .

In our model these will hold when  $0 < \alpha, \beta < 1$ .

 NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 39 / 75

So,  $Q_{LL}$  will be second order partial derivative of  $Q$  with respect to  $L$ . So, that we can differentiate by looking at this one  $\alpha Q$  by  $L$ . So, it will be  $L$  square. So, by the

quotient rule. So, this will be  $L^2$  this will go up. So,  $\alpha$  times  $L$  into derivative of  $Q$  with respect to  $L$  minus the  $Q$  times  $\alpha$   $Q$  into derivative of  $L$  that is one. So, let us put this values. So, that is equal to. So,  $L$  into derivative of  $Q$  with respect to  $L$  minus  $Q$  into derivative of  $L$  that is  $Q$ . So, will be simplify that is  $\alpha$  into  $\alpha$  minus one into  $Q$  divided by  $L^2$ . So, that is a simple equation we get similarly  $Q$ ;  $Q$  the second order partial derivative of  $Q$  with respect to  $K$  is partial derivative of.

So, take the first order partial derivative that is we obtained in the previous. So, that is the partial derivative. So, this function is the first order partial derivative second order partial derivative using the quotient rule. So,  $K^2$  in the denominator numerator will be  $\beta$  times  $K$  into derivative of  $Q$  with respect to  $K$  minus  $Q$  times derivative of  $K$  that is equal to one. So, that gives us the second expression namely the second order partial derivative of  $Q$  with respect to  $K$  is  $\beta$  into  $\beta$  minus one divided by  $K^2$  into  $Q$ . So, these 2 expressions are the marginals they are the derivatives of marginals.

So, these will tell us how does the marginals change, right; what kind of functions the marginals are there. So, keep in mind that  $\alpha$  and  $\beta$  are positive and  $Q$  and  $L$  are positive. So, if  $\alpha$  is between 0 and 1 and  $\beta$  also is between 0 and 1. So, that will give us 1. So, normally in production in a production function we require that the values of inputs increase the marginal should decline if there is a increase in the values of the product function right then the; that means, if the inputs increase marginal should decline that is a normal principal guiding principal for economic models; that means, we want  $Q_L$  and  $Q_K$  to be a decreasing function for them to be decreasing functions we should have  $\alpha$  to be less than one and  $\beta$  should be less than 1.

So, that is the reason one normally if you want this property to be true that the functions the derivatives are derivative of the marginals these are the second order partial derivatives if they are negative then that condition will be true when  $\alpha$  and  $\beta$  both are less than one they are non-negative quantities. So, they should be between  $\alpha$  between 0 and one. So, in Cobb Douglas model normally one says  $\alpha$  and  $\beta$  are positive constants and they are between 0 and one. So, that is the basic assumption in Cobb Douglas model and the reason is as indicated here is basic principal of economics.

So, now, what we will be doing we will be will start looking at the notion of local maxima and local minima for functions of 2 variables if we recall for a functions of one

variable how we looked at the notion of local maxima and minima we first obtained a necessary condition namely that if at a point a function has local maxima or a local minima then the derivative and the derivative at that point exists, then the derivative should be equal to 0. So, that gave us necessary conditions gave us the possible points where the where the local maxima or the minima can occur and then we had various tests the continuity tests the first derivative test and the second derivative test to analyze whether those possible candidates for local maxima or minima are actually local maxima or minima for the function or not.

So, they were the sufficient conditions. So, we had necessary conditions for local maxima minima and sufficient conditions for local maxima minima the same process we are going to follow for functions of 2 variables. So, first we will define what is called as the local maxima and local minima for a function of 2 variables and then give necessary conditions for a function of 2 variables if it has a local maxima and or a local minima at a point then what are the conditions and then will look at the sufficient conditions to analyze those possible candidates where the function can have local maxima or local minima. So, let us look at the definitions.

(Refer Slide Time: 20:03)

### Local Maxima and minima

- Definitions:  
 Let  $f : D \rightarrow \mathbb{R}$ , where  $D \subset \mathbb{R}^2$  and  $(x_0, y_0) \in D$ .
  - (i) We say  $f$  has a point of local maximum at  $(x_0, y_0)$  if there is some  $\delta > 0$  such that
 

$(x, y) \in D \cap B_\delta(x_0, y_0)$   
 implies  $f(x, y) \leq f(x_0, y_0)$ .

 In this case the value  $f(x_0, y_0)$  is called a local maximum of  $f$ .
  - (ii) We say  $f$  has a point of local minimum at  $(x_0, y_0)$  if there is some  $\delta > 0$  such that
 

$(x, y) \in D \cap B_\delta(x_0, y_0)$   
 implies  $f(x, y) \geq f(x_0, y_0)$ .

 In this case the value  $f(x_0, y_0)$  is called a local minimum of  $f$ .

NPTEL (©Inder K. Rana, I. I. T. Bombay)

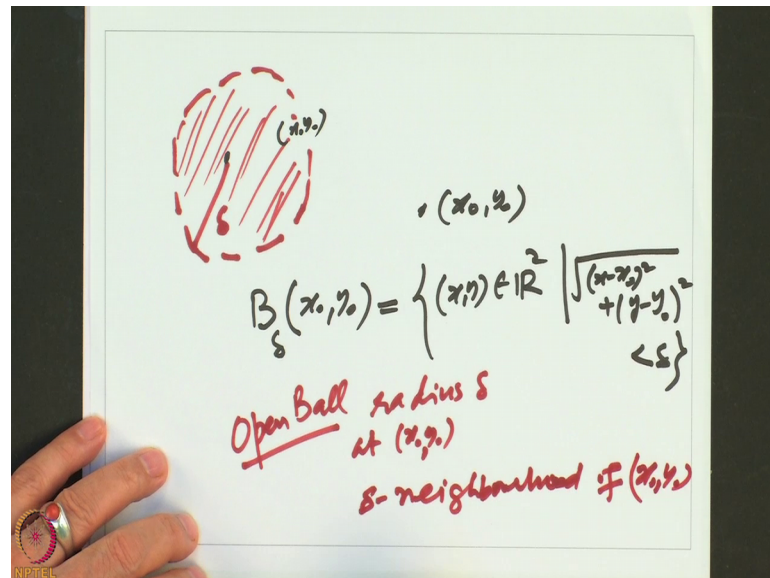

Calculus for ECM

40 / 75

So, the first definition says for a function of 2 variables with a domain  $D$ .  $D$  is a subset of  $\mathbb{R}^2$  a point  $x_0, y_0$  is called a point of local maximum. So, if there is a ball  $B_\delta(x_0, y_0)$  is nothing, but a ball centered at  $x_0, y_0$  of radius  $\delta$ ; that means, this is a set of all

points at a distance maximum of delta. So, let me just explain because we are not really explained this very well in the beginning, for a in the plane.

(Refer Slide Time: 20:46)

So, if it take a point  $x_0, y_0$ , then what is ball centered at  $x_0, y_0$  of radius delta. So, this is nothing, but this is a set of all points  $x$  and  $y$  belonging to  $\mathbb{R}^2$  such that the distance between  $x_0, y_0$  and  $xy$  is less than delta. So, what is the distance? So, the distance is  $\sqrt{(x-x_0)^2 + (y-y_0)^2}$  this is less than delta. So, this a set of all points and in the picture.

So, if this is the point  $x_0, y_0$  then these points are nothing, but the points which are at a distance of delta so; that means, at a distance of delta you are looking at, but strictly less than delta. So, you will be looking at all points in the disc, but minus the boundary the boundary is not going to be included. So, all points inside that is the ball that is a ball. So, we say it is a ball radius ball of radius delta at. So, at the point  $x_0, y_0$  because we are not including the boundary one normally actually qualifies open ball of radius delta this is also sometimes called the delta neighborhood b neighborhood of the point  $x_0, y_0$ .

So, recall in a function of one variable we defined the neighborhoods by the open intervals centered at that point here a  $b$  of  $x_0, y_0$  is an open ball in the plane centered at  $x_0$  and  $y_0$ . So, what we are saying is a point of local maxima at the point  $x_0, y_0$  if there is a neighborhood of that point in the domain of course, such that at all these points  $xy$  the value of the function is the largest.

So,  $f(x_0, y_0)$  is bigger than  $f(x, y)$  for all points in the  $\delta$  neighborhood of the point  $(x_0, y_0)$ . So, in this case we say it is a point of local maximum. So, locally, what does locally means in a open neighborhood of that point  $(x_0, y_0)$  and the domain the value is the largest. So, locally the value is the largest and similarly we say it is a point of local in this case we say that this value of the function the point is called the point of local maximum and the value of the function at that point is called the local maximum of the function.

One can define similarly the point of local minimum at  $(x_0, y_0)$  to be there the points.

(Refer Slide Time: 23:44)

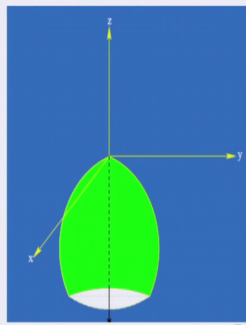

**Local Maxima and minima**

$(x, y) \in D \cap B_\delta(x_0, y_0)$   
implies  $f(x, y) \geq f(x_0, y_0)$ .

In this case the value  $f(x_0, y_0)$  is called a **local minimum** of  $f$ .

• **Examples:**

(i) Let  $D = \mathbb{R}^2$  and  
 $f(x, y) = -(x^2 + y^2)$   
for  $(x, y) \in \mathbb{R}^2$ .  
Then  $f$  has a local maximum at  
 $(0, 0)$  and the local maximum is  
 $f(0, 0) = 0$ .

NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 41 / 75

Such that there is a neighborhood  $\delta$  bigger than 0 with the property that the value at the point  $(x_0, y_0)$  is smallest for all points in that neighborhood open neighborhood open ball around the point  $(x_0, y_0)$  then you say it is a local minima and the value of the function at that point is called the local minimum that point is called the local minimum.

So, you can have look at some examples if I look at the function  $f(x, y)$  is equal to minus of  $x^2 + y^2$  then we had tried to visualize the graphs of this functions their surfaces this will look like a averted cup and the negative; that means, the surface is going to lie below the  $xy$  plane. So, the point  $(x_0, y_0)$  the point  $(0, 0)$  is going to be a point of local maximum the value will be 0.

So, the point  $(0, 0)$  is going to be point of local minimum and the value  $0$  is the local minimum for such a function.

(Refer Slide Time: 24:50)

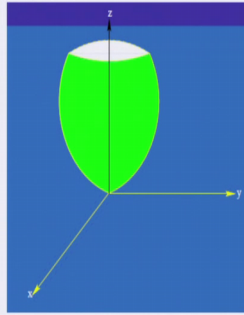

### Local Maxima and minima

(ii) If  $D = \mathbb{R}^2$  and

$$f(x, y) = x^2 + y^2$$

for  $(x, y) \in \mathbb{R}^2$ .

Then  $f$  has a local minimum at  $(0, 0)$  and the local minimum is  $f(0, 0) = 0$ .

- We have the following necessary condition for local maximum/minimum.

NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 42 / 75

If I just invert it. So, the function becomes  $f(x, y)$  is equal to  $x^2 + y^2$  for a  $(x, y)$  belonging to this then we get that the point  $(0, 0)$  is a point of local minimum and the value at  $(0, 0)$  is the local minimum for the function. So, this is a simple example of local maximum and minimum for the functions like functions of one variables we have the following necessary condition for local maximum and minimum.

(Refer Slide Time: 25:33)

### Necessary conditions for local extremum

- **Theorem:**  
If both  $f_x(x_0, y_0)$  and  $f_y(x_0, y_0)$  exist and  $f$  has a local maximum or a local minimum at  $(x_0, y_0)$ , then
 
$$f_x(x_0, y_0) = 0 = f_y(x_0, y_0).$$
- **Remark:**  
Let  $f(x, y) = \sqrt{x^2 + y^2}$ ,  $(x, y) \in \mathbb{R}^2$ .  
Then, both  $f_x$  and  $f_y$  do not exist at  $(0, 0)$ :
 
$$\frac{f(x, 0) - f(0, 0)}{x} = \frac{|x|}{x}.$$

NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 43 / 75

So, let us write this as a theorem that if  $f$  is a function which is defined in some open domain in  $\mathbb{R}^2$  a function of 2 variables if both the partial derivatives exist and  $f$  has a local maximum or a local minimum at the point  $x_0, y_0$  either of it, then the partial derivatives of  $f$  with respect to  $x$  and partial derivative of  $f$  with respect to  $y$  at that point must be 0.

So, what we are saying is if a point  $x_0, y_0$  is a point of local maximum or local minimum for the function and the partial derivative exists at that point then they must be equal to 0 which is perfectly similar to the function of one variable if local maximum or a local minimum for a function of one variable exists and if the function is differentiable then the derivative must be equal to 0.

So, that is the necessary condition that we get for a function of 2 variables to be point of local maximum or a local minimum, but keep in mind that if we look at the for examples the functions square root of  $x$  square plus  $y$  square this function does not have local maximum does not have partial derivatives at the point  $0, 0$  that you can easily check because this ratio  $f(x, y) - f(0, 0)$  divided by  $\sqrt{x^2 + y^2}$  they will be equal to  $\sqrt{x^2 + y^2}$  which is that limit does not exist at the point  $0, 0$ . So, for this function the partial derivatives do not exist, but the function has got a local minimum at the point  $0, 0$ .

So, keep in mind the function can have a local maximum or a local minimum without partial; of partial derivatives is the point of local minimum without.

(Refer Slide Time: 27:16)

### Critical points

However, the point  $(0, 0)$  is obviously a point of local minimum, with local minimum being  $f(0, 0) = 0$ .

Thus, the condition in theorem is only necessary, not sufficient.

• **Definitions:**

An interior point  $(x_0, y_0) \in D$  is called a **critical point** of  $f$  if

- (i) Either, both  $f_x$  and  $f_y$  exist with
 
$$f_x(x_0, y_0) = f_y(x_0, y_0) = 0.$$
- (ii) Or, one or both of  $f_x(x_0, y_0), f_y(x_0, y_0)$  do not exist.

NPTEL (© Inder K. Rana, I. I. T. Bombay)
Calculus for ECM
44 / 75

So, that is the condition in the theorem is only a necessary, but not sufficient condition. So, let us define what is called a critical point. So, like in one variable an interior point in the domain of the function will be called a critical point if either both  $f_x$  and  $f_y$  exist and are equal to 0 and second possibility is one or both of them do not exist like in one variable derivative may not exist or the points where there could be the boundary points the third one we are not listed here we should list that also. So, those also could be the points of. So, these are the interior points.

So, for interior points these are the only 2 possibilities partial derivatives exist and are equal to 0 or either or both of the partial derivatives do not exist. So, keep in mind this is for the interior points ok.

(Refer Slide Time: 28:20)

**Critical points**

- **Corollary :**  
For a function local maxima/minima can occur only at critical point or boundary points of  $D$ .

NPTEL (c) Inder K. Rana, I. I. T. Bombay      Calculus for ECM      45 / 75

So, as a corollary of this we will get that a function can have a local maxima minima can occur only at the critical points or possibly at the boundary points of the domain like in the function of one variable the critical points and the boundary points together give the possible candidates for the function to have a local maxima or minima. So, like in one variable we give sufficient conditions for the possible points to be local maxima or minimum same we will do it for functions of 2 variables in the next lecture, will continue our study of points of local maxima minima for functions of 2 variables in the next lectures.

Thank you.
