Lecture - 40
Saddle points, derivative tests, absolute maxima and minima

Welcome back to our discussion of points of local maxima and local minima for a function of 2 variables. In the previous lecture we had seen a necessary condition for a function of 2 variables to have a local maxima and minima at a point. So, we said if a function of 2 variables has partial derivatives at a point, and if the point is a local point of local maxima or a minima, then the partial both the partial derivatives with respect to the variables x and y should be equal to 0.

So, this gave us the possible candidates like in one variable where the function can have local maxima or minima. So, the points or the interior points in the domain, where the partial derivative exists and are equal to 0, or either of the partial derivatives does not exist, and the third possibility is the boundary points for the domain. So, we looked at some examples, and we saw there were some points which were neither local maxima or local minima, but the partial derivatives were 0 at that point.

So, let us that motivated us to look at what is called the saddle points for a function of 2 variables. So, we will define today what are the saddle point whatever what are called the saddle points for a function of 2 variables, and analyze them. So, a saddle point.

(Refer Slide Time: 01:54)

Saddle points

- **Definition:**
Let $f : D \subseteq \mathbb{R}^2 \rightarrow \mathbb{R}$ and $P \in D$ be a critical point.
We call a point P in D to be a **saddle point** of f if in every open ball B centered at P ,
there exist points Q and R in $B \cap D$ such that
$$f(Q) > f(P) > f(R).$$
- **Examples:**
(i) As shown above, for the function $f(x, y) = x^2 - y^2$, $(x, y) \in \mathbb{R}^2$, $(0, 0)$ is a critical point which is a saddle point.

 NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 50 / 74

Is a; suppose f is a function of 2 variables from \mathbb{R}^2 to \mathbb{R} . And P is a point in the domain, and let P be a critical point. So, the critical point is the interior point where the derivatives are equal to 0. So, we call P to be a saddle point if for every open ball centered at P , there is a point Q in the and there is a point R in the ball of course, in the domains is that, the value at the point Q is bigger than the value at the point P , and is bigger than the value at the point P .

That means every neighborhood of that point P , we has a point where the value is bigger than the value at P , and the point R where the value is smaller than the value at the point P . Such points are called saddle points. For example, let us look at the function $f(x, y)$ equal to $x^2 - y^2$, where x and y belong to \mathbb{R}^2 . And for this if we look at the partial derivatives, they turn out to be $2x$ and $2y$, and when they put them equal to 0, you will get $(0, 0)$ is a critical point. And our claim is that this is a saddle point. To show that, that is a obvious actually, because if I take a point close to the region and where y is 0. So, that is the point on the x axis, then the value will be positive. And if I take a point on the y axis then x will be 0, the value will be minus y^2 .

So, close to $(0, 0)$ we can have points where the value is positive and also, the points close to the origin where the value is negative. And the value at $(0, 0)$ the value is 0. So, $(0, 0)$ is a saddle point by the above definition.

(Refer Slide Time: 03:49)

Saddle points, examples

(ii) Let $f(x, y) = xy$, $(x, y) \in \mathbb{R}^2$.
Since for every $\delta > 0$,

$$f(\delta/2, \delta/2) = \frac{\delta^2}{4} > 0 = f(0, 0)$$

and

$$f(-\delta/2, \delta/2) = -\frac{\delta^2}{4} < 0 = f(0, 0),$$

Thus, $(0, 0)$ is a saddle point for $f(x, y) = xy$.
Since $f_x(x, y) = y$, $f_y(x, y) = x$,

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 51 / 74

Let us look at to the curve xy or function $f(x, y)$ is equal to xy . The domain of the function is the whole of \mathbb{R}^2 . And if I look at for every δ , look at the value of the function at the point $\delta/2, \delta/2$, then $f(x, y)$ will be equal to $\delta^2/4$, which is bigger than 0. At the same time, if I look at the value of the function at a point say $-\delta/2$ and $\delta/2$, then the value of the function will be $-\delta^2/4$ which is less than 0.

So, close by choosing δ sufficiently close to 0, we will see that we can find points close in the domain of the function, close to the origin where the values are positive and another point where the value is negative. So, this means $(0, 0)$ is also a point saddle point for this function of 2 variables $f(x, y) = xy$. note that $(0, 0)$ is a saddle point, and when if you look at the partial derivatives for this function, the partial derivative with respect to x is equal to y , and the partial derivative with respect to y is equal to x . And so, that means, $(0, 0)$ is in fact, a critical point. So, $(0, 0)$ is a critical point, but it is neither a maxima nor a minimum for the function. So, that means, $(0, 0)$ is a critical point and a saddle point.

(Refer Slide Time: 05:24)

Saddle points, examples

(iii) Let
 $f(x, y) = 2x^2y + yx^2, (x, y) \in \mathbb{R}^2$.
Along the line $y = x$, which passes through $(0, 0)$,
 $f(x, x) = 3x^3, x \in \mathbb{R}$,
and hence f takes both positive and negative values at points as close to
 $(0, 0)$ as we want.
Since $f(0, 0) = 0$, the point $(0, 0)$ is a saddle point for f .
Note that $(0, 0)$ is a critical point for f .

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 52 / 74

We can also look at some more examples like $2x^2y + yx^2$. For this if I look at the line passing through the origin, the line y equal to x passing through the origin, then the function looks like x is equal to y . So, that is x^3 and x^3 . So, that is $3x^3$. So, that means, close to $0, 0$, if it is on the positive side it will take the positive value. And on the negative x negative close to 0 it will take the negative value. So, $0, 0$ is a point of is the saddle point for this function. So, this is the way we can analyze saddle points by definition. Namely these are the points where, which are critical points for the function, but the function is neither taking the local maxima or nor is a local minima at that point.

In fact, every point for every neighborhood there is a point where the value is bigger and the neighborhood where the value is smaller.

(Refer Slide Time: 06:35)

Derivative test

- Definition:
Let $f : D \subseteq \mathbb{R}^2 \rightarrow \mathbb{R}$ and $(x_0, y_0) \in D$ be an interior point.
Let all the second order partial derivatives of f at (x_0, y_0) exist.

Then

$$\Delta f(x_0, y_0) := \begin{vmatrix} f_{xx}(x_0, y_0) & f_{xy}(x_0, y_0) \\ f_{yx}(x_0, y_0) & f_{yy}(x_0, y_0) \end{vmatrix}$$

is called the **discriminant** of f at (x_0, y_0) .

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 53 / 74

So, let us now look at what is called the derivative test for a function of 2 variables to be having a local maxima or local minima at a point. So, let us take a function of 2 variables $f(x, y)$, and let us (x_0, y_0) be an interior point. So, such that the both the second order partial derivatives of f at (x_0, y_0) exist. Then we define a quantity called the discriminant it is a 2 by 2 determinant. So, that is defined as the this is a notation used for discriminant, and defined as 2 by 2 determinant, Δf where the first row is f_{xx} the second order partial derivative at (x_0, y_0) , f_{xy} the partial derivative at the point (x_0, y_0) and here a cross is f_{yx} the partial derivative at (x_0, y_0) , and f_{yy} at (x_0, y_0) .

In case we have not seen this kind of object earlier, this is just you cross multiply the and you write. So, this is can also be written as $f_{xx} f_{yy} - f_{xy} f_{yx}$. So, that is the expanded form of this 2 by 2 determinant, a discriminant. And whether it is called the discriminant is a 2 by 2 determinant.

(Refer Slide Time: 08:13)

Derivative test

Theorem (Test for local max/min)

Let f be such that all the first and second order partial derivatives of f exist and are continuous at every point of $B_r(x_0, y_0)$ and $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Then, we have the following:

- (i) The function f has a **local maximum** at (x_0, y_0) if $\Delta f(x_0, y_0) > 0$ and $f_{xx}(x_0, y_0) < 0$ (or $f_{yy} < 0$).
- (ii) The function f has a **local minimum** at (x_0, y_0) if $\Delta f(x_0, y_0) > 0$ and $f_{xx}(x_0, y_0) > 0$ (or $f_{yy} > 0$).
- (iii) The function f has a **saddle point** at (x_0, y_0) if $\Delta f(x_0, y_0) < 0$.
- (iv) The Discriminant test is **inconclusive** at (x_0, y_0) when $f_x(x_0, y_0) = f_y(x_0, y_0) = \Delta f(x_0, y_0) = 0$.

NPTEL © Inder K. Rana, I. I. T. Bombay Calculus for ECM 54 / 74

So, the derivative test is in terms of this discriminant, which is something similar to the second order derivative test for a function of one variable. So, let us state this test for the local maxima and local minima for a function of 2 variables. So, let f be a function of 2 variables such that all its first and second order partial derivatives exist and are continuous at the point x_0, y_0 , in a neighborhood of the point x_0, y_0 .

Now, this condition basically is put to ensure that the mixed second order partial derivatives are equal. So, that is a sufficient condition. So, we want that the second order partial derivatives exist, and are continuous at every point in a neighborhood of the point x_0, y_0 . And the first order derivatives are 0. So, that means, this is a critical point. So, it is a critical point the second order partial derivatives exist, and our mixed partial derivatives are equal. So, we say that the test says that the function will have a local maxima at the point x_0, y_0 , if so, this is a sufficient condition, if the discriminant at that point is bigger than 0, and the partial derivative f_{xx} at that point is less than 0, or equivalently f_{yy} is less than 0, either of it is enough to ensure.

So, these 2 conditions that the discriminant is bigger than 0, and the partial derivative f_{xx} second order partial derivative with respect to x is less than 0. Or the partial derivative with respect to y is less than 0. So, these 2 conditions ensure that the function has a local maxima at the point x_0, y_0 . If the discriminant is still bigger than 0, but the partial derivative at the point f_{xx} a partial derivative second order partial derivative at

the point x_0, y_0 is bigger than 0 or equivalently the second order partial derivative with respect to y is bigger than 0. Then this will ensure that the function has a local minimum at the point x_0, y_0 .

So, this condition is for sufficient condition for local maxima, and this is a sufficient condition for local minimum. And in case if the discriminant is less than 0. So, this was bigger than 0 this is bigger than 0 this is in case the discriminant is less than 0, we can straight away conclude that the function will have a saddle point at the point x_0, y_0 . And in case discriminant is equal to 0, no conclusion can be drawn, from the conditions of f_{xx} a double derivatives or anything the function can have a local minimum function, can have a local minimum and may not have either of it if this condition is satisfied.

So, for a sufficient condition sufficiency condition for local maxima or local minima, first the discriminant should be positive. And if the second order derivatives f_{xx} is less than 0, then it is a local minimum. If it is bigger than 0, it is a a local minimum. So, these are this is what is called a second order derivative test for local minimum and local minimum. We will see some applications of this how this is applied. So, let us look at an example $f(x, y)$ is equal to $4xy - x^4 - y^4$.

(Refer Slide Time: 12:00)

Examples

(i) Let

$$f(x, y) = 4xy - x^4 - y^4 \text{ for } (x, y) \in \mathbb{R}.$$

Then,

$$f_x(x_0, y_0) = 4(y_0 - x_0^3)$$

and

$$f_y(x_0, y_0) = 4(x_0 - y_0^3).$$

Thus,

$$f_x(x_0, y_0) = f_y(x_0, y_0) = 0$$

gives us

$$(x_0, y_0) = (0, 0), (1, 1) \text{ or } (-1, -1).$$

NPTEL (© Inder K. Rana, I. I. T. Bombay)

Calculus for ECM

55 / 74

So, this function is the has partial derivatives of with respect to x and y at every point. So, let us find out the partial derivatives. And you find the partial derivatives with respect

to x. So, it will be 4x, right with respect to x. So, that will be 4y minus 4 with respect to x. So, it will be 4y minus 4x cube.

So, this will be the derivative partial derivative at the point x 0 y 0. Similarly, when you take the partial derivative with respect to y with respect to y, it will be 4x minus this will be 0, and this will be minus 4x 4y cube. So, that will be the partial derivative at the point x 0 y 0. So, to find the critical points we put them equal to 0, and once you put them equal to 0 and solve these equations from these 2 equations, it is easy to see that the solutions are 0 0 1 1 and minus 1 minus 1. We have not given the details here, but these 2 equal to 0, and we analyze because once it is equal to 0; that means, y 0 is equal to x cube. y 0 is equal to x cube and put the value here and solve and you will get the required values.

So, there are 3 critical points for this function 0 0 1 1 and minus 1 minus 1. So, let us look at the second order derivatives. The second order partial derivative with respect to x. So, we will look at this point. So, with respect to x we want to differentiate. So, this will give you 0, and this will give you 3. So, minus 3 into 4 that is minus 12x square and similarly the other partial derivative fyy at x 0 y 0.

(Refer Slide Time: 14:00)

Example

Since,

$$f_{xx}(x_0, y_0) = -12x_0^2, \quad f_{xy}(x_0, y_0) = 4, \quad \text{and} \quad f_{yy}(x_0, y_0) = -12y_0^2.$$

we have

$$\Delta f(x_0, y_0) = \begin{vmatrix} -12x_0^2 & 4 \\ 4 & -12y_0^2 \end{vmatrix}$$

$$= 16(9x_0^2y_0^2 - 1).$$

Hence,

$$\Delta f(0, 0) = -16 < 0, \text{ implying that } (0, 0) \text{ is a saddle point.}$$

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 56 / 74

We can calculate and the partial derivative of f x y is equal to 4. So, all the 3 partial derivatives are available, under that because we had put those conditions that mixed partial derivatives will be equal once the partial derivatives exist and are continuous.

So, this is going to be the case. So, the nearly this is required. So, in the discriminant the first term will be the partial derivative with respect to x x . So, that is $12x$ square the second term is the partial derivative x second order partial derivative that is equal to 4. So, the first term in the second row is the mixed partial derivative that is 4 again. And xy that that is minus $12y$ square. So, once you open that. So, and cross multiply; so, when you cross multiply 4 from where is common for so, 3 is common. So, that is 16 on the first-row or first column either one 4 is a common second also 4 is common so 16.

So, when you multiply this, this will give you $12 - 144x$ square y square minus 16. So, 16 out is common. So, mine x square y square minus 1. So, that is a discriminant, and we have to analyze this discriminant and those critical points which were 0 0 1 1 and minus 1 minus 1. So, at 0 0 the value is minus 16 that is less than 0. So, we can safely conclude that the point 0 0 is a saddle point. Because discriminant less than 0 gave you conditions sufficient a condition was that there should be a saddle point. So now, let us look at the discriminant for the value 1 1, when it is 1 1 it is going to be positive.

(Refer Slide Time: 15:53)

Example

Also,
 $\Delta f(1, 1) = \Delta f(-1, -1) = 128 > 0,$
 and
 $f_{xx}(1, 1) = f_{xx}(-1, -1) = -12 < 0.$
 Thus, f has a local maximum at $(1, 1)$ as well as at $(-1, -1)$.
 Further, along the line $x = y$, for $0 < x < 1$,

$$f(x, x) = 2x^2(2 - x^2) > 0,$$

and along the line $x = -y$, for all $0 < x < 1$,

$$f(x, -x) = -2x^2(2 - x^2) < 0.$$

Thus, the point $(0, 0)$ is a saddle point for f .

 NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 57 / 74

So, it is 128. So, the same value at the point minus 1 minus 1 because it is x naught square y naught square. So, it does not matter whether it is positive or negative. So, at 1 1 or minus 1 1 both the points the value of the discriminant is 128 which is bigger than 0.

So now let us analyze what is the value of f_{xx} at the point 1 1, and similarly at the point minus 1 minus 1, which you when you put the value in this at when you put is one that is

minus 12, when you put it one that is minus 1. So, you square so, either way it does not matter. So, whether plus 1 or minus 1 the value of the second order derivative is at 1 1 and minus 1 minus 1 are negative less than 0 so; that means what? That means, the points 1 1, and minus 1 minus 1 are points of local maxima. Because the discriminant at these points is bigger than 0 and the second order partial derivatives are less than 0.

So, these points are local maximum. So, both the points 1 1 and minus 1 minus 1 points of local maximum and for the function, we have already concluded 0 0 is a saddle point, but you can also analyze it by definition along the line y equal to x , f_{xx} is it always bigger than 0. And along the line x is equal to minus y , the function f_{yy} f_x minus y is less than 0. So, as close as you want near 0 0 you can have a positive value at a point and a negative value at 0 0 the value being 0. So, the function has a saddle point at the point 0 0.

(Refer Slide Time: 17:47)

Example

(ii) For the function $f(x, y) = -(x^4 + y^4)$,

$$f_x(0, 0) = f_y(0, 0) = \Delta f(0, 0) = 0,$$

and obviously f has a local maximum at $(0, 0)$.

On the other hand the function $f(x, y) = x^4 + y^4$ has a local minimum at $(0, 0)$

NPTEL (©Inder K. Rana, I. I. T. Bombay)

Calculus for ECM

58 / 74

So, one can also analyze more examples like the function $f(x, y)$ equal to minus $x^4 + y^4$. First order partial derivatives are equal to 0. And for this because it will give first order partial derivatives it will give you for x cube this will give you for y cube 4 2 equal to 0 0 0 is a critical point. And you calculate the second order partial derivatives, they are all 0. So, discriminant is also equal to 0. So, discriminant is 0. So, second derivative test is inconclusive for this case we cannot apply it; however, if we look at the function at 0 0

the value is 0, at every other point the value is negative. So, (0, 0) is going to be a point of local maximum for this function though the test fails.

Similarly, if I invert the function, change the sign here $x^2 + y^4$ for the all this will remain, the same the function will have a local maximum at the point (0, 0). Because in that case f at (0, 0) is 0, but f at every other point will have a positive value. So, the idea of this example is that when the discriminant is 0, and even if the point is a critical point. It may be a local maxima it may be a local minima as just now I exhibited. So, finally, let us look at another example of this function, for $x^3y - 4xy^3$.

(Refer Slide Time: 19:18)

Example

(iii) The function $f(x, y) = 4x^3y - 4xy^3$, satisfies the property that $f_x(0, 0) = f_y(0, 0) = \Delta f(0, 0) = 0$. Further, along the curve $(x_1(t), y_1(t)) := (t, -t/2)$, $t \in \mathbb{R}$,

$$f(x_1(t), y_1(t)) = -\frac{7t^4}{4} \text{ for every } t \in \mathbb{R}.$$

Thus, we can find points (x, y) close to $(0, 0)$ where $f(x, y) < f(0, 0) = 0$. Similarly, along the curve $(x_1(t), y_1(t)) = (t, t/2)$, $t \in \mathbb{R}$,

$$f(x_1(t), y_1(t)) = \frac{7t^4}{4} \text{ for every } t \in \mathbb{R}.$$

Thus, we can find points (x, y) close to $(0, 0)$ where $f(x, y) > f(0, 0) = 0$. Hence, f has a saddle point at $(0, 0)$.

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 59 / 74

And calculate the partial derivatives, and they come out to be 0 discriminant comes out to be equal to 0. But at this the point (0, 0), is a point of is a saddle point, which we can verify as follows, look at the values of the function along the curve t and t minus t by 2.

If I look, so, that means, x is equal to t and y is equal to minus t by 2, so, this is the curve going through (0, 0), and along this the value of the function is minus $7t^4$ by 4 which will be negative, for all points close to (0, 0). And similarly, if we change t to t by 2, the curve is $x = t$ and $y = t$ by 2. So, along this curve which is passing through (0, 0), the value of the function is $7t^4$ by 4. So, it will be positive. So, very close to (0, 0) the function takes the both the values positive and negative values. So, (0, 0) is a saddle point for this function, and the test fails.

So, these examples illustrate that the test may fail, but still the function may have a local maxima may have a local minima or a saddle point at the point where the test is failing.

(Refer Slide Time: 20:47)

Absolute maxima/minima

Definition

Let $f : D \subseteq \mathbb{R}^2 \rightarrow \mathbb{R}$.
 If there exists a point $\mathbf{a} \in D$ such that

$$f(x, y) \leq f(\mathbf{a}), \text{ for all } (x, y) \in D,$$

then the number $f(\mathbf{a})$ is called the **absolute maxima** of f in D .
 Similarly, if there exists a point $\mathbf{b} \in D$ such that

$$f(x, y) \geq f(\mathbf{b}), \text{ for all } (x, y) \in D,$$

then the number $f(\mathbf{b})$ is called the **absolute minima** of f in D .

Note :
 Recall that if D is closed and bounded, and f is continuous, then both absolute maxima and absolute minimum exist.

NPTEL © Inder K. Rana, I. I. T. Bombay Calculus for ECM 60 / 74

So, these examples illustrate those only conditions are sufficient, only when the discriminant is bigger than 0. Like one variable we can also look at the functions of 2 variables and define what is called an absolute maxima or a absolute minima of the function in the domain. So, f is a function defined in a domain \mathbb{R}^2 to \mathbb{R} , a point in the domain a vector a point \mathbf{a} in the domain D is called a point of absolute maxima, if f of \mathbf{a} is bigger than or equal to f of x, y for all x, y in the domain.

So, it is a global property. For all values in the domain f of \mathbf{a} is the value which is the largest. So, this is called absolute maxima. And the point is called the point of absolute maxima. And similarly, you can define absolute minima to be the point \mathbf{b} in the domain say that f of x, y the value of the function at every other point is bigger than or equal to the value of the function at that point.

So, that point is called the absolute point of absolute minima, and the value is called the absolute minima for the function. Going parallel 2 functions of one variable and again, going parallel to the function of one variable, recall that if a function is defined in a closed bounded interval for one variable the absolute maxima and the absolute we need my exists. And same property is true for functions of 2 variables.

(Refer Slide Time: 22:23)

Absolute maxima/minima

Theorem

Let $f : D \subseteq \mathbb{R}^2 \rightarrow \mathbb{R}$.

(i) Let f assume its absolute maximum at a point $\mathbf{a} \in D$.
Then, either \mathbf{a} is a boundary point of D , or is a critical point of f in D .

(ii) Let f assume its absolute minimum at a point $\mathbf{b} \in D$.
Then, either \mathbf{b} is a boundary point of D , or is a critical point of f in D .

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 61 / 74

So, what are the points where absolute maxima can occur? So, clearly a function is defined in a domain d in \mathbb{R}^2 . So, if a function has the absolute maxima at a point \mathbf{a} . So, then the point \mathbf{a} either is a boundary point or is a critical point for the function. So, that means, what either \mathbf{a} should be a critical point or \mathbf{a} is a boundary point it is a critical point meant, that either it is an interior point where the both partial order derivative for first order partial derivatives are equal to 0. Or the points where either of the partial derivatives does not at least one of the partial derivatives does not exist. Similarly, the for absolute minima.

So, that means, to find out the possible candidates where a function of 2 variables can have absolute maxima or absolute minima are the points, the boundary points or the critical points. So, to locate analyze a function and find it is a point of absolute maxima and absolute minima, what one does is; look at the function find out it is critical points, find out the boundary points, and analyze the values of function at these points perfectly similar to one variable situation.

(Refer Slide Time: 23:45)

Absolute maxima/minima

- **Note :**
To find the absolute maximum M and the absolute minimum m of a function $f : D \subseteq \mathbb{R}^2 \rightarrow \mathbb{R}$ on D , we compare the values of f at the critical points of f in D and the absolute minimum of the restriction of f to the boundary of D . The latter can often be found by reducing it to a one variable problem.

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 62 / 74

Some examples let us observe as I said we find out the critical points. We found out boundary points find out the values and compare ok.

(Refer Slide Time: 24:01)

Absolute maxima/minima Examples

(i) Suppose

$$D = \{(x, y) \in \mathbb{R}^2 \mid |x| \leq 2, |y| \leq 2\}$$

and $f : D \rightarrow \mathbb{R}$ is given by

$$f(x, y) = 4xy - 2x^2 - y^4.$$

Since D is a closed bounded set and f is a continuous function, it has both, absolute maximum and absolute minimum in D . For f both the partial derivatives exist everywhere and

$$f_x(x_0, y_0) = 4y_0 - 4x_0, \quad f_y(x_0, y_0) = 4x_0 - 4y_0^3.$$

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 63 / 74

So, let us analyze there one example. So, domain of the function is given there is x, y in \mathbb{R} $2 \leq x \leq 2$ mod x less than 2 mod y less than 2; that means, it is a square in the plane centered at $0, 0$ with length x going up to 2 and on the side minus 2.

So, the 4 corners are given by $2, 0$ minus $2, 0$, and similarly at the top it will be right. So, centered at the origin going up 2 units going down 2 units so, that is the square and here

is the origin. So, that is that so, the function given to us is $4xy - 2y^2 - x^2 - 4$. So, we want to find out the absolute maximum of this function in this domain. So, this domain has an interior and as well as a boundary the interior is when $|x|$ is strictly less than 2, and $|y|$ is strictly less than 2. So, that is inside of the square, and the boundary of the square is the normal boundary of the square, where $|x|$ is equal to 2 or $|y|$ is equal to 2.

So, let us analyze that. So, it is a continuous function. So, it will have absolute maximum and absolute minimum. And to find out that, let us look at the partial derivatives. So, these are the partial derivatives of the function of 2 variables.

Absolute maxima/minima Examples

$$f_x(x_0, y_0) = 4y_0 - 4x_0 = 0, f_y(x_0, y_0) = 4x_0 - 4y_0^2 = 0 \Rightarrow (x_0, y_0) = (0, 0), (1, 1) \text{ and } (-1, -1)$$

We need to compare values of F at these points and at the boundary points.
 For $(x_0, y_0) \in D$ is a boundary point if

$$x_0 = 2 \text{ or } x_0 = -2 \text{ or } y_0 = 2 \text{ or } y_0 = -2.$$

⊙

NPTEL (© Inder K. Rana, I.I.T. Bombay) Calculus for ECM 64 / 74

And when you put them equal to 0, that gives you $(0, 0)$, $(1, 1)$ and $(-1, -1)$. So, therefore, the 4th point is not visible here. So, that is so, we need to compare the values at these points. So, and the boundary points on a boundary point $|x|$ is equal to 2, or $|x|$ is equal to minus 2, $|y|$ equal to 2 and $|y|$ equal to minus 2.

So, when we put that values in the function.

(Refer Slide Time: 26:06)

Absolute maxima/minima examples

Due to symmetry of the domain, $f(-x, -y) = f(x, y)$.
Thus, we need only determine the absolute maximum and minimum of the functions

$$f(2, y) = 8y - 8 - y^4, \text{ for } -2 \leq y \leq 2$$

and

$$f(x, 2) = 8x - 2x^2 - 16, \text{ for } -2 \leq x \leq 2.$$

It is easy to check that the function

$$f(2, y) \text{ has absolute maximum at } y = \sqrt[3]{2}$$

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 65 / 74

So, and function is symmetric with respect to x and y . So, we need to determine the absolute maximum and absolute maximum of the function, we have to only find out f of $2 y$. So, there is a boundary point when x is equal to 2 that vertical line is given by this, and y goes between minus 2 to 2 . So, as a function of one variable and similarly for $x 2$ when y is equal to 2 so, that is the vertical line at the top, and x is varying between minus 2 to 2 . So far as for a function of one variable, we can analyze the conditions for this to be equal to 0 , and find out epsilon. So, one can check we leave it for you to check that as a function of one variable in y , it has a absolute maximum at the point y equal to cube root of 2 .

(Refer Slide Time: 26:58)

Absolute maxima/minima examples

It is easy to check that the function

$$f(2, y) \text{ has absolute maximum at } y = \sqrt[3]{2}$$

and

$$\text{absolute minimum at } y = -2.$$

Also,

$$f(x, 2) \text{ has absolute maximum at } x = 2$$

and absolute minimum at $x = -2$.

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 66 / 74

And similarly $f(2, y)$ has a absolute maximum at the point y is equal to cube root of 2 and the maximum at the point y equal to minus 2.

So, this is a function of one variable analysis will give you these values. So now, we can compare all the values of the function at all the points $f(0, 0)$ is 0 $f(1, 1)$ is 1, $f(2, \sqrt[3]{2})$ is equal to minus 40 $f(2, 2)$ it is equal to.

(Refer Slide Time: 27:17)

Absolute maxima/minima examples

Finally, we compare these values of f

$$f(0, 0) = 0, f(1, 1) = 1,$$
$$f(2, \sqrt[3]{2}) = 6\sqrt[3]{2} - 8, f(2, -2) = -40,$$
$$f(2, 2) = -8,$$

here we have ignored the points $(-1, -1)$ and $(-2, 2)$ due to symmetry.

Thus,

$$\text{the absolute maximum of } f \text{ is } 1.$$

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 67 / 74

So, at all the points boundary points and the critical points find the values and compare. So, we see that f of and also, we had we have ignored the points minus 1 and minus 2 2

because of symmetry. So, we can include that also. So, that means, epsilon maximum f is 1, and at the point 1 1 and minus 1 minus 1.

(Refer Slide Time: 27:51)

A slide titled "Absolute maxima/minima examples" with a light blue background. The text on the slide reads: "which is attained at the points $(1, 1)$ as well as at $(-1, -1)$, and the absolute minimum of f is -40 , which is attained at $(2, -2)$ as well as at $(-2, 2)$." The slide includes a small circular logo in the bottom left corner and a footer with the text "NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 68 / 74".

And similarly, it has a absolute maximum is minus 40 at the point 2 minus 2, minus 2, minus 2. So, this is how you analyze absolute maximum and absolute maximum of functions of 2 variables. will see some example of this in our economics model also.

Thank you.
