Lecture – 07

Limit theorems, sandwich theorem, monotone sequences, completeness of real numbers

So, welcome to today's lecture. We will continue our discussion on the concept of sequences. So, if you recall we are started looking at the notion of a sequence the convergence of a sequence and then we set the limit of a sequence is always unique we gave examples of sequences which are convergent and which are not convergent a non convergent sequence is also set to be divergent. We continue our study; we also looked at last time the notion of boundedness of a sequence namely all the terms of a sequence lie between 2 bounds. So, here is a theorem about convergence and boundedness it says that every sequence a_n which is convergent it is also bounded. So, convergent implies it is bounded.

(Refer Slide Time: 01:11)

So, boundedness is a necessary condition for a sequence to be convergent equivalently one can say not bounded implies not convergent. So, this is a theorem in calculus, we will not be proving this theorem. So, we will assume the proof of this theorem, those who are interested as I said can always refer to some book on calculus or look at the web

course on calculus developed under NPTEL. So, a sequence is convergent, then it is bounded. So, the use of this kind of a theorem is that if sequence is not bounded it cannot be convergent. So, this is how necessary conditions are used if a necessary condition is not satisfied then it is not prove that ah it should be convergent so; however, keep in mind that boundedness alone is not enough to say the sequence is convergent.

So, here is a example of a sequence which is bounded, but not convergent. So, this is minus one to the power n is a sequence which fluctuates between minus one to one and it is not convergent. So, let us look at some more theorems about convergence of sequences which help us to analyze the convergence of a sequence and these are theorems in calculus, but can be used.

(Refer Slide Time: 02:51)

Limit theorems : Algebra of limits

Theorem

Let $\{x_n\}_{n \geq 1}$ and $\{y_n\}_{n \geq 1}$ be sequences such that $\lim_{n \rightarrow \infty} x_n = x$ and $\lim_{n \rightarrow \infty} y_n = y$.

Then the following holds:

- (i) The sequence $\{x_n + y_n\}_{n \geq 1}$ is convergent and $\lim_{n \rightarrow \infty} (x_n \pm y_n) = x \pm y$.
- (ii) The sequence $\{x_n y_n\}_{n \geq 1}$ is convergent and $\lim_{n \rightarrow \infty} (x_n y_n) = xy$.
- (iii) If $y \neq 0$, then there exists some $n_1 \in \mathbb{N}$, such that x_n/y_n is defined for all $n \geq n_1$, and the sequence $\left\{ \frac{x_n}{y_n} \right\}_{n \geq n_1}$ is convergent with $\lim_{n \rightarrow \infty} \frac{x_n}{y_n} = \frac{x}{y}$.

NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 26 / 45

We will be using these theorems and either you can treat it as a rule for analyzing convergence of a sequence or you can if you are very keen as usual you can look at the proofs in the NPTEL web course. So, this says if a sequence x_n and y_n are sequences such that x_n convergence to x and a sequence y_n converges to y .

Then the following results hold you can give an x_n and y_n you can construct a new sequence called where each n th term of the new sequence is the sum of the n th term of x_n and the n th term of y_n . So, look at a new sequence whose n th term is x_n plus y_n where x_n is a sequence which is convergent and y_n is a sequence which is convergent then it says then the following holds the sequence x_n plus y_n is also convergent and its

result the limit of X_n plus Y_n is x plus y and similarly the you can have the difference of the 2 sequences. So, you can construct X_n minus y_n . So, limit of X_n minus Y_n is same as limit of X_n minus limit of y_n . So, it just we can intuitively keep it as the limit of the sum of sequence is equal to sum of the limits of the corresponding sequences and similarly for the difference of the 2 sequences.

The next results says about the product given a sequence X_n and given a sequence Y_n the n th terms can be multiplied together to get the sequence $X_n Y_n$. So, n th term of the new sequence is $X_n Y_n$. So, if X_n is convergent and if Y_n is convergent, then the sequence $X_n Y_n$ the product is also convergent and the limit is the product of the 2 limits. So, it says the limit of the product is equal to product of the limits if the either if the both the sequences is X_n and Y_n are convergent and the next is. So, we have looked at addition of sequences subtraction of sequences product next we want to look at th quotient of 2 sequences of course, X_n over Y_n will not be defined if Y_n is equal to 0 somewhere.

So, one has to put a extra condition that if the sequence Y_n is such that its limit y is not equal to 0, then the result says then for some stage onwards for some n one an actual number Y_n will not be 0; that means, X_n over Y_n is defined for all n bigger than or equal to n_1 from that stage onwards. So, we have a sequence X_n over Y_n which starts with n_1 onwards. So, this sequence is convergent and its limit of X_n over Y_n is equal to x over y .

So, limit of the convergent sequence is this equal to limit of the quotient of convergent sequences is the quotient of the limit provided the quotient limit is not equal to 0. So, these are 4 basic results about the algebra of limits because we are adding sequences, we are multiplying sequences subtracting and then dividing sequences. So, basically says that the limiting operations preserves the algebra if appropriately defined. So, quotient for the quotient we need y not equal to 0.

So, these results can be used to analyze convergence of sequences. So, there is another theorem which again will not be proving will be using it says the following suppose you have got 3 sequences a_n , b_n and c_n .

(Refer Slide Time: 06:58)

Sandwich theorem

Theorem
 Let $\{a_n\}_{n \geq 1}$, $\{b_n\}_{n \geq 1}$ and $\{c_n\}_{n \geq 1}$ be sequences such that
 $a_n \leq b_n \leq c_n$ for all $n \in \mathbb{N}$ and $\lim_{n \rightarrow \infty} a_n = l = \lim_{n \rightarrow \infty} c_n$.
 Then
 $\lim_{n \rightarrow \infty} b_n = l$.

Example: Let $b_n = \frac{\sin^5 n}{n^2}$, $n \geq 1$. Is it bounded? Convergent?

$$0 \leq \frac{|\sin^5 n|}{n^2} \leq \frac{1}{n^2} \leq \frac{1}{n} \leq 1.$$

By Sandwich theorem,

$$\lim_{n \rightarrow \infty} \frac{|\sin^5 n|}{n^2} = 0.$$

 NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for EGM 27 / 45

So, there are 3 sequences with the properties that the sequence b_n is in between a_n and c_n for every n ; that means, all the terms of the sequence c_n , it is not really require that all the terms from some stage onwards if it is true that is also good enough one can forget a few first few terms of the sequence. So, we want a_n less than or equal to b_n less than or equal to c_n . So, that is one condition and is a_n and c_n both converge to the same limit say l , then the result says then the limit b_n also exist the b_n is also convergent and is equal to l .

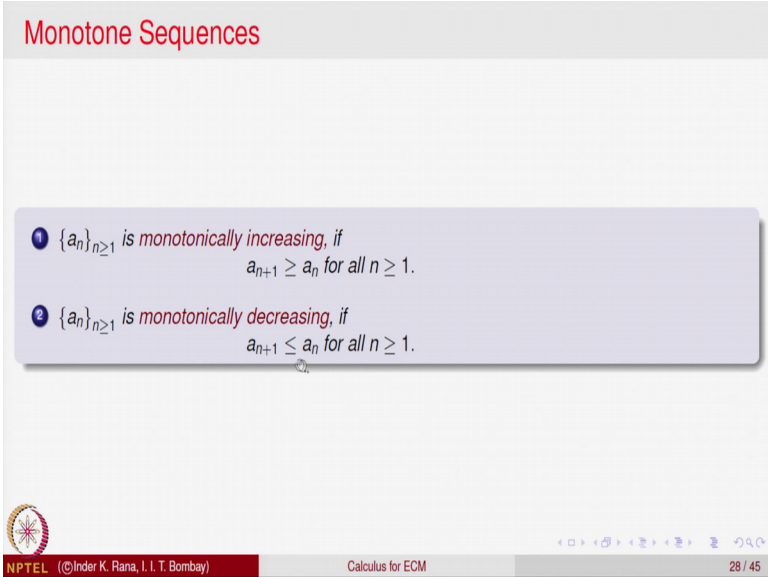

So, basically what we are saying is that if the terms of a sequence are sandwiched between 2 convergent sequences and there are convergence of a_n and c_n in which it between which it is sandwiched is same both a_n and b_n converge to l then b_n also will converge to l this is known as the sandwich theorem which is also quite useful again we will not be proving this result. So, let us look at the example for example, let us look at the sequence b_n which is \sin ; \sin is a trigonometric function if you know it very good if you do not know it, I think you have look at it in some school book how the trigonometric functions are defined. So, we will not go into the definitions of trigonometric functions only for the sake of examples we will see basically \sin of a angle θ is defined.

And this for every θ $\sin \theta$ is between minus one and one. So, this is basic property that will be using. So, b_n is the sequence which is defined as \sin to the power 5 of n and

divided by n^2 now since the sequence b_n is bounded it is convergent. So, this is a question to analyze its boundedness let us look at the absolute value of b_n . So, that will be equal to the absolute value of $\sin 5$ to the power n by n^2 since \sin is bounded by minus one to one mod \sin is bounded between by 1. So, we get that $\sin 5^n$ divided by n^2 this absolute value of b_n is always on negative absolute value is non negative is less than or equal to $1/n^2$ which is less than equal to one over n . So, which is less than 1. So, this is a bounded sequence and since it is bounded between 0 and $1/n$ and $1/n$ convergence to 0. So, this b_n mod b_n is in between 0 and $1/n$.

So, why sandwich theorem we get that this also convergence to 0 now \sin this. So, this is absolute value of b_n which converges to 0 and it is again a easy result which will assume that if mod b_n convergence to 0 then b_n also convergence to 0. So, that will imply the. So, we have looked at some tools which help us to analyze convergence of sequences namely algebra of limits and the notion of sandwich theorem here are some more concepts about sequences which are very useful and important.

(Refer Slide Time: 10:41)

Monotone Sequences

- 1. $\{a_n\}_{n \geq 1}$ is *monotonically increasing*, if $a_{n+1} \geq a_n$ for all $n \geq 1$.
- 2. $\{a_n\}_{n \geq 1}$ is *monotonically decreasing*, if $a_{n+1} \leq a_n$ for all $n \geq 1$.

NPTEL (©Inder K. Rana, I. I. T. Bombay) Calculus for ECM 28 / 45

So, we say a sequence a_n is monotonically increasing if a_{n+1} is bigger than a_n for every n ; that means, every term a_{n+1} is bigger than the previous term that is a_n .

So, as you as n increases you values of your sequence keep on increasing keep in mind we are saying bigger than or equal to we are not saying strictly bigger, right. So, if it is

equal it will be for saying the sequences monotonically increasing. So, we want for every n the next term that is $n + 1$ is bigger than or equal to the previous term that is a_n . So, then it is we say it is a monotonically increasing sequence. Similarly, we will say a sequence is monotonically decreasing if a_{n+1} is less than or equal to a_n ; that means, as n increases the values of a_n decrease right a_{n+1} is less than or equal to a_n again, we are saying less than or equal to we are not saying strictly less than. So, the next term is at the most the previous one; it could be smaller. So, that is called a monotonically decreasing.

So, monotonically increasing and monotonically decreasing if you want to say strictly bigger if you want to have that condition then we will say it is strictly monotonically increasing and similarly we will say a sequence is strictly monotonically decreasing if a_{n+1} is strictly less than a_n or all n bigger than a_n .

(Refer Slide Time: 10:23)

Examples Monotone Sequences

- Is the sequence $\{2n\}_{n \geq 1}$ monotonically increasing?
Yes.
 Is it bounded above?
No.
- Is the sequence $\{\frac{1}{n}\}_{n \geq 1}$ monotonically increasing / decreasing?
Yes, it is decreasing, and is bounded below, say by 0.
- Sequence $\{(-1)^n\}_{n \geq 1}$ is
neither monotonically increasing nor decreasing. Is it bounded? Yes.
- A sequence $\{a_n\}_{n \geq 1}$ monotonically decreasing if and only if $\{-a_n\}_{n \geq 1}$ is monotonically increasing.

NPTEL (©) Inder K. Rana, I. I. T. Bombay
Calculus for ECM
29 / 45

So, for example, if we look at the sequence $2n$, it is strictly monotonically increasing because the first term is 2 the second term is 4 next term is 6 and so on. So, as n increases the values of a_n strictly increase, yes, it is monotonically increasing is it bounded above we know it is not bounded above because for n sufficiently large you can make $2n$ as large as you want. So, it keeps on increasing it is a sequence which is monotonically increasing and it is not bounded above of course, it is bounded below their all the terms are non negative.

So, it is not bounded above let us look at the sequence $1/n$, we already analyze the sequence first term is one second term is $1/2$ third is $1/3$ fourth is $1/4$ and so on. So, it is a monotonically decreasing sequence which is bounded above by one and bounded below by 0. So, this is the monotonically increasing sequence monotonically decreasing sequence and it is bounded above as well as below; let us look at the sequence $(-1)^n$. So, what are the terms of the sequence we have seen it is the fluctuating sequence it is neither increasing nor decreasing because the first term is minus 1 second term is one third term is minus one fourth term is plus 1 and so on.

So, it is a bounded sequence, but it is not monotonically increasing nor it is monotonically decreasing. So, it is a sequence which is bounded, but not increasing not decreasing an obvious simple fact is that if a sequence a_n is monotonically increasing, then negatives of those terms of the sequence will be monotonically decreasing and conversely. So, a sequence is monotonically decreasing if and only if $-a_n$ is monotonically increasing and vice versa you can also say that a sequence is monotonically increasing if and only if $-a_n$ is monotonically decreasing. So, this is one way of going from increasing to decreasing or decreasing to increasing.

So, here is an important property of real numbers which we said we will state at an appropriate stage.

(Refer Slide Time: 15:06)

Completeness property of real numbers

- Every monotonically increasing sequence which is bounded above is convergent.
- Equivalently If $\{a_n\}_{n \geq 1}$ is monotonically decreasing and is bounded below, it is convergent.
- Let A_n denote the area of the 2^n sided regular polygon inscribed in the unit circle. Then $\{A_n\}_{n \geq 1}$ monotonically increasing and is bounded above! Hence it is convergent. The limit of this sequence is denoted by the Greek letter π , called Pi.

• How to find $\sqrt{2}$?

$$\sqrt{2} = \lim_{n \rightarrow \infty} x_k$$

where $x_0 = 1$ and

$$x_{k+1} = \frac{1}{2} \left(x_k + \frac{2}{x_k} \right).$$

NPTL (© Inder K. Rana, I. I. T. Bombay) Calculus for EGM 30 / 45

So, we can now state the property of real numbers that every monotonically increasing sequence of real numbers one would specify that every monotonically increasing sequence of real numbers which is bounded above will always be convergent. So, this is a property of real numbers, you can take it and assume for real numbers and when one constructs real numbers from the rational numbers this property automatically comes in. So, this is what is called the completeness property of a real number it is a very important property and an equivalent way of saying the same property would be in terms of decreasing sequences every monotonically decreasing sequence of real numbers.

Which is bounded below is also convergent this property is not always true for sequences of rational numbers one can have a sequence of rational numbers which is monotonically increasing and bounded above, but it will not converge to a rational number. So, in the domain of rational numbers this property is not true this property is true for that was actually one of the reasons why one wanted to enlarge the collection of rational numbers to a bigger class of real numbers.

So, real numbers have that property that every monotonically increasing sequence of real numbers which is bounded above is convergent and every equivalently every monotonically decreasing sequence of real number which is bounded below is also convergent some of the applications of this property are the following will not be going to the proofs of those properties.

Let us look at let a_n denote the area of $2n$ sided regular polygon inscribed in unit circle. So, you are given let us look at this property you are given a unit circle.

(Refer Slide Time: 17:12)

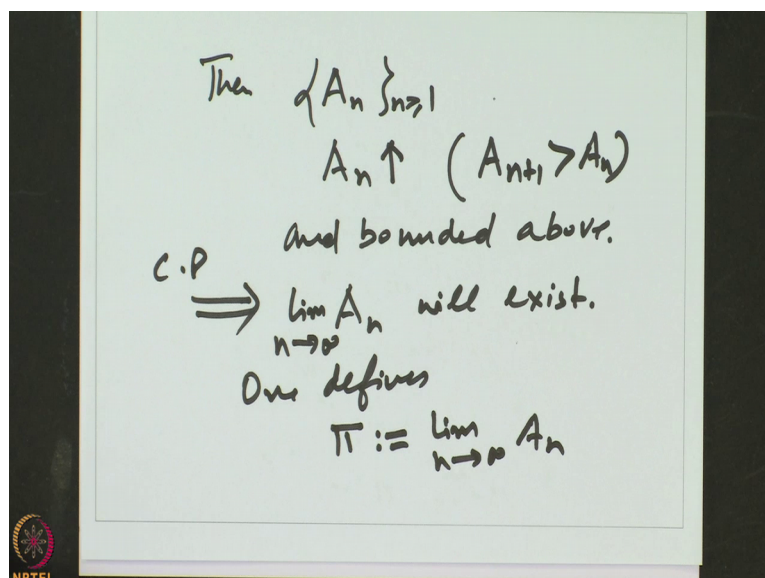

Unit circle means what you are given a circle of radius one. So, this is a unit circle its radius is one this is one unit one would like to find out what is a area of the unit circle normally in your schools school books one assumes the fact that area of the unit circle is a number called pi here is a precise definition of that using the completeness property let us try to estimate the area of the unit circle to estimate this what we will do is let us inscribe inside inscribe inside this unit circle a square. So, this is a square say A, B, C and D.

So, it is a regular 4 sided figure inscribed inside the circle. So, if I look at the area of the circle of the square that we can find out because we know this side is one this side is 1. So, I can find out the area of this 4 triangles using the formula half base into height. So, area of the 4 sided ah polygon regular polygon inscribed in the circle is known. Now let us increase this value let us take the midpoints of this arcs and join and join these points. So, we are joined. So, now, look at let us call this points as P, Q, R and S. So, if I look at the polygon A P B Q C R D S that is a 8 sided polygon inscribed inside the square inside the circle of radius 1. So, earlier the area of the square the square filled up a part of the circle now we added these triangles these 4 triangles.

So, the octagon now fills more part of the circle then compare to the circle, then compare to the square and the area of this octagon is quite easy to find because this side is one.

So, half base into height again you can find out this area. So, what we are saying is if we write a_n equal to the area of the $2n$ sided regular polygon inscribed in c ; c is the circle.

(Refer Slide Time: 20:37)

Then this a_n is a sequence of numbers and quite clear that a_n is monotonically increasing so; that means, a_{n+1} is strictly bigger than a_n . So, this is the monotonically increasing sequence of areas and from the figure it is quite clear that if I keep on increasing the number of sides I will slowly and slowly fill up the unit circle ok.

And it is also obvious that if I look at the square outside then the areas of all this $2n$ sided regular polygons inscribed they are increasing, but they never go outside the area of the circumscribed square so; that means, this is monotonically increasing and bounded above. So, implies by the completeness property of real number that limit n going to infinity a_n will exist and this limit one defines π to be the number which is this limit. So, this is the rigorous definition of area of the unit circle namely π as an application of the completeness property of real numbers.

So, this is one of the applications of real numbers. So, if you take the regular $2n$ sided regular polygon inscribed in the unit circle then this is a monotonically increasing sequence which is bounded above and hence will converge. So, the limit is called by denoted by the Greek letter π that is the area of the unit circle this is one of the rigorous ways of defining area of the unit circle another application of the completeness property how does one find square root of 2 of course, you will say what is the point we can

always divide and then do it right, but can we have an algorithm for finding this, yes there is possible. This was given by Isaac Newton which said that let us define let us start with the number x_0 equal to 1 and iteratively define x_{k+1} to be equal to $1/2$ of $x_k + 2/x_k$.

So, once x_k is defined x_{k+1} is defined and one shows this sequence of real numbers is convergent using the completeness property and the limit is nothing, but limit exists and that is what is called square root two. So, here is another way of appreciating the concept of limit of a sequence that square root 2 if you have seen earlier we also mentioned that square root 2 is an irrational number. So, its value cannot be found exactly like π the value of square root 2 cannot be found exactly, but since the sequence x_{k+1} or x_k is coming closer and closer to this. So, for large x_k ; x_k can be taken as a rational approximation for square root 2 and these are the approximations more often they are not used in putting algorithms in the calculators and so on.

So, this is a very practical application of convergence of a sequence of real numbers. So, we have looked at sequences of real numbers we have looked at the limit of sequence of real numbers and seen various ways of analyzing convergence and the completeness property of real numbers here are some important sequences which are useful for example.

(Refer Slide Time: 25:04)

An important sequence

- Let $x \in \mathbb{R}$ with $|x| < 1$.
 Is the sequence $\{x^n\}_{n \geq 1}$ convergent? If yes, what is the limit?
 Note that for $1 > x > 0$, the sequence $\{x^n\}_{n \geq 1}$ is monotonically decreasing and is bounded below by 0. Hence it is convergent by the completeness property.
Guess: It converges to 0.
+ Proof
- For $x > 0$, consider the sequence $\{x^{1/n}\}_{n \geq 1}$.
Guess: $\lim_{n \rightarrow \infty} x^{1/n} = 1$.
+ Proof

NPTEL (© Inder K. Rana, I. I. T. Bombay)
 Calculus for EGM
31 / 45

If $|x| < 1$, x^n is a real number with $|x| < 1$ then $|x|^n$ will in some sense come closer and closer to 0 and one can prove that the limit exists it is a monotonically decreasing sequence bounded below and it converges and actually it converges to 0, one can prove it rigorously using the tools we have described what will not go and do it.

But we will use this because it is a useful limit for a number between said positive number between 0 and 1; if you take its powers they keep on decreasing and decrease to 0 for $|x| > 1$; here is another one for x non negative if you take the n th root of x that is $x^{1/n}$ like square root cube root there is n through possible for real numbers if you take the sequence then intuitively one denominator n is going to infinity. So, $1/n$ intuitively is going to 0. So, intuitively this limit should go to x^0 that is one that is not a proof that is only a way of guessing that this limit exist and this equal to 1 can be proved rigorously there are more examples of this.

(Refer Slide Time: 26:23)

Example

(iii) Consider the sequence $\{a_n\}_{n \geq 1}$, where

$$\forall n, a_n = a + ar + \dots + ar^{n-1}, \text{ and } a, r \text{ are fixed.}$$

It is easy to check that $a_n = \frac{a(1-r^n)}{1-r}$.

Thus,

$$\lim_{n \rightarrow \infty} a_n = \frac{a}{1-r}, \text{ if } |r| < 1.$$

The sequence is divergent for $|r| \geq 1$.

For $|r| < 1$, we write

$$(a + ar + \dots + ar^{n-1}) = \frac{a}{1-r}$$

and $\frac{a}{1-r}$ is called the **sum** of the **geometric series**: a, ar, ar^2, \dots

 NPTEL (© Inder K. Rana, I. I. T. Bombay) Calculus for ECM 32 / 45

For example you have seen geometric progression in your school a, ar, ar^2, \dots is equal to $a + ar + ar^2 + \dots$. So, the geometric progression with first term a and common ratio r then we know that the n th term can be expressed as $a(1 + r + r^2 + \dots + r^{n-1})$ divided by $1 - r$ and that is a simple fact that can be reduced now if $|r| < 1$ say r is between 0 and 1 and I take the limit this is going to go to 0. So, this says that limit of a_n is a divided by $1 - r$ right for $|r| < 1$ if $|r| \geq 1$ this is going to

keep on increasing. So, it is an unbounded sequence the fact that limit of a^n is a over $1 - r$ as if r is between 0 and 1 that is written as that we write call this as a geometric series $a + ar + ar^2 + \dots + ar^{n-1} + \dots$ so on.

This is called a geometric series as an infinite sum of some kind of some they are on left hand side and says is an infinite sum actually exist and is equal to a over $1 - r$ if r is between 0 and 1 . So, this is a sum of a geometric series which is once again an application of the fact that r to the power n when r is between 0 and 1 converges to 0 . So, that is another way of looking at.

So, we conclude our lecture today for sequences by saying that sequences provide a intuitive tool for analyzing something happening at different at regular intervals at tie at different tie points and helps us to analyze them eventually when n becomes large what happens to that we will see the applications obvious in the lectures to come.

Thank you.
