**Topology of Real Numbers: Connected Sets; Limits and Continuity Part 1.**

(Refer Slide Time: 00:21)

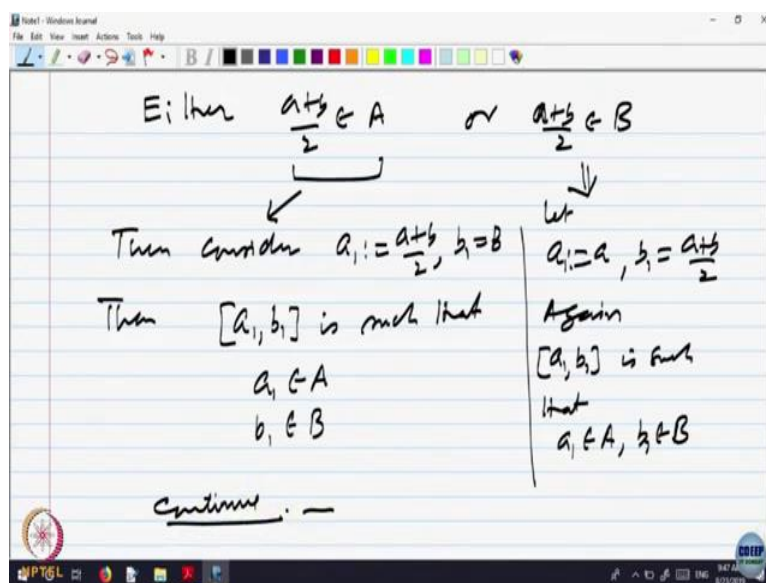

So, last time we were trying to prove a theorem that a subset  $S$  of real line is connected if and only if it is an interval. So, we have already proved one way. So, namely if  $S$  is connected, then  $S$  is an interval.

So let us proof the converse part of it. So, conversely so let  $S$  be an interval and suppose  $S$  is not connected. So, that implies if  $S$  is not connected it must be having a separation. So, let us say  $S$  is equal to  $A$  union  $B$ , a separation of  $S$ . That means  $S$  is written as union of two sets where  $A$  and  $B$  both are separated. So, let us choose an element  $a$  belonging to  $A$  and an element  $b$  belonging to  $B$ . So, here is  $a$  and here is  $b$ . Because it is a separation, so  $S$  is equal to  $A$  union  $B$  when  $A$  and  $B$  are of course non-empty sets and  $A$  is separated from  $B$  and  $B$  is separated from  $A$ .

So, let us choose any element  $a$  in  $a$  and  $b$  in  $b$  and look at the element which is the midpoint of the two. So, then the midpoint should belong to, it is between  $a$  and  $b$ . So, let us write that is a point we know that this is in between  $a$  less than  $b$  implies, we have got  $S$  as a interval. So, anything in between must be a part of an element in the interval. So, imply is  $a$  plus  $b$  by  $2$  belong to  $S$ . Now, if it belongs to  $S$ ,  $S$  is  $A$  union  $B$ . So, it will either belong to  $A$  or to  $B$ . So, two possibilities.

(Refer Slide Time: 03:24)

So, either  $a + b$  by 2 belongs to  $A$  or  $a + b$  by 2 belongs to  $B$ . So, if this is the case, is this is the case. So, then consider  $a_1$  let us call this point as  $a_1 = a + b$  by 2 and  $b_1$  equal to  $b$ . So, if it belongs to  $A$  then I call it as  $a_1$  and the right point  $b$  that point  $b$  we call it as  $b_1$ . So, what does it give me then  $a_1, b_1$  is such that  $a_1$  belongs to  $A$  and  $b_1$  belongs to  $B$ . So, what I have done is taken two points  $a$  and  $b$  look at the midpoint, midpoint must be a part of the interval.

So, it must belong to either  $A$  or  $B$  if it belongs to  $A$  call it  $a_1$  and call  $b$  as  $b_1$ . So, what is second possibility if this is the case then  $a_1$  then this belongs to  $B$ . So, define  $a_1$  equal to  $A$ , so let and  $b_1$  equal to  $a + b$  by 2 again  $a_1, b_1$  is such that, so what is happening is such that again  $a_1$  belongs to  $A$  and  $b_1$  belongs to  $B$ .

So, either case I have gotten is interval  $a_1, b_1$  such that the left hand point belongs to  $A$  and the right hand belongs to  $B$ , whichever the case may be and other property that  $a_1, b_1$  is half of  $a, b$ . The interval  $a, b$ , we are taking, one of them is an midpoint. So, either it is  $a$  to  $a + b$  by 2 or  $a + b$  by 2 divide to  $b_1$ . So, it is only half of it. So, length of this interval  $a_1, b_1$  is half of the length of the original one.

(Refer Slide Time: 06:06)

Continuum. — To find

$$[a_n, b_n] \text{ s.t. } a_n \in A, b_n \in B$$
$$\text{length } [a_n, b_n] = \frac{1}{2} \text{ length } [a_1, b_1]$$
$$= \frac{1}{2^n} \text{ length } [a, b]$$

This will give us a nested  
sequence  $\{[a_n, b_n]\}_{n \geq 1}$  of closed  
bounded intervals such that  
 $a_n \in A, b_n \in B \forall n \geq 1$   
and  $(b_n - a_n) \rightarrow 0$  as  $n \rightarrow \infty$

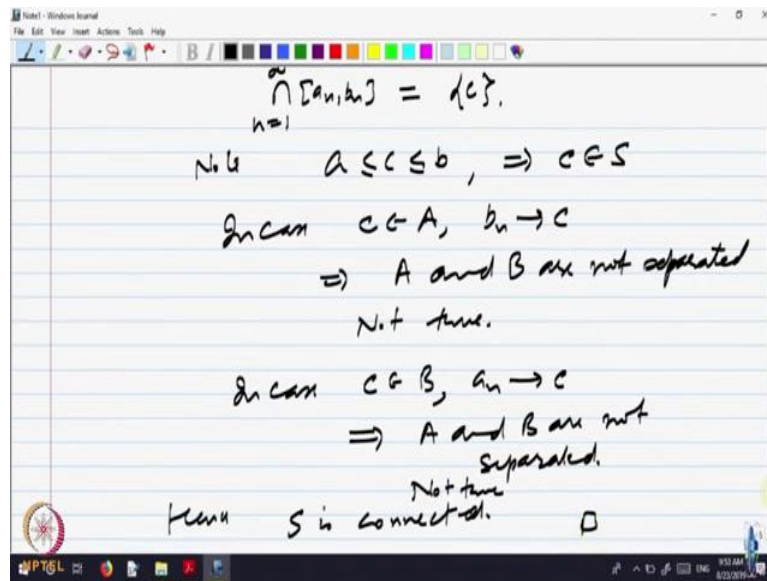

$a_n \in A, b_n \in B$   
and  $(b_n - a_n) \rightarrow 0$  as  $n \rightarrow \infty$

$\Rightarrow$  Nested interval property

$$\bigcap_{n=1}^{\infty} [a_n, b_n] = \{c\}.$$

Note  $a \leq c \leq b, \Rightarrow c \in S$

In case  $c \in A, b_n \rightarrow c$   
 $\Rightarrow A$  and  $B$  are not separated  
N.I. true.

So, let us continue this process, so what does it mean continue I got  $a_1 b_1$  and now I will take the midpoint of  $a_1 b_1$ , both  $a_1$  belongs to  $S$ ,  $b_1$  also belongs to  $S$  so midpoint must belong to  $S$  again. So, whatever we were doing for  $a, b$  I am doing the same thing for  $a_1 b_1$ . So, continue to get  $a_2 b_2$  such that  $a_2$  belongs to  $A$ ,  $b_2$  belongs to  $B$  and the length of  $a_2 b_2$  is equal to half of length of  $a_1, b_1$  which was equal to 1 by fourth length of  $a, b$ .

So, I have got a way of generating smaller interval from  $ab$   $a$  was in  $A$ ,  $b$  was in  $B$  I am able to generate a interval of half the length with a same property left hand point is in  $A$  right hand point is in  $b$  whatever the case may be. So, continuing this process what I will get I will get a sequence of intervals  $A_n, B_n$  which is nested, each one is the previous one, they are closed bounded intervals and the length is going to, what is happening to the length of them?

It is becoming smaller and smaller it is going to 0. So, let us write, so this will give us a nested sequence  $a_n b_n$ , of close bounded intervals such that  $a_n$  belongs to  $A$   $b_n$  belongs to  $B$  for every  $n$  and  $b_n - a_n$  goes to 0 as  $n$  goes to infinity. So, I manufacture a nested sequence of intervals. Now we approach nested interval property of the real line that says there must be a point in the intersection of all of them.

So, imply by nested interval property, intersection of  $a_n b_n, n$  equal to 1 to infinity must be equal to some point let us call it  $c$ . So, obviously  $a \leq c \leq b$  so  $c$  belongs to  $S$ . Because  $a$  and  $b$  both belong  $S$  is a interval, so it must belong. But  $S$  is equal to union of  $A$  union  $B$ .

So, either it will belong to A or it will belong B. So, in case  $c$  belongs to A then what happens what is  $c$  basically. It is the limit of  $b_n$ , so close to  $c$  there will be points of B. So I cannot find a neighbourhood of  $c$  which will be disjoint from B and this is the point in A, but A and B are separated. So that is not possible. In case  $b_n$  converges to  $c$  implies A and B are not separated is that clear?

Because every neighbourhood of  $c$  must have some  $b_n$  after some stage onwards actually all, because  $b_n$  is going to converge. Nested interval property  $b_n$  are right hand points must be converging, the nested sequence, the decreasing sequence, that means there is no neighbourhood of the point  $c$ ,  $c$  is in A which is disjoint from B because  $b_n$  at least will come in. So, A and B are not separated not possible, not true.

So, another possibility is  $c$  belongs to B same thing, now you go to the left hand points and converges to  $c$  implies A and B are not separated, so not true. So, in other case you get a contradiction, so our assumption so what was our assumption? Our assumption was that S can be written as A union B a separation of S is possible we have shown it is not possible that means S is a connected set.

So, implies so let us write hence S is connected. So, we have shown that we have characterize all connected subset of real line a subset of real line is connected if and only if it is an interval. A similar question one can ask for  $\mathbb{R}^n$ , one can prove some theorems will do it later you need more techniques more properties of some other concepts. So, we will later on show for example that in  $\mathbb{R}^n$  what could be a generalisation of interval ball if you take interval then the relation in  $\mathbb{R}^n$  is ball. So, you would expect that every ball is connected at least that much should be true.

So, that can be show on actually, there is a concept called path wise connectedness some geometry comes in, if any two points can be join by a curve in a subset of  $\mathbb{R}^n$ , than that subset is called path connected and one shows every path connected set is also connected, but every connected need not be path connected. So, this kind of things happens. So, slightly more complex slightly more involved to study connected subsets of  $\mathbb{R}^n$  or even in the plane.

So, we will do some examples and some theorems when we come to continuity and such properties of  $\mathbb{R}^n$ , functions. So, for the time being we are doing it only on the real line, so we have. So, till now what we have done is we have looked at subsets of the real line and special properties of those subsets. We started with the real line as a complete ordered field and then

after having done that we looked at what are called intervals, they are some basic open sets called intervals and then we looked at sets, we looked at sequences whether they converge or not when do they converge.

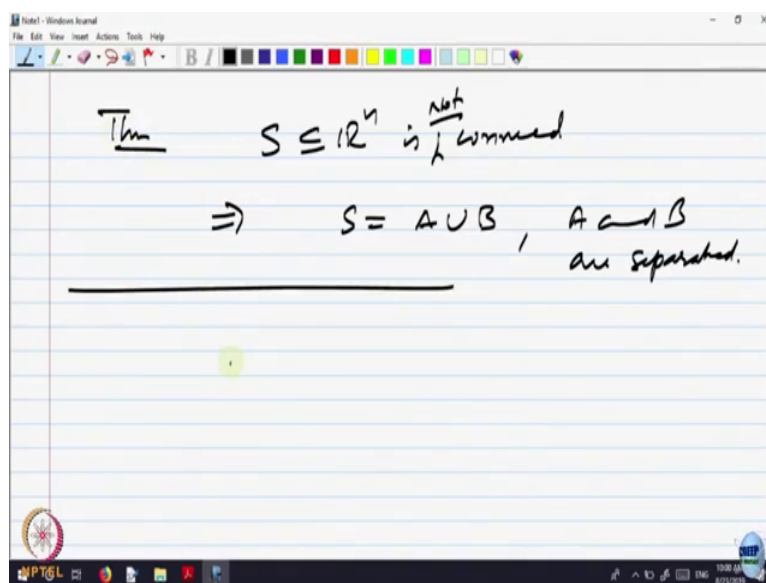

And then we looked at sets which have the property that whenever a sequence of elements converge to some point whether that point is inside the set or not. If all the limits are inside that was called a closed set then we studied some property of closed sets even the set is not closed you can make put it inside a set with its smallest closed subset of real line called the closure and then we define open sets as those sets whose complements are closed.

The set is open if and only if its complement is closed, so concepts property and so on and then we looked at properties of sets which are called compact sets. So, a compact set is something more than a closed set namely a sequence of elements of sets, may not converge but at least there is a subsequence which converges inside the set. So, these are called compact sets, and then we characterize compact sets namely we said every compact set.

A set is compact if and only if it is closed and bounded and then we looked at a characterization of compact sets called Heine-Borel property, that every open cover has got a finite sub cover and that we proved it all if in the real line true for  $\mathbb{R}^n$  and probably you will see if time permits us we will do it later on. All this are, these are concepts, which are also valid in general space is called metric spaces.

So, we will probably introduce, so that also a bit later. For time being let us concentrate on real line and properties of real line. So, we have looked at real line as such sets in real line and special subsets of course we looked at lastly the connected subsets.

(Refer Slide Time: 16:46)

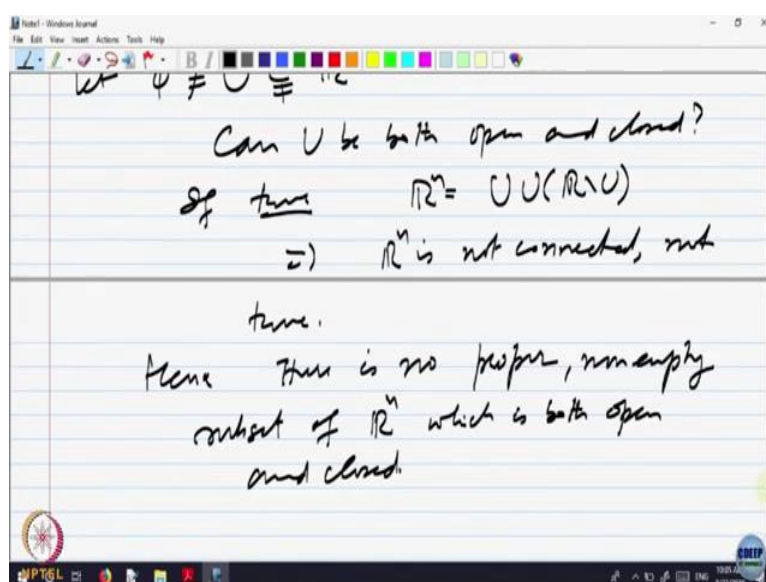

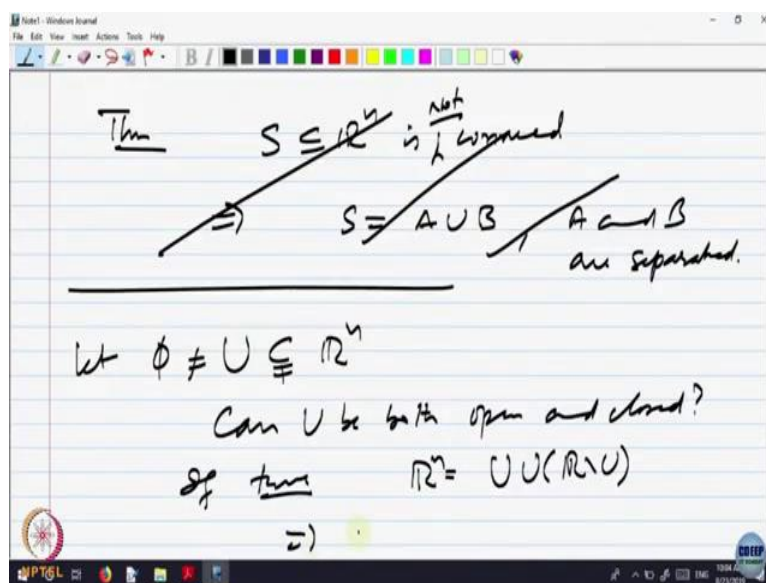

Now here is something very obvious probably I should state that which is good. So, it is true for  $\mathbb{R}^n$  also,  $S$  contained in  $\mathbb{R}^n$  is connected implies. Let us write not connected means what?  $S$  is equal to  $A$  union  $B$ , where  $A$  and  $B$  are separated. Now that separation means what every point of  $A$  has at least a neighbourhood which is completely inside  $A$ , it does not intersect  $B$  because it is separated. So, every point of  $A$  must be open, every point of  $A$  must be open, it was an interior point and hence  $A$  must be an open set.

Every point of  $A$  it is separated from  $B$ , so there must be a open neighbourhood which does not intersect with  $B$ , there is a neighbourhood of which is completely inside  $A$  it does not intersect  $B$ . It does not intersect  $B$ , that does not say it should be inside  $A$  it does not say it is inside so let me revise this statement, so what I am saying is not correct, I have to go to subset actually that is not good idea what I want to say is something need sub spaced topology but let me say a milder version of it.

(Refer Slide Time: 18:44)

Let us take a set  $U$  contained in so forget this one. So,  $U$  is a subset which is non empty and contained in  $\mathbb{R}^n$  let us take. So, let  $U$  be a nonempty subset of  $\mathbb{R}^n$  can  $U$  be a proper subset it is a subset of  $\mathbb{R}^n$  it is not empty so it has at least one element it is not whole of  $\mathbb{R}^n$  then can you be both open and closed? Suppose it is suppose  $U$  is both open and closed then what is real line equal to?

It is  $U \cup U^c$ . If true then  $\mathbb{R}^n$  is equal to  $U \cup (\mathbb{R}^n \setminus U)$ , my claim is this is the separation of  $\mathbb{R}^n$ , why it is a separation of  $\mathbb{R}^n$  because  $U$  is open take any point in  $U$  then there must be a ball inside  $U$ , because  $U$  is open, every point of  $U$  will be inside a ball which is completely inside  $U$ . So,  $U$  is separated from  $U^c$  and same if it is  $U^c$

both open and closed then  $U$  complement is open. So, every point of  $U$  complement is also separated from  $U$  is that clear to everybody.

Definition of openness says every point is a interior point. So, if I give you a point of  $U$  it must be inside a ball which is completely inside  $U$ . So, I will not intersect  $U$  complement that means  $U$  is separated from not only it is disjoint it is actually separated from  $U$  complement, and now let us go to the other way round take a point in  $U$  complement,  $U$  complement is also open, because  $U$  is both open and closed.

So,  $U$  is closed so  $U$  complement is open. So, every point of  $U$  complement will be inside a ball which is completely inside  $U$  complement. So,  $U$  complement also separated from  $U$  for the same reason. That means real  $\mathbb{R}^n$  is not connected because you got a separation. So, conclusion is in  $\mathbb{R}^n$  there is no nonempty proper subset which is both open and closed as a consequence of connectedness.

So, let us write not possible implies  $\mathbb{R}^n$  is nor connected not true because it is a interval. So, hence there is no proper nonempty subset which is both open and closed. So,  $\mathbb{R}^n$  connected implies this kind of property you cannot have subsets which are both open and closed of course non-empty and proper.
