Series of Numbers.

Given $\{a_n\}_{n \geq 1}$, how to add all its elements: What can be $a_1 + a_2 + \dots + a_n + \dots$?

$a_1 + a_2 + \dots + a_n + \dots$?

Def: Given a sequence $\{a_n\}_{n \geq 1}$ of real numbers, let $S_n := a_1 + \dots + a_n, n \geq 1$ it is called the n th partial sum of $\{a_n\}_{n \geq 1}$.

The pair $\{a_n\}_{n \geq 1}, S_n\}$ is called a series of numbers.

The basic idea is, given a sequence a_n , so given a sequence a_n of numbers how to add all its elements. So that is saying that, same as saying what can be a_1 plus a_2 plus, what this quantity can be?

So, to define this properly, let us make a definition. So, given a sequence a_n of real numbers, let us define S_n to be equal to a_1 plus up to a_n , n bigger than 1. So, that is the sum of first n terms of the sequence. So, this S_n , it is called the n th partial sum of the sequence a_n .

So, this is called the n th partial sum and let us give it a name, so the pair, so here is a sequence and here is the partial sum S_n , is called, we will call it a series.

So, a sequence together with its partial sums is called a series of numbers and we say this series, this is a convergent series if, I denote it with small S_n , if S_n limit n going to infinity S_n exists. If we look at the partial sums and take the limit of that, if that limit exists then we say that the series is convergent, and if this limit is equal to S , so S_n we write, $\sum_{n=1}^{\infty} a_n = S.$

Now let us observe, something so that we do not have to write this cumbersome notation of series being this way. That given a sequence a_n , S_n 's are defined, partial sums are defined, so we know S_n 's.

(Refer Slide Time: 04:49)

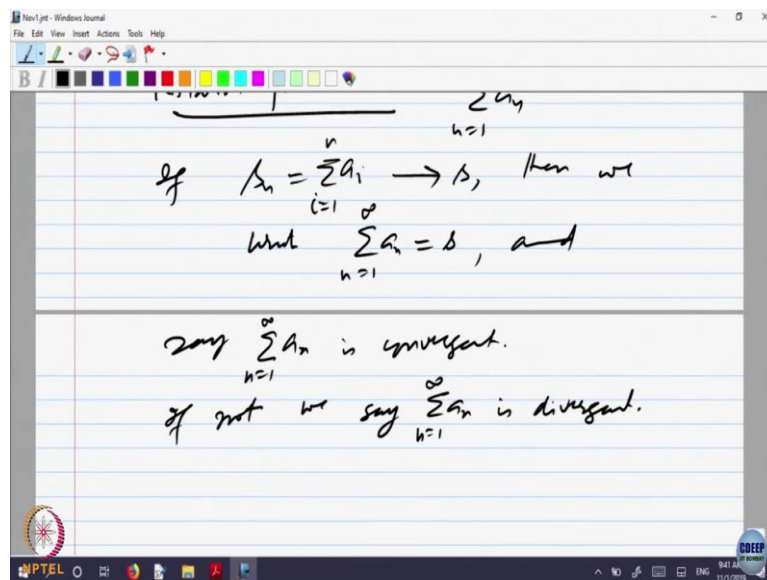

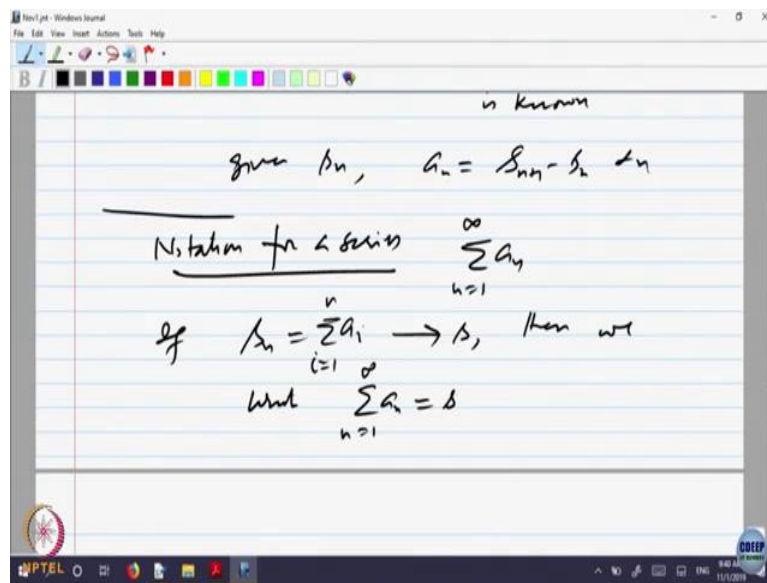

Given $\{a_n\}_{n \geq 1}$, $S_n = a_1 + \dots + a_n$
is known
given S_n , $a_n = S_n - S_{n-1}$ $\forall n$

numbers, let
 $S_n := a_1 + \dots + a_n, n \geq 1$
It is called the n th partial sum of $\{a_n\}_{n \geq 1}$.

The pair $\{\{a_n\}_{n \geq 1}, S_n\}$ is called
a series of numbers.
We say this is a convergent series if
 $\lim_{n \rightarrow \infty} S_n$ exists. If
 $S := \lim_{n \rightarrow \infty} S_n,$

And supposing we say that, we give you the sequence S_n of numbers which is the partial sums of some sequence, then the sequence also is known. So how is that? So, given a_n , S_n which was defined as a_1 plus a_n is known and conversely given S_n 's. What is a_n , that is S_n plus 1 minus S_n for every n . So, giving the sequence or its partial sums that data both are equivalent to each other, you give one data, you get the other data. So, for that reason we do not write all the time a series to be like this. We just, given a sequence a_n .

(Refer Slide Time: 05:44)

So, notation for a series is sigma an. Given a sequence an, we write the corresponding series as this. This does not mean, you should not take as if it says the sum exists. It is just the notation, for that series.

If convergent, so if it is convergent, if the partial sums S_n 's which we defined as sigma i equal to 1 to n ai converges to S then we write sigma an equal to 1 to infinity is equal to S. And say, an is convergent, if not, if it is not convergent we say it is divergent, then we say it is divergent.

(Refer Slide Time: 07:34)

The screenshot shows a presentation slide titled "Series" with a yellow header. The slide content is as follows:

(i) Consider the series

$$\sum_{n=1}^{\infty} a_n, \text{ where } a_n = (-1)^{n+1} \text{ } n \geq 1.$$

Since

$$S_n = 1 \text{ if } n \text{ is even and } S_n = 0 \text{ if } n \text{ is odd,}$$

the sequence $\{S_n\}_{n \geq 1}$ is not convergent. Hence the series is not convergent.

(ii) **Geometric series**
Consider the series

$$\sum_{n=1}^{\infty} r^n, \text{ where } r \in \mathbb{R} \text{ is fixed.}$$

This is called **geometric series** with **common ratio** r . The convergence of this series depends upon the value of the common ratio.

The slide footer includes the text "(Prof. Inder K. Raina, I. I. T. Bombay)", "SI425", and "4 / 97".

Let us look at some examples, they are relatively simple examples. So, let us look at some examples. So, let us look at the series sigma an where the nth term is minus 1 to the power n plus 1 for n bigger than or equal to 1. So, this is a sequence an, what are the terms of the sequence, 1 plus n equal to 1, or so minus 1, minus 1, plus 1, minus 1, plus 1 and so on.

We know that as a sequence this sequence is not convergent, it fluctuates. Let us try to form the partial sum, Sn. So, what will be the partial sum, depends on whether the n is even or odd. So partial sum will be equal to 0 if n is even, the terms will cancel out otherwise it will be minus 1 or plus 1. So, partial sums do not converge. So, we can say that this series minus 1 to the power n plus 1, is not a convergent series by the definition itself. So, this is not convergent series.

The simplest example of a convergent series is the one which we start looking at in our schools, normally called the geometric series. So, what is a geometric series, so it is the series where the nth term an is r to the power n, where r is a fixed real number.

So, take a real number. First term is r, second term is r square and so on. And this number r is called the common ratio because it is a ratio of an plus 1 and an. So, when is it convergent, we all know that is convergent when mod of r is strictly less than 1.

(Refer Slide Time: 09:45)

The screenshot shows a presentation slide with a yellow header titled "Series". The text on the slide reads: "Since $S_n = 1 + r + r^2 + \dots + r^n = \frac{1 - r^{n+1}}{1 - r}$, which converges to $1/(1 - r)$ as $n \rightarrow \infty$; and for $|r| \geq 1$, $\{S_n\}_{n \geq 1}$ is not convergent, The series is convergent if and only if $|r| < 1$ and its sum is $1/1 - r$. We write $\sum_{n=0}^{\infty} r^n = \frac{1}{1 - r}$, $-1 < r < 1$." The slide is displayed in a software window titled "Lecture_series(S425).pdf - Adobe Acrobat Reader DC". The window includes a menu bar (File, Edit, View, Window, Help), a toolbar with navigation icons, and a status bar at the bottom showing the presenter's name "(Prof. Indir K. Rana, I. I. T. Bombay)", the slide number "5 / 97", and the date "11/1/2019".

And why, how is that, what is the proof of that? One can find what is S_n , one can write 1 plus r plus this S_n is equal to 1 minus r to the power n plus 1 over 1 minus r . That is easy to find if you write S_n something multiplied by r , it shifts the powers and subtract and you could easily compute what is S_n .

So, this formula that S_n is equal to 1 minus r to the power n plus 1 over 1 minus r , we do it in our schools but, and it is not difficult to find. And if r , so the question is whether r to the power n plus 1 converges to something or not, as n goes to infinity. And we know, we have done it in sequences that x to the power n converges to 0, if and only if $|x|$ is strictly less than 1.

So, using that fact this is convergent, if and only if $|x|$ is less than 1 and in that case the sum is equal to r to the power n minus 1 will go to 0. So, it is 1 over 1 minus r . So, the simplest example of a series which is convergent and this will be sort of used again and again, a geometric series common ratio is less than 1 is convergent. You will see how, this is one of the building blocks for analyzing series.

(Refer Slide Time: 11:05)

Series

(iii) Consider the series $\sum_{n=1}^{\infty} \frac{1}{n}$. For this

$$S_n = 1 + \frac{1}{2} + \dots + \frac{1}{n} \text{ for every } n \geq 1.$$

For $n = 2^k$, we have

$$\begin{aligned} S_{2^k} &= 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots + \frac{1}{2^{k-1}} + \frac{1}{2^{k-1}+1} + \dots + \frac{1}{2^k} \\ &= 1 + \frac{1}{2} + \left(\frac{1}{2^2-1} + \frac{1}{2^2}\right) + \dots + \left(\frac{1}{2^{k-1}-1} + \dots + \frac{1}{2^k}\right) \\ &> 1 + \frac{1}{2} + \left(\frac{1}{2^2} + \frac{1}{2^2}\right) + \dots + \left(\frac{1}{2^k} + \dots + \frac{1}{2^k}\right) \\ &= 1 + \frac{k}{2}. \end{aligned}$$

This shows that $\{S_{2^k}\}_{k \geq 1}$ is an unbounded sequence.

Let us look at one more example, let us look at S_n equal to 1 over n . The first one was, minus 1 plus 1 and now it is 1 over n . So, what is S_n , S_n is 1 plus 1 by 2 plus up to 1 by n , and the terms are non negative. So, it seems S_n is going to increase, you are adding more and more non negative numbers. So, S_1 is 1 , and S_2 is equal to 1 plus half so on, so something is increasing.

But the question is how much does it increase? Because if the partial sums S_n 's are increasing, we know it is increasing, but if it is bounded then they will converge, by the property of real numbers. So, is it bounded or not bounded, if it is not bounded above then it will not converge. So, to analyze that one has to make some estimates.

So, let us look at, for n equal to 2 to the power k , let us compute this quantity. So n to the, 2 to the power k . So, this is the 1 , plus 1 by 2 and so on over 1 to 2 to the power k and now you pair up. See, 1 over 4 is 1 over 2 square 1 over 3 is 1 over 2 square minus 1 . So, make this pairing and 2 to the power k is even. So, you can pair up.

Once you pair up, now this quantity 1 over 2 square minus 1 , it is bigger than, if I increase the denominator it is bigger than 1 over 2 square. So, I get bigger than, I do it everywhere, and this is 2 by 2 square and k by 2 to the power k . So, this is bigger than 1 plus k by 2 .

So, these kinds of estimates one has to do, to analyze a series. So, what we are saying is for n equal to 2 to the power k , the sum S_{2^k} is 1 plus k by 2 . So, what happens to these partial sums for n equal to 2 to the power k , as k goes to infinity. It is bigger than k by 2 , so it goes to infinity.

So, at least for the partial sums we have got a sub sequence, when n is equal to 2 to the power k. The partial sums has a sub sequence which goes to infinity, is non negative, so it is not bounded above. So, there is a sub sequence which is not bounded above of partial sums. So, the sequence itself cannot be bounded above.

So, sequence of partial sums is not convergent because it is non negative, it is not bounded above. For given any n, you can always find 2 to the power k such that S to the power, such that 2 to the power k is bigger than n.

Given any natural number n, you can always find k, such that 2 to the power k is bigger than n, that increases faster than n, you can easily prove that. So, S to the power 2, S partial sum up to 2 to the power k will be bigger than the partial sum up to n. So, that also will go to infinity. So, that shows it is not bounded, so it is not convergent. So, what does it imply, it implies that the series, 1 over n is not convergent. This is how by definition itself alone we are trying to analyze. Because it is non negative we can make estimates.

(Refer Slide Time: 15:25)

The screenshot shows a presentation slide with the following content:

Series

Thus, $\{S_n\}_{n \geq 1}$ is also unbounded and hence not convergent. Hence, the series $\sum_{n=1}^{\infty} \frac{1}{n}$ is not convergent. The series $\sum_{n=1}^{\infty} \frac{1}{n}$ is known as the **harmonic series**.

(v) Consider the series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n}$$

It is called the **alternating harmonic series**. Let us look at the odd and even terms of $\{S_n\}_{n \geq 1}$, the sequence of partial sums of the series. For any k

$$S_{2k} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots - \frac{1}{2k}$$

$$= \left(1 - \frac{1}{2}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \dots + \left(\frac{1}{2k-1} - \frac{1}{2k}\right)$$

The slide footer includes the name (Prof. Inder K. Rana, I. I. T. Bombay), the slide number (S1425), and the page number (7 / 97).

Let us do one more estimation like this, this is interesting. We had 1 over n, let us look at, so the series 1 over n is called harmonic series because of a different reason.

Let us consider the harmonic series, but now the terms are coming plus and minus; so minus 1 to the power n plus 1 divided by n, so it starts with n equal to 1. It is 1 minus 1 by 2 plus 1 by 3 and so on, alternative. Let us try to find out, whether the partial sums for this converge or not, somewhere. So, let us make some estimates.

Once again as before let us try to look at n equal to $2k$. So, n equal to $2k$, look at the partial sums up to the terms $2k$, I think there is something wrong here. This is not 2 to the power $2k$, it is just $2k$, so there is a typo here. Now how many terms are there, even number of terms, $2k$, so I am taking the sums of first $2k$ terms first. So, I can pair them.

So, the first one, 1 , so what I am doing is I am pairing up, so that it is sum of non negative terms, 1 minus 1 by 2 plus 1 by 3 minus 1 by 4 and so on. So, I have grouped them in $2, 2$ a pairing. And 1 by 3 minus 1 by 4 , that is non negative. So, each bracket is a non negative number.

So, S to the, what does it tell you about these partial sums, that for n equal to $2k$, the partial sums are increasing. Because each bracket is non negative, and k plus 1 , one more bracket will come, some non negative thing will be added up. So, S_{2k} is a sequence of non negative real numbers. Let us see, what happens when it is odd.

(Refer Slide Time: 17:53)

Series

Similarly, we can write

$$S_{2k+1} = 1 - \left(\frac{1}{2} - \frac{1}{3}\right) - \left(\frac{1}{4} - \frac{1}{5}\right) - \dots - \left(\frac{1}{2k} - \frac{1}{2k+1}\right).$$

From these, it follows that $\{S_{2k}\}_{k \geq 1}$ is monotonically increasing while $\{S_{2k+1}\}_{k \geq 1}$ is monotonically decreasing. Further

$$0 < S_{2k} < S_{2k} + \frac{1}{2k+1} = S_{2k+1} \leq 1.$$

Hence, by the completeness property of real numbers, both the sequences $\{S_{2k}\}_{k \geq 1}$ and $\{S_{2k+1}\}_{k \geq 1}$ are convergent. In fact, the relation also tells us that they have the same limit. Hence, the sequence $\{S_n\}$ is also convergent. Note that we have not found its sum.

So, let us compute the same thing, for $2k$ plus 1 . So, S_{2k} plus 1 , one more term will be added there. So, what is relation between them, S_{2k} plus 1 over $2k$ plus 1 , that is equal to S_{2k} plus 1 . One more term is added there and it is plus here, because $2k$ plus 1 is odd, so minus 1 to the power n plus 1 it was. So, this is a relation between $2k$ and $2k$ plus 1 .

So, if I look at this sequence of $2k$ and $2k$ plus 1 , what is a difference between these 2 , this one is increasing S_{2k} , S_{2k} plus 1 when I pair them up, what can you say about the sequence S_{2k} plus 1 ? 1 minus something, minus again something, I am subtracting and each bracket is non negative.

So, more and more things are being subtracted. So $S_{2k} + 1$ is decreasing as k increases but S_{2k} is increasing and this is relation between them, S_{2k} is less than $2k + 1$ and all are bounded between 0 and 1.

So, what does it imply, S_{2k} is increasing and bounded, so that will converge. $S_{2k} - 1$ that also is decreasing is a monotonous sequence, bounded below so that also will converge, so both of them converge. And what is the difference between the 2, between this S_{2k} and $S_{2k} + 1$, the difference is 1 over $k + 1$, so the difference can be made as small as you want. So, the sequence of partial sums, the even partial sums and the odd partial sums both converge to the same value. We have got a sequence, where the odd and the even both converge, the sub sequence of odd terms and the sub sequence of even terms both converge to the same value.

So, here is an exercise show that a sequence itself is convergent. So, take it as an exercise in sequences. You have got a sequence an of numbers, such that if I take the sub sequence of even, so a_2, a_4, a_6 that sub sequence and look at the sub sequence a_1, a_3 and so on, both converge to the same value. Then claim, that the sequence itself should converge to that value, the sequence itself is convergent. It is a very small exercise, it is a good exercise to go back and revise your notion of sequences, just definition.

So that will mean what, what will that mean, odd and even both converge so the sequences themselves converge. So that means, S_n is convergent, S_n itself is convergent that was the exercise we were seeing, and as a result this series is convergent.

So, the interesting thing is the series 1 over n is not convergent, but 1 to the power n plus 1 , divided by n , that is a convergent series, alternate plus and minus terms if you make it, that is called the alternating harmonic series.

(Refer Slide Time: 21:52)

Series

Thus, $\{S_n\}_{n \geq 1}$ is also unbounded and hence not convergent. Hence, the series $\sum_{n=1}^{\infty} \frac{1}{n}$ is not convergent. The series $\sum_{n=1}^{\infty} \frac{1}{n}$ is known as the **harmonic series**.

(v) Consider the series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n}.$$

It is called the **alternating harmonic series**. Let us look at the odd and even terms of $\{S_n\}_{n \geq 1}$, the sequence of partial sums of the series. For any k

$$\begin{aligned} S_{2k} &= 1 - \frac{1}{2} + \frac{1}{3} - \dots - \frac{1}{2k} \\ &= \left(1 - \frac{1}{2}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \dots + \left(\frac{1}{2k-1} - \frac{1}{2k}\right). \end{aligned}$$

(Prof. Inder K. Rana, I. I. T. Bombay) SI425 7 / 97

So that is called, so this series, this series is called alternating harmonic series. That is convergent. So, I am just giving you some examples to illustrate that how definition can be used to prove something is convergent or not. And it becomes slightly cumbersome every time estimating the partial sums and trying to see whether it is convergent or not. So, these are the examples which illustrate that.

(Refer Slide Time: 26:00)

Series

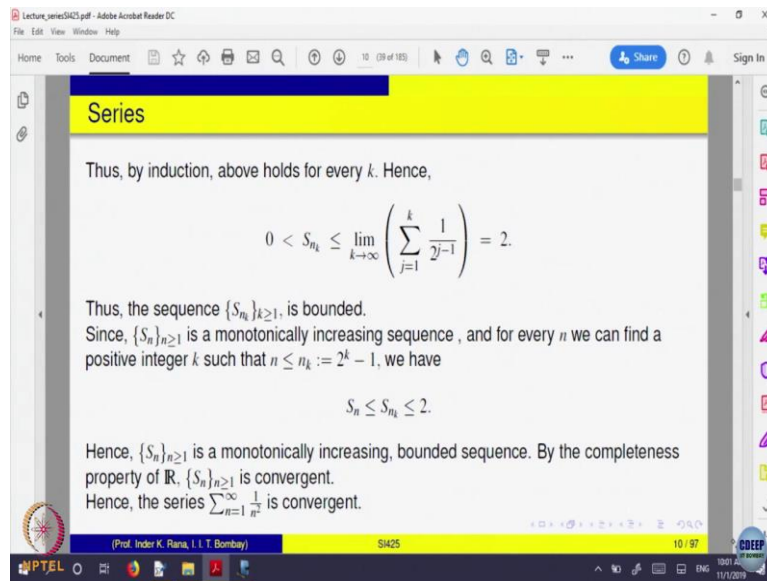

(vi) Consider the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$. Since it is a series of positive terms, the sequence $\{S_n\}_{n \geq 1}$ of partial sums is a monotonically increasing sequence. Let $n_k := 2^k - 1$, $k \geq 1$. Then, we claim that for every k ,

$$0 < S_{n_k} \leq 1 + \frac{1}{2} + \dots + \frac{1}{2^{k-1}}. \quad (1)$$

Clearly, $S_{n_1} = 1$ and if above holds for n_k , then

$$\begin{aligned} S_{n_{k+1}} &= S_{n_k} + \left(\frac{1}{(2^k)^2} + \frac{1}{(2^k+1)^2} + \dots + \frac{1}{(2^{k+1}-1)^2}\right) \\ &< 1 + \frac{1}{2} + \dots + \frac{1}{2^{k-1}} + \frac{2^k}{(2^k)^2} \\ &= 1 + \frac{1}{2} + \dots + \frac{1}{2^{k-1}} + \frac{1}{2^k}. \end{aligned} \quad (2)$$

(Prof. Inder K. Rana, I. I. T. Bombay) SI425 9 / 97

So naturally, let us look at one more, probably, 1 over n square. So, the series is nth term is 1 over n square. This is a series of non-negative terms. 1 over n square is nonnegative. So, partial sums will be a monotonically increasing sequence of numbers. The question is whether it is bounded above or not. If it is bounded above, the partial sums then the series will converge, if not then it will diverge.

Again, let us try to estimate. The claim is that, if I look at nk which is 2 to the power k minus 1, then S_{n_k} is less than equal to sum of the geometric series, 1 by 2 plus 1, 1 by 2, 1 by 2 cube and so on. So, we are trying to bring in somewhere again, something known kind of a thing, and this proof for every k we want to prove something.

So, what is the technique of proving something for every natural number, the only thing we know is by induction. So apply induction, S_{n_1} is equal to 1, so it is true, n_k plus 1. So, what will be it, that is S_{n_k} plus something, plus the remaining terms which are being added, and that squares, $2k$ squares.

So, you can make it less than, 1 over 2 to the power k is less than 1 over 2 and so on. So, this becomes less than the geometric series. So, estimates basically. So, once you do that, once you know this is true, so what happens to the series S_{n_k} , it is less than this. And this is a convergent series, we know that.

So, what happens to the limit, as k goes to infinity, the geometric series. It was bounded by the geometric series, so we know the sum of n terms, and goes to infinity. So, what we are saying is there is a sub sequence n_k , there is a subsequence n_k of partial sums S_n 's which are bounded between 0 and 2.

Can you say that, that implies S_n itself is bounded? What is n^k , what was n^k , n^k was 2 to the power k minus 1. We were saying that if I take n to be, n^k to be this then S_n is bounded. Can we claim that S_n itself is bounded? Keep in mind they are non negative.

Once again, given any n , given any n you can find a k , such that n is less than n^k . Given any natural number n , you can find a power of 2 to the power k , such that n is less than 2 to the power k minus 1.

Yes or no? Yes? Natural numbers, 2 to the power, they are going to increase faster than n anyway, much faster. So that means what, and they are non negative terms. So given any n , there is a k such that n is less than n^k .

Can I say S_n is less than S of n^k , yeah because they are non negative terms. S_n is increasing, and that is bounded by 2, so each S_n is bounded by 2. Each partial sum is bounded by 2, because the sequence of partial sums is monotonically increasing and for n equal to 2 to the power k minus 1, it is bounded by 2. And coupled this with the fact that, given any n , you can find a natural number k , such that n is less than 2 to the power k minus 1.

So, S_n will be less than the partial sum up to 2 to the power k minus 1 which is less than 2. So, each S_n is bounded by 2, it is monotonously increasing so they will be convergent. Because they are non negative, so 1 over n square is a convergent series.

So, this is convergent, monotonically increasing and bounded so it is convergent. Here what was helping us is because it is series of non negative terms, partial sums are monotonously increasing we have to only analyze whether they are bounded above or not.
