The screenshot shows a presentation slide with a yellow header and a white body. The header contains the title "Simple tests of convergence". The body contains two bullet points, a theorem, an equation, and a proof. The bullet points are: "The sum of a convergent series is unique." and "Dropping finitely many terms from a series does not alter convergence or divergence, although it may change the sum of a convergent series." The theorem is: "Theorem (Cauchy criterion): A series  $\sum_{n=1}^{\infty} a_n$  is convergent if and only if for every  $\epsilon > 0$ , there exists  $N \in \mathbb{N}$  such that  $|S_m - S_n| = |x_{n+1} + \dots + x_m| < \epsilon$  for every  $m > n > N$ ." The proof states: "Proof: This is just a restatement of the fact that  $\sum_{n=1}^{\infty} a_n$  is convergent if and only if  $\{S_n\}_{n \geq 1}$ , the sequence of partial sums is Cauchy." The slide is displayed in a window titled "Lecture\_series(SI425).pdf - Adobe Acrobat Reader DC".

So, here is a, keep in mind one thing, the sum of convergent series is always unique. If a series is convergent its sum is unique. Why, limit of a sequence is unique. What is definition of sum, it is the limit of partial sums, and partial sums can converge only to one limit. So, limit of a convergent sequence is unique that implies, that sum of a convergent series is unique.

Suppose, you drop some of the terms from a,  $a_1, a_2, \dots, a_n$  is a sequence given. I want to know that whether it is summable from 1000 terms onwards or not. That is equivalent to saying whether it is, the series itself is convergent or not, because what is left is the sum of finite terms only. So, if, so you can say the convergence of a series does not depend upon first few terms of the series.

It is the same as the fact that we did for sequences. Convergence of a sequence depends only on what is the tail of the sequence; so, convergence or divergence of series does not depend on the first few terms, whether those are added in the series or not. But the sum may change. If you sum it from 1 to onwards or 1000 onwards, the sum may change. But convergence or divergence will not depend upon, it depends only on the tail of sequence  $a_n$  which is given.

Cauchy's criteria, which is a consequence of, a sequence is convergent if and only if it is Cauchy. A series is convergent when these partial sums converge, and partial sums will converge only when the partial sums is a Cauchy sequence.

So coupled with that fact, the Cauchy criteria, that sequence  $a_n$  is convergent if and only if partial sums is Cauchy and that is same as saying given epsilon. You can write epsilon delta, epsilon n naught definition, given epsilon, the difference between the nth and the mth term should be small and that is that sum from mod of  $x_n$  plus 1 to  $x_m$  should be small, for  $m$  bigger than  $n$ ,  $S_m$  minus  $S_n$  that should be small. So, there is nothing, it is a simple consequence of the fact that every sequence, a sequence is convergent if and only if it is Cauchy. So, apply it to the partial sums.

(Refer Slide Time: 03:21)

**Series**

**Corollary ( $n^{\text{th}}$ -term test):**

If a series  $\sum_{n=1}^{\infty} a_n$ , is convergent, then

$$\lim_{n \rightarrow \infty} a_n = 0.$$

(ii) If

$$\lim_{n \rightarrow \infty} a_n \neq 0,$$

then the series  $\sum_{n=1}^{\infty} a_n$ , is divergent.

(iii) If

$$\lim_{n \rightarrow \infty} a_n = 0,$$

then the series  $\sum_{n=1}^{\infty} a_n$ , may either converge or diverge.

say  $\sum_{n=1}^{\infty} a_n$  is convergent.  
 if not we say  $\sum_{n=1}^{\infty} a_n$  is divergent.

---

$$\sum_{n=1}^{\infty} a_n, \quad S_n = a_1 + \dots + a_n$$

$$S_{n+1} - S_n = a_{n+1} \quad \text{--- } \otimes$$

if  $\sum a_n$  is convergent, then  $\otimes$

$$\Rightarrow 0 = \lim_{n \rightarrow \infty} a_{n+1} = \lim_{n \rightarrow \infty} a_n$$

Now here is another simple fact that, suppose a series is convergent, then what is the  $n$ th term? If a series is convergent what is the  $n$ th term? This is a series, whether convergent or not, let us not bother.  $S_n$  is a partial sum, then what is  $S_{n+1} - S_n$ , that is  $a_{n+1}$ , simple arithmetic.

Now if,  $\sum a_n$  is convergent then, in this left hand side if I take the limit  $n$  going to infinity. Then star implies what? What is the limit of the left hand side? Series is given to be convergent.

Then what is the left hand side, that is  $0$  is equal to  $\lim_{n \rightarrow \infty} (S_{n+1} - S_n)$ . And if you like, this is same as  $\lim_{n \rightarrow \infty} a_{n+1}$ , does not matter. Or I could have just written here,  $S_n - S_{n-1}$ , I could have written, that is equal to  $a_n$ , either way.

So, I get a consequence, very simple observation that if a series is convergent then the  $n$ th term in that sequence, the sequence of  $n$ th term must go to  $0$ . So,  $a_n$  must go to  $0$ . So, this gives me a necessary condition for a series to be convergent.

A series is convergent, then it should necessarily happen that the  $n$ th term should become smaller and smaller and go to  $0$ . So, that is a necessary condition and a very useful one because if the  $n$ th term does not go to  $0$ , then the series cannot converge. So, not convergence is useful proving.

So that is same as saying, if  $a_n$  is not equal to  $0$  it is divergent. But if it is, it is only necessary condition, it is not sufficient. That means, if the  $n$ th term goes to  $0$  that does not imply that the series will always converge.

Remember, just now we said  $1/n$  series is not convergent,  $n$ th term is  $1/n$  that goes to  $0$ . But the alternating series again the  $n$ th term goes to  $0$ , but that is convergent. So, this is not the sufficient condition that the  $n$ th term should go to  $0$ , it is only necessary. It may be either converge or diverge. So, you can give examples we just now given.

You can apply, if you like you can apply it geometric series, we proved for  $|r| < 1$  or  $|r| > 1$ ,  $n$ th term will not go to  $0$  if  $|r| > 1$ , it goes to infinity so that does not converge.

(Refer Slide Time: 07:25)

The screenshot shows a presentation slide with a yellow header titled "Series". Under the heading "Examples:", there are two items:

- (i) Consider the geometric series  $\sum_{n=1}^{\infty} r^n$ , where  $|r| > 1$ . Since,  $|r|^n \rightarrow \infty$ , the series  $\sum_{n=1}^{\infty} r^n$  is not convergent.
- (ii) Consider the series 
$$\sum_{n=1}^{\infty} \left( \frac{n^2 + n + 3}{2n^2 + 1} \right).$$
 Since, 
$$\lim_{n \rightarrow \infty} \left( \frac{n^2 + n + 3}{2n^2 + 1} \right) = \lim_{n \rightarrow \infty} \left( \frac{1 + \frac{1}{n} + \frac{3}{n^2}}{2 + \frac{1}{n^2}} \right) = \frac{1}{2} \neq 0,$$
 the series is not convergent.

The slide footer includes the name "(Prof. Inder K. Rana, I. I. T. Bombay)", the course code "SI425", and the slide number "14 / 97".

So, let us look at this kind of a series. It looks like  $n^2 + 3n + 1$  divided by  $2n^2 + 1$ . It looks like the numerator and denominator both are increasing, at the same rate essentially,  $n^2$ , power is  $n^2$ .

So, when  $n$  goes to infinity it will stabilize somewhere, because both are increasing at the same rate. How do I analyze that, so look at the  $n$ th term,  $n$ th term is  $n^2 + 3n + 1$  divided by  $2n^2 + 1$ ; I want to analyze what happens as  $n$  goes to infinity. So, the simplest thing is divide numerator and denominator by  $n^2$ , because I know  $1$  over power of  $n$  goes to  $0$ .

So that gives you  $1$  plus, numerator will give you  $1 + \frac{1}{n} + \frac{3}{n^2}$ , and the denominator will give you  $2 + \frac{1}{n^2}$  as  $n$  goes to infinity the limit will be equal to, numerator will go to  $1$ , denominator goes to  $2$ . So, by the theorems on sequences, if an is convergent,  $bn$  is convergent, and  $bn$  is not convergent to  $0$  then  $\frac{an}{bn}$  is convergent to  $\frac{\lim an}{\lim bn}$ .

So that theorem says, that the limit of this  $n$ th term of this series is converging to  $\frac{1}{2}$ , which is not equal to  $0$ . So, this series cannot converge, because the  $n$ th term does not go to  $0$ . So,  $n$ th term that is how it is used to say, analyze not convergent of a series. So, this does not converge.

(Refer Slide Time: 09:36)

The screenshot shows a presentation slide titled "Algebra of Series". The text on the slide is as follows:

**Theorem :**  
Let  $\sum_{n=1}^{\infty} a_n$  and  $\sum_{n=1}^{\infty} b_n$  be series and  $c \in \mathbb{R}$ . Then the following hold:

(i) If  $\sum_{n=1}^{\infty} a_n$  and  $\sum_{n=1}^{\infty} b_n$  are convergent, then

$$\sum_{n=1}^{\infty} (a_n + b_n), \sum_{n=1}^{\infty} (a_n - b_n), \sum_{n=1}^{\infty} (a_n b_n) \text{ and } \sum_{n=1}^{\infty} (c a_n)$$

are all convergent and

$$\sum_{n=1}^{\infty} (a_n + b_n) = \sum_{n=1}^{\infty} a_n + \sum_{n=1}^{\infty} b_n, \quad \sum_{n=1}^{\infty} (a_n - b_n) = \sum_{n=1}^{\infty} a_n - \sum_{n=1}^{\infty} b_n,$$

and

$$\sum_{n=1}^{\infty} (c a_n) = c \left( \sum_{n=1}^{\infty} a_n \right).$$

Now, here are the theorems about algebra of limits, giving you algebra of convergent series. If  $a_n$  is a series which is convergent,  $b_n$  is a series which is convergent you can add  $n$ th term of both, get a new series whose  $n$ th term is  $a_n + b_n$ .

Then what will be the partial sums of  $a_n + b_n$ , it will be partial sum of  $a_n$  plus partial sums of  $b_n$ . And if  $a_n$  is convergent then partial sums converges, so partial sums of the sum will converge to sum of the partial sums by limit theorems on sequences.

So, if  $a_n$  is convergent,  $b_n$  is convergent then,  $a_n + b_n$  is convergent and sum is equal to sum of  $a_n$  plus sum of  $b_n$ , because of the limit theorems on sequences. Same logic applies to the other, you can have difference; you can have the scalar multiplication. One can wonder what happens if you multiply 2 series.

Can you multiply two series? Does not matter, you can just look at  $a_n b_n$  if you want, that is one way of multiplication. But the partial sums will not be multiplication of partial sums, so that will not work out. So, it is only for the additions. One can think what could be way of multiplying series so that the corresponding result for series is valid. You understand what I am, I am throwing a question.

What could be, given a series  $a_n$ , given a series  $b_n$ , what could be the multiplication of these 2 series so that the limit of that product whatever we define is product of the sums. Think of it, it is a good thing to think. It is possible to do such things, but let us not do into that.

So, this is algebra of the sums of the convergent series, this is for convergent only. If  $a_n$  is convergent, if  $b_n$  is convergent, then  $a_n + b_n$ , that series is also convergent, using the sequences, theorems on sequences. How is that useful, you can always make examples.

(Refer Slide Time: 12:04)

**Series**

**Example:**

(i) Consider the series

$$\sum_{n=1}^{\infty} \left( \frac{2}{3^n} + \left( \frac{3}{4} \right)^n \right).$$

Since it is a sum of two convergent series:

$$\sum_{n=1}^{\infty} \frac{2}{3^n} \text{ and } \sum_{n=1}^{\infty} \left( \frac{3}{4} \right)^n,$$

it is also convergent.

(Prof. Inder K. Rana, I. I. T. Bombay) SI425 17 / 97

**Series**

(ii) Consider the series

$$\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} \left( \frac{5}{2^n} + \frac{2}{n} \right).$$

This is a divergent series, for if it were convergent, then

$$\sum_{n=1}^{\infty} \left( \frac{2}{n} \right) = \sum_{n=1}^{\infty} a_n + \sum_{n=1}^{\infty} \left( \frac{5}{2^n} \right)$$

would also be convergent, which is not true.

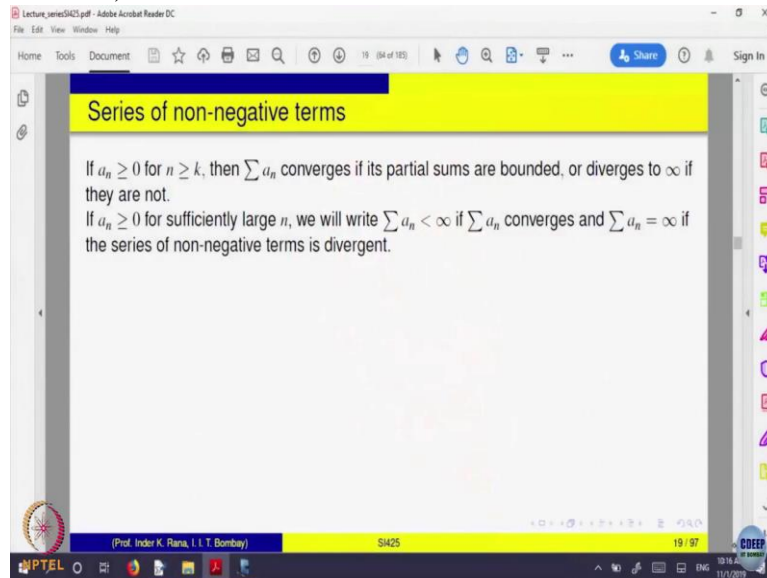

Here is another simple test that can be used for analyzing convergence of series with nonnegative terms.

(Prof. Inder K. Rana, I. I. T. Bombay) SI425 18 / 97

Look at this series, 2 by 3 to the power n plus 3 by 4 whole to the power n, is it convergent? So, we will sum up 2, so 2 over 3 raised to 1 over 2 by 3 raised to power n and you try to show that both of them are convergent and the sum will be the sum of that. So, I am leaving for you to check why both are convergent.

More examples one can give, I think. This is not convergent, why, because if it were, I know 5 by this is convergent when you subtract it should give me 2 by n should be convergent which is not true. So, one can play with this kind of things. The usefulness of saying that sum of convergent series is convergent.

(Refer Slide Time: 13:27)

Here is something. So let us, what I am going to do is I am going to specialize for some time on series with non negative terms only, an's are all nonnegative. When an's are non negative partial sums are going to be increasing, partial sums are going to be increasing.

Because we will be adding something all the time non negative. So, either the series will converge if the partial sums are bounded above or what will happen, the partial sums will keep on increasing and go to plus infinity.

So, in some, in such case when sequences of non negative terms are given, series of non negative terms, if convergent we write what is the sum or sigma an less than infinity. Other only other possibility is, it is divergent and, in that case, partial sums converge to plus infinity, so one writes sigma an 1 to infinity equal to plus infinity. That is the notation, nothing more than that. So, it is just a notation saying that they are...

(Refer Slide Time: 14:58)

The screenshot shows a presentation slide with a yellow header and footer. The header contains the title "Series of non-negative terms". The main content includes a theorem statement: "Theorem (Comparison test): Let  $\{a_n\}_{n \geq 1}$  and  $\{b_n\}_{n \geq 1}$  be sequences of real numbers such that  $0 \leq a_n \leq b_n$  ultimately, i.e., there exists some  $N \in \mathbb{N}$ , such that  $a_n \leq b_n$  for every  $n \geq N$ , then, the following hold: (i) If the series  $\sum_{n=1}^{\infty} b_n$  is convergent, then so is the series  $\sum_{n=1}^{\infty} a_n$ . (ii) If the series  $\sum_{n=1}^{\infty} a_n$  is divergent, then so is the series  $\sum_{n=1}^{\infty} b_n$ ". The footer contains the name "(Prof. Indir K. Rana, I. I. T. Bombay)", the slide number "54/25", and the time "20:57".

So, here is, one of the simplest tests which can help us to analyze convergence or divergence of a series. We are given 2 sequences of non negative terms  $a_n$  and  $b_n$ , such that  $a_n$  is less than  $b_n$ . Ultimately, what does ultimately mean, from some stage onwards, ultimately means for some stage onwards because it is the tail that is going to matter for convergence. So, you can write ultimately, that is for some  $n$  bigger than capital  $N$ ,  $a_n$  is less than or equal to  $b_n$ . So that means what, each term of the sequence  $b_n$  is dominating the term  $a_n$  from some stage onwards.

So, what will happen to the partial sums, partial sum of  $a_n$  will be dominated by the partial sums of the series  $b_n$ . Because  $a_n$  is less than  $b_n$ . So, if the partial sums of  $b_n$ 's converge, partial sums of  $a_n$ 's are dominated by partial sums of  $b_n$ , so that will converge because it is less than or equal to. And if  $a_n$ 's do not converge, then  $b_n$ 's cannot converge, because  $a_n$ 's are less than  $b_n$ .

So, you get 2 ways of writing it. Just writing the partial sums of the corresponding things, that if  $b_n$ 's have converged, if the series  $b_n$  is convergent then the series  $a_n$  is also convergent. Because the partial sums of  $a_n$ 's, will be less than or equal to partial sums of  $b_n$  and that converges so no problem.

And because  $a_n$  is less than  $b_n$ , if  $a_n$  is divergent, that means what, the partial sums go to infinity. Partial sums of  $b_n$  are bigger than partial sum of  $a_n$ , so  $b_n$ 's also will, partial sums of  $b_n$  also will go to infinity. So, it implies that if  $a_n$  is divergent then  $b_n$  is divergent, if  $b_n$  is convergent then  $a_n$  is also convergent. Simple comparison of 2 series, from stage onwards an

is less than  $b_n$ . Very simple proof, so no problem about that. So, let us skip the proof. Try to write the proof yourself. What will be involved?

(Refer Slide Time: 17:59)

Let me just write probably one, so that you understand why some minor modifications are required. So, we have got an less than equal to  $b_n$  for every  $n$ , for every  $n$  or for some stage onwards, that does not matter, from some stage onward.

So, what is  $S_n$  equal to,  $a_1$  plus  $a_2$  plus  $a_n$  will be less than or equal to  $b_1$  plus  $b_2$  plus  $b_n$  and that is, that is  $S_n$  of this, what should I write for  $S_n$  of that, some notation, so let me write  $S_n$  dash. We are calling that as  $S_n$  dash, we are calling it as  $S_n$ . So, this implies this. So,  $S_n$  dash convergent implies  $S_n$  convergent. Why? How should I justify? How should I justify this statement?

Student: (())(19:18)

Professor: These are partial sums only,  $S_n$  is partial sum, this is a partial sum.

Student: (())(19:23) we can write

Professor: We can write this, this is okay. But I am saying this imply, so this statement implies convergent is, or hence  $S_n$  dash convergent implies  $S_n$  convergent. Why is that?

Student: (())(19:39)  $b_n$ 's itself are convergent.

Professor:  $b_n$ 's are not convergent.

Student: The series  $S_n$ , the series  $b_n$  is convergent.

Professor: Series  $b_n$  is convergent is same as saying this is convergent. So, this is because series  $b_n$  is convergent. Why does it imply  $\sum S_n$  is convergent, you have to say something more.

Student: Because they are bounded.

Professor: Bounded by what?

Student: Partial sums of  $(\frac{1}{n})$  (20:14)

Professor: Partial sums, this partial sum is less than or equal to partial sum that. So, the claim is  $S_n$  is convergent, why? What is the reason,  $S_n$  is a sequence of numbers. Why is it convergent?

Student: It is bounded by limit of  $S_n$  prime.

Professor:  $S_n$  prime

See both are non negative terms. So,  $S_n$  dash is increasing. So, limit of  $S_n$  dash will dominate all  $S_n$ 's, limit of  $S_n$  dash will dominate all  $S_n$ 's. And  $S_n$  itself is also increasing, is non negative terms, so partial sums are again increasing. So, this is also increasing sequence of non negative terms which is bounded above and hence it must converge, so we are using both things.

Professor: If a sequence of, if a sequence is monotonically increasing and convergent, so what is the limit?

Student: Upper bound

Professor: Limit is upper bound, least upper bound.

So, all  $S_n$ 's dash for every  $n$  is less than or equal to the upper bound which is the limit, which exists. So,  $S_n$ 's are bounded, monotonically increasing, so they converge. So that is the argument that we have to supply in between.

And similarly, if we want to say that  $a_n$ 's are,  $\sum a_n$  is divergent, that means what, that the partial sums  $S_n$ 's are converging to infinity, and  $S_n$  is less than  $S_n$  dash. So,  $S_n$  dash will also converge to infinity because they are bigger than  $S_n$  and  $S_n$  is going to infinity. So, if  $a_n$  is divergent then,  $b_n$  also is divergent; simple observations about sequences only. So that is the comparison test. So, let us skip the proof of that.

(Refer Slide Time: 22:34)

Series

Examples:

(i) Consider the series

$$\sum_{n=1}^{\infty} \frac{1}{n^p} \text{ where } 0 \leq p < \infty.$$

For  $0 \leq p \leq 1$ , since

$$n^p \leq n \text{ for every } n \geq 1,$$

and the series  $\sum_{n=1}^{\infty} \frac{1}{n}$  is divergent,  
the series

$$\sum_{n=1}^{\infty} \frac{1}{n^p} \text{ is divergent for } 0 \leq p \leq 1.$$

(Prof. Indir K. Rana, I. I. T. Bombay) S425 23 / 97

So, let us look at examples of comparison test. So, we are comparing 2, so look at the series. Remember we did 1 over n; that was divergent, 1 over n square was convergent. So now, we are looking at for any p between, bigger than 0, less than infinity, what can you say about that. So, let us assume, so it depends on p of course. Because p is equal to 1, we know it is divergent. So, let us look at when p is between 0 and 1 then n to the power p, is less than or equal to n, because p is between 0 and 1.

So, what happens to 1 over np, that is bigger than, 1 over that will be bigger than 1 over n. And 1 over n is divergent. So, 1 over np will be divergent, the sigma 1 over np is divergent for p between 0 and 1 by comparison test, comparing it with 1 over, the series 1 over n. Simple observation. So, that is divergent, so this is divergent between 0 and 1.

Let us look at when p is bigger than 2, we know 1 over n square was convergent, p was equal to 2. So, let us take p bigger than or equal to 2. What happens to np and n square?

(Refer Slide Time: 24:34)

The screenshot shows a presentation slide with a yellow header titled "Series". The text on the slide reads: "For  $p \geq 2$ , since  $n^p \geq n^2$  for  $n \geq 2$  and the series  $\sum_{n=1}^{\infty} \frac{1}{n^2}$  is convergent, the series  $\sum_{n=1}^{\infty} \frac{1}{n^p}$  is convergent for  $n \geq 2$ . We shall prove a bit later that  $\sum_{n=1}^{\infty} \frac{1}{n^p}$  is convergent to  $p > 1$ ." Below this, it says "(ii) Consider the series" followed by the equation 
$$\sum_{n=1}^{\infty} \left( \frac{1}{2n^2 + n + 1} \right)$$
 and then "Since  $\frac{1}{2n^2 + n + 1} < \frac{1}{n^2}$  for every  $n \geq 1$  and the sum  $\sum_{n=1}^{\infty} \frac{1}{n^2}$  is convergent, the given series is also convergent." The slide footer includes the name "(Prof. Indir K. Rana, I. I. T. Bombay)", the ID "SI425", and the slide number "24 / 97".

If  $p$  is bigger than 2, compare  $n$  to the power  $p$  and  $n$  to the power 2,  $n$  square,  $n$  to the power  $p$  will be bigger than  $n$  square. So, convergence of  $1$  over  $n$  square will give you convergence of  $1$  over  $n$  to the power  $p$  for  $p$  bigger than or equal to 2. Already proved convergence of  $1$  over  $n$  square, already proved divergence of  $1$  over  $n$ , comparison gives you, for  $p$  between 1 and 0,  $np$  is divergent for  $p$  bigger than or equal to 2,  $1$  over  $np$  sigma  $np$  is convergent.

Between 1 and 2, we have not done anything yet. Because we are just, known things, we have to compare with something known,  $a_n$ ,  $b_n$ ,  $a_n$  less than or equal to  $b_n$ . If you know something about  $b_n$  convergent then you can say  $a_n$  convergent, sigma  $a_n$  convergent, we will do that also a bit later.

For example, let us look at this kind of a thing. So how these things help us analyzing,  $1$  over  $2n$  square plus  $n$  plus 1 kind of thing. It looks like  $1$  over  $n$  square, it looks like  $1$  over  $n$  square. So, can we compare  $1$  over  $2n$  square plus  $n$  plus 1 with  $1$  over  $n$  square?  $n$ th term? Already  $2n$  square, we are increasing the denominator, so making it smaller anyway.

So,  $1$  over  $2n$  square plus  $n$  plus 1, that you call as  $a_n$  is less than,  $1$  over  $n$  square which is  $b_n$ , that is convergent so this is convergent. So, how you think and what you have to compare with, that you have to sort of keep in mind. So, this is convergent. I think there are more examples you can study later on.

(Refer Slide Time: 26:19)

More tests of convergence

**Lemma:** Let  $\{a_n\}_{n \geq 1}$  and  $\{b_n\}_{n \geq 1}$  sequences of positive real numbers such that

$$\ell := \lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right) \text{ exists.}$$

(i) If  $\ell \neq 0$ , then there exist a positive scalars  $\alpha, \beta$  and  $n_0 \in \mathbb{N}$  such that

$$\alpha b_n \leq a_n \leq \beta b_n \text{ for all } n \geq n_0.$$

(ii) If  $\ell = 0$ , then

$$0 < a_n < b_n \text{ for all } n \geq n_0.$$

(Prof. Indir K. Rana, I. I. T. Bombay) 5425 26 / 97

Let us look at, something which requires a bit of thought but not much. Suppose, is again a kind of comparison but we are going to look at, see we looked at that  $1/2n^2$  and all that, and  $1/n^2$ . So,  $2n^2$  and  $n^2$  sort of compatible kind of a thing, we could compare.

So here, we are looking at  $a_n$  and  $b_n$ , 2 sequences, of positive real numbers, only for the time being positive and look at the limit of that, suppose that limit exists. Suppose, the limit exists and is 1. So, what is the meaning of saying this 1 exists,  $a_n/b_n$ , that means eventually  $a_n$  and  $b_n$  are stabilizing. They are becoming, sort of coming to a common kind of, proportion kind of a thing.

So, the claim is if this limit exists and if this limit is not equal to 0, then you can have inequality which says for some  $\alpha$  and  $\beta$ ,  $\alpha b_n \leq a_n \leq \beta b_n$  if this limit is not equal to 0. In what way that is useful, it helps you to compare  $a_n$  and  $b_n$ . It says from some stage onwards, you can compare  $a_n$  and  $b_n$ .

So, convergence of one can imply the convergence of other or the divergence of one can imply the divergence of the other. So, this limit becomes important. And if this, so let us look at first why is this thing happening.

(Refer Slide Time: 28:15)

$$\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right) = l \neq 0$$

$$\text{If } \epsilon > 0, \text{ choose } \delta > 0 \text{ s.t. } l - \epsilon > 0.$$

$$\text{Then } \exists n_0 \text{ s.t. } \frac{a_n}{b_n} \in (l - \epsilon, l + \epsilon) \forall n > n_0$$

$$\text{If } \epsilon > 0, \text{ choose } \delta > 0 \text{ s.t. } l - \epsilon > 0.$$

$$\text{Then } \exists n_0 \text{ s.t. } \frac{a_n}{b_n} \in (l - \epsilon, l + \epsilon) \forall n > n_0$$

$$\alpha = l - \epsilon < \frac{a_n}{b_n} < l + \epsilon = \beta$$

$$\alpha b_n < a_n < \beta b_n$$

So, I want to look at a simple, you see analysis of real line is coming back to picture. So, an divided by  $b_n$  limit  $n$  going to infinity equal to  $l$  and that is not equal to  $0$ . So, here is  $0$ , here is  $l$ , either on positive side or on the negative side, does not matter, it is away from  $0$ . So, what is the meaning of saying that its limit exists, limit exists means the terms should come in the neighborhood of that point after some stage onwards.

So, let us define neighborhood like this. Say  $l$  minus epsilon and  $l$  plus epsilon. So, let us choose epsilon such that, so if  $l$  is bigger than  $0$  choose such that  $l$  minus epsilon is also bigger than  $0$ , then convergence there exists some  $n$  naught, such that  $a_n$  by  $b_n$  belongs to  $l$  minus epsilon and  $l$  plus epsilon for every  $n$  bigger than  $n$  naught. That is simple convergence.

It comes in a neighborhood. I want to stay away from 0, so I will just take 1 minus. So, what does that mean, that means 1 minus epsilon is less than an by bn is less than 1 plus epsilon. Call this number as alpha, call this number as beta. So, then alpha times bn is less than an is less than beta times bn, you got the inequality. Simple definition of limit, if limit is not 0, an over bn should stay away from 0, that is all.

And if this limit is equal to 0 will mean what? So, this was 1 bigger than 0. Similarly, 1 less than 0, does not matter, bigger or, 1 is bigger than 0, if it is less than 0, what would be your argument.

Say if 1 is here, if 1 is here then you will have 1 plus epsilon and then you will choose epsilon size that 1 plus epsilon is bigger than 0. Here we had taken this, in this case we will choose epsilon such that 1 plus epsilon is bigger than 0, so everything will be inside this. Again, this will be your alpha, that will be your beta.

Student: (( ))(31:27) positive, then how can 1 be less than 0?

Professor: Pardon?

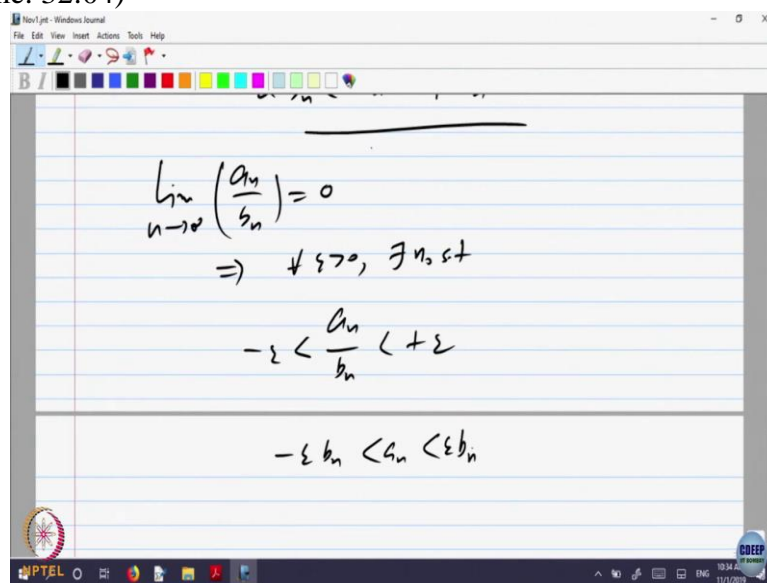

Student: a and b are positive sequences

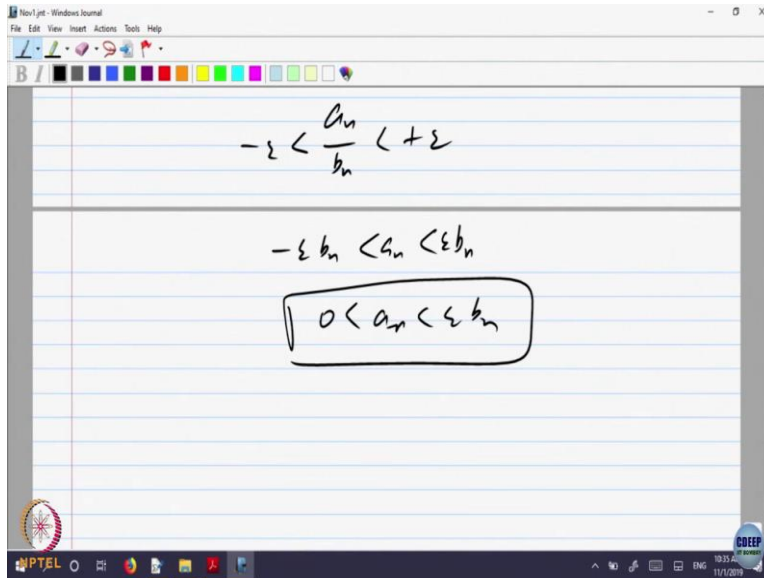

Professor: They are positive, I am saying this...

Student: If they are negative.

Professor: So, it is a valid point. I am just giving you general arguments. For any sequence, an and bn, not necessarily positive, in our case, in other case this does not matter. But in general I am saying the limit of a sequence, if it is not 0 then everything should be in the neighborhood of, away from 0.

(Refer Slide Time: 32:04)

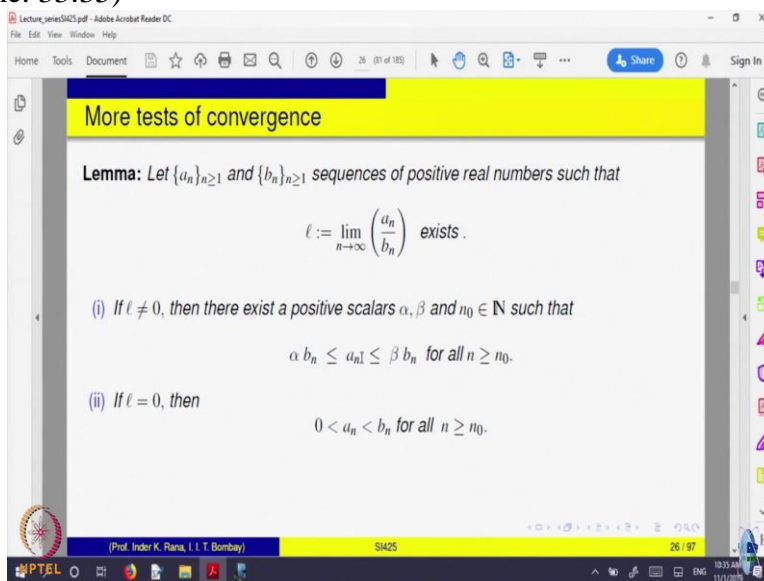

Now, if the limit is equal to 0 that is possible. So, let us say that limit of  $a_n$  by  $b_n$  is equal to 0, that means what? By the same argument, then there exists, so for every epsilon bigger than 0 there is a  $n$  naught, such that  $a_n$  by  $b_n$  between minus epsilon and plus epsilon, in neighborhood of 0. So, that means what, minus epsilon  $b_n$  is less than  $a_n$  is less than  $a_n$  plus epsilon,  $b_n$  times,  $b_n$  times epsilon.

But  $a_n$ , in our case all the  $a_n$ 's are non negative, so 0 less than  $a_n$  less than epsilon  $b_n$ , because all the  $a_n$ 's are non negative. So, if the limit is 0 now you get only one inequality  $a_n$  and less than or equal to  $b_n$ . But still it gives you a comparison between  $a_n$  and  $b_n$ , you can compare  $a_n$  with  $b_n$ . So, that was the lemma.

(Refer Slide Time: 33:35)

Now, you can use this lemma in view of the comparison test. So, what will that give me, if the limit is not equal to 0, of this thing and supposing  $b_n$  is convergent then look at this, this part of the inequality,  $a_n$  less than or equal to the beta times  $b_n$ ,  $b_n$  is convergent so that will

imply,  $a_n$  is convergent. And other way round, if  $a_n$  is convergent I can use this part to say  $b_n$  is convergent.

So, if the limit is not equal to 0 of  $a_n$  by  $b_n$  then either both  $a_n$  and  $b_n$  converge or both diverge. If  $\sum a_n$  is convergent, then  $\sum b_n$  is convergent and other way round. If the limit is equal to 0 then only convergence of  $b_n$  can apply, convergence of  $a_n$  or divergence of  $a_n$  can apply divergence of  $b_n$ , it will not give you if and only if.

The idea is that comparison test, when you want to find the sum of a series, it is only some point onwards the things matter. How are we getting this? Saying that  $1 - \epsilon$ ,  $1 + \epsilon$ ,  $a_n$  by  $b_n$  is important for  $n$  bigger than or equal to  $n_0$ . So, this comparison is valid only for, and that is good enough for convergence.

(Refer Slide Time: 35:25)

The screenshot shows a presentation slide with a yellow header "More tests of convergence". The main text reads: "Theorem: (Limit Comparison test): Let  $\sum_{n=1}^{\infty} a_n$  and  $\sum_{n=1}^{\infty} b_n$  be series of positive terms such that  $\ell := \lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  exists." Below this, two cases are listed: (i) "If  $\ell \neq 0$ , then  $\sum_{n=1}^{\infty} a_n$  is convergent if and only if  $\sum_{n=1}^{\infty} b_n$  is convergent." and (ii) "If  $\ell = 0$  and  $\sum_{n=1}^{\infty} b_n$  is convergent, then  $\sum_{n=1}^{\infty} a_n$  is also convergent." The slide footer includes "Prof. Inder K. Rana, I. I. T. Bombay", "SI425", and "28 / 97".

So, that gives me that test which is limit comparison test. So, either  $\sum a_n$  is convergent if and only if  $\sum b_n$  is convergent. If limit is 0, when  $b_n$  is convergent implies  $a_n$  is convergent. So, how this test helps in analyzing series of non negative terms that is important.
