Chinese Remainder Theorem the Initial Cases

Welcome back. We are discussing about solving the system of simultaneous linear congruences. So I told you that this, the corresponding result the main result in this theory is called the Chinese Remainder Theorem. Remainder of course stands for the a_i 's that we have. So, what we are really looking for is a number x such that whenever you divide by n_i the remainder should be a_i , this is the problem.

And the first occurrence until now is in the third century AD and that was from China and that is why it is called Chinese remainder theorem.

(Refer Slide Time: 01:02)

Simultaneous linear congruences: The first occurrence seems to be in a book by Sun-Tzu Suan-Ching in the third century AD.

$$n \equiv 2 \pmod{3}, n \equiv 3 \pmod{5} \text{ and } n \equiv 2 \pmod{7}.$$

And the answer is: $n \equiv 23 \pmod{105}$.

$$105 = 3 \times 5 \times 7 = \text{lcm}(3, 5, 7).$$

So as we can read it here it is in a book by Sun-Tzu Suan-Ching and the problem was an elaborate problem, but in the mathematical lingo this translates as asking for a solution for a natural number n which is congruent to 2 mod 3. So when you take out groups of 3 what is left is 2 it is 3 mod 5. So when you take out groups of 5 what is left is 3 and finally it is 2 mod 7.

So we solved this in the last lecture and we observed that the solution is 23 you can of course add 105 to it so you have that 128 is also a solution. We just observe here that the number 105 is obtained as the product of these 3 moduli. The modulus 3 into the modulus 5 into the

modulus 7 this is what we have. In general this is actually going to be replaced by what is called the LCM of these 3 numbers.

At the moment since these 3 numbers are pair wise co-prime therefore their LCM is nothing but their product. But when we see a general theory maybe 2 lectures on or 3 lectures later we will see that this product is going to be replaced by the LCM. So this is the statement of the theorem so statement that we have seen the problem and its solution let us now go towards the statement of the theorem.

It is an important theorem I am going to show it to you line by line and let us try to understand each line correctly.

(Refer Slide Time: 02:55)

Chinese Remainder Theorem:

Let $n_1, n_2, \dots, n_k \in \mathbb{N}$, with $(n_i, n_j) = 1$ for each $i \neq j$.

Let $a_1, a_2, \dots, a_k \in \mathbb{N}$. Then the system

$$x \equiv a_1 \pmod{n_1}, x \equiv a_2 \pmod{n_2}, \dots, x \equiv a_k \pmod{n_k}$$

has a unique solution modulo $n = n_1 n_2 \cdots n_k$.

So we start with n_1, n_2, n_k these are natural numbers and the condition on them is that n_i, n_j is 1 whenever you have i not equal to j . So that means that pair wise these integers are co-prime this is the only condition and that is why and using only this condition we are going to get our result. So we have k tuple of natural numbers consisting of pair wise co-prime integers.

We start with any k tuple of integers a_1, a_2, a_k so here there is no condition and now we ask for the solution of the system x congruent to $a_1 \pmod{n_1}$, x congruent to $a_2 \pmod{n_2}$ so on up to x congruent to $a_k \pmod{n_k}$. So, we want one single natural number which when we take out multiples of n_1 common will give you the remainder a_1 . When you take out multiples of n_2

out gives you the remainder a_2 and so on up to k th stage where you are taking multiples of n_k out the remainder is a_k .

Once again note that there is no condition on a_1, a_2, a_k . The only condition is on n_1, n_2, n_k and the condition is that they be pair wise co-prime. Meaning if I take n_1 and n_2 then there is no common factor n_1, n_3 have no common factor so on up to n_1, n_k have no common prime factor then n_2, n_3 have no common prime factor n_2, n_4 have no common prime factor n_2, n_k have no common prime factor.

And the last pair that you will get is $n_k - 1$ and n_k those two natural numbers also have no common prime factor. This is the only condition we have then this system has a unique solution we are not saying that there is a solution we even say that it has a unique solution modulo the product n which is n_1, n_2, n_k this is the statement that we have we will prove this statement the proof is actually quite simple.

But there is one basic idea in the proof and so we will do some of the simpler cases of this theorem where k is 2 and k is 3 and then we will do the general result, but before doing any such thing you may wonder whether there are any applications of this result meaning number theory is it used to be the branch of mathematics which had no applications and Professor G. H. Hardy whose name has come up once before when I told you about the method of contradictions he had a book an Apology of a Mathematician.

So in the same book he also says that he is quite proud of the fact that number theory has no applications. So he was of the opinion that one should study only for the purpose of studying, it should not get clouded by these materialistic ambition. So he would say that you should not look at applications, you should study because the theory is beautiful, you should study because you like it.

So number theory used to be one such thing but ofcourse now with the advance of cryptography and so on there are plenty of applications of number theory, but let us go and look at one application of this particular theorem the Chinese remainder theorem and the application is as follows it is in astronomy. So the application is as follows.

(Refer Slide Time: 06:37)

Applications in astronomy: If k events occur regularly, with periods n_1, n_2, \dots, n_k , with the i -th event happening at the time $x = a_i, a_i + n_i, \dots$, then the k events occur simultaneously when

$$x \equiv a_i \pmod{n_i} \quad \text{for all } i.$$

If the periods n_i are pairwise coprime then such an x can be found.

This may have been the motivation behind the CRT

Consider the situation where you have k events occurring regularly and the periods are n_1, n_2, \dots, n_k . So there are these k events which occur regularly this event can be anything. So it can be a solar eclipse or lunar eclipse or I do not know if you remember, but when I was a child this there was this comet called Halley's Comet and apparently this comet which circulates the solar system will come back and go pass through a distance which is closest to Earth every 76 years.

So there are these astronomical events and many of them are periodic events there is some nice definite periodicity which one can compute and so here we assume that there are these k events which occur regularly with these period n_1, n_2, \dots, n_k . So if you had the first event occurring at some time then the next time it would occur would be at so suppose you are with the i th event happening at the time x equal to a_i .

So, suppose you have started counting with the Gregorian calendar and then in 2020 some event occurs and then the period of this thing occurring again we say 35 years. So in 2055 it will occur again so that is what we have as a_i and then $a_i + n_i$ and then it would continue occurring regularly with respect to those period. So you have these k events occurring regularly with periods n_i and we assume that $a_i, a_i + n_i$ and so on these are the times when they are occurring.

So when you go modulo n_i the occurrence is x congruent to a_i this is what we have and then you would ask for the simultaneous occurrence of this. This was an event which was of

interest to astronomers when some particular set of events occur simultaneously. So this is solvable when you have these congruence moduli n_i to be co-prime.

So if these periods n_i happened to be pair wise co-prime then ofcourse such an x can be found and the ancient people of possibly all civilizations knew about this result and this is one event which could even be the motivation behind studying the Chinese remainder theorem. I believe that it could be one of the motivations behind the Chinese remainder theorem.

So what we are looking here is that when you have these k events occurring regularly with periods n_i the first one occurring at a_i then a_i plus n_i and so on then the occurrence is the simultaneous occurrence would be given by a solution to the simultaneous the system of simultaneous congruences x congruent to $a_i \pmod{n_i}$ for all i and if these n_i are pair wise co-prime then ofcourse you can simply write down and find the solution.

Many times in various proofs the solution is proved only up to existence, but we will see that with some techniques we can actually construct a solution. So now we are going to prove the Chinese remainder theorem let us walk through this proof together it is a simple proof, but there is one key idea so once you understand this key idea then the proof really becomes transparent.

(Refer Slide Time: 10:17)

Proof of the CRT:

Consider the case $k=2$. $(n_1, n_2)=1$.

$$x \equiv a_1 \pmod{n_1}, \quad x \equiv a_2 \pmod{n_2}.$$

particular case!

$$\left. \begin{array}{l} x_1 \equiv 1 \pmod{n_1}, \quad x_1 \equiv 0 \pmod{n_2} \\ x_2 \equiv 0 \pmod{n_1}, \quad x_2 \equiv 1 \pmod{n_2} \end{array} \right\} \text{if these are found then}$$

$$x = a_1 x_1 + a_2 x_2 \equiv \begin{cases} a_1 + a_2 \cdot 0 = a_1 \pmod{n_1} \\ a_1 \cdot 0 + a_2 \cdot 1 = a_2 \pmod{n_2} \end{cases}$$

So, let us begin this proof what we are going to do to begin with is to consider the case k equal to 2. So what we are asking for is that we are interested in finding a solution to this system. Here of course we have n_1 and n_2 to be co-prime. So we are looking at pair wise co-

prime and here we have a single pair. So we are asking that whenever n_1 and n_2 are co-prime do we have a solution to this.

Now here we are once again I will remark that we are looking at a_1, a_2 to be any tuples any pairs of natural numbers, but I will first try to get solution for this particular tuple. So I am asking for solution for x_1 congruent to $1 \pmod{n_1}$ and x_1 congruent to $0 \pmod{n_2}$ and another system where I am asking for the solutions to this. So I am looking at two particular cases so these two are particular cases of the above problem.

But if we have a solution to these so if these are found then I will simply take x to be $a_1 x_1$ plus $a_2 x_2$. So, assuming that there is a solution x_1 and x_2 satisfying these various conditions with the assumption we can solve a general equation. So if you are going modulo n_1 then here x_1 is $0 \pmod{n_2}$ and a_2 is x_2 is $1 \pmod{n_2}$. So, let us look at this modulo both n_1 and n_2 . So when I am going modulo n_1 modulo n_1 (a_1) x_1 is 1.

So this is going to be a_1 times 1 plus a_2 times 0 and therefore it gives me a_1 and similarly for x_2 we are going to get a_1 modulo n_2 . Modulo n_2 means we have to look at this particular part. So from here we see that modulo n_2 x_1 is 0 so I will get $a_1 \pmod{n_2} 0$ plus $a_2 \pmod{n_2} x_2$ which is 1 and therefore we get it to be a_2 . So once we have solution to these two particular cases then we are able to solve the equation. So we go to the next page and solve these two particular cases.

(Refer Slide Time: 14:28)

Proof of the CRT (Contd.): $(n_1, n_2) = 1$

$$\left. \begin{array}{l} x_1 \equiv 1 \pmod{n_1}, \quad x_1 \equiv 0 \pmod{n_2} \\ x_2 \equiv 0 \pmod{n_1}, \quad x_2 \equiv 1 \pmod{n_2} \end{array} \right\} \begin{array}{l} \leftrightarrow n_2 | x_1 \\ \leftrightarrow n_1 | x_2 \end{array}$$

$x_1 = n_2 k_1, \quad x_2 = n_1 k_2$, now we solve for

$$n_2 k_1 \equiv 1 \pmod{n_1}, \quad n_1 k_2 \equiv 1 \pmod{n_2}$$

Such k_1, k_2 can be found as $(n_1, n_2) = 1$.

So we have n_1, n_2 equal to 1 and we are now going to solve for x_1 congruent to 0 sorry x_1 is congruent to 1 mod n_1 and x_1 is 0 mod n_2 and when we look at x_2 we demand that this be 0 mod n_1 and x_2 be congruent to 1 mod n_2 , but this second condition is equivalent to n_2 dividing x_2 and this n_2 dividing x_1 and this condition is n_1 dividing x_2 .

So what we get is that x_1 is of the type $n_2 k_1$ and x_2 is $n_1 k_2$ and so now we have to solve $n_2 k_1$ which is x_1 congruent to 1 mod n_1 and x_2 which is $n_1 k_2$ congruent to 1 mod n_2 and such case k_1, k_2 can be found as n_1, n_2 is 1. So let us go through this proof once again. What we are asking for is to solve these two special cases x_1 which has the property that it is 1 mod n_1 and 0 mod n_2 and x_2 has the property that it is 0 mod n_1 and 1 mod n_2 .

And we saw in the last slide that when you have solutions to such an x_1 and x_2 you can solve for a general x by simply putting it as $a_1 x_1$ plus $a_2 x_2$ gives a general solution. This is something that we have seen. So we want to solve only for these two special cases of our system of simultaneous congruences and then this immediately told us x_1 congruent to 0 mod n_2 says that n_2 has to divide x_1 .

And therefore x_1 is of the form n_2 times some k_1 and similarly x_2 congruent to 0 mod n_1 will tell you that x_2 has to be of the form n_1 times k_2 . So, the congruence x_2 congruent to 0 mod n_1 is solved because we are looking at x_2 to be only multiples of n_1 . So by looking at we have solved this particular congruence the only congruence that remains to solve is this x_2 congruent to 1 mod n_2 .

Similarly by taking x_1 to be a multiple of n_2 this congruence is solved and so we have to only solve the first congruence which is x_1 congruent to $1 \pmod{n_1}$ so those things are now encoded here. So this is x_1 congruent to $1 \pmod{n_1}$ x_2 congruent to $1 \pmod{n_2}$, but n_1 and n_2 are co-prime and we know from the system of solution of a linear congruence that when you have GCD of the coefficient of x and the modulus dividing the constant term then you have a solution and the number of solutions is exactly the GCD.

Here you have n_1, n_2 are coprime so the GCD is 1 therefore you get a solution and since the GCD is 1 your solution is unique modulo that n_1 , but anyway the uniqueness will come later. We at least have a solution for x_1 and solution for x_2 by having computed k_1 and k_2 so when we deal with some particular problems we will need to compute these k_1 and k_2 .

So k_1 has the property that multiplied to n_2 it gives you $1 \pmod{n_1}$ and k_2 has the property that multiplied to n_1 you get $1 \pmod{n_2}$. So once you solve this then you have a system then you have a solution to the simultaneous system of linear congruences. Let us do one more case we want to generalize these two k events, we want to generalize these two k tuple n_1, n_2, n_k let us do it for 3 and then we go on to do the general case.

(Refer Slide Time: 20:10)

Proof of the CRT (Contd.): $(n_1, n_2) = (n_1, n_3) = (n_2, n_3) = 1$.

$$x \equiv a_1 \pmod{n_1}, \quad x \equiv a_2 \pmod{n_2}, \quad x \equiv a_3 \pmod{n_3}.$$

$x_1 \equiv 1 \pmod{n_1},$	$x_1 \equiv 0 \pmod{n_2},$	$x_1 \equiv 0 \pmod{n_3},$
$x_2 \equiv 0 \pmod{n_1},$	$x_2 \equiv 1 \pmod{n_2},$	$x_2 \equiv 0 \pmod{n_3},$
$x_3 \equiv 0 \pmod{n_1},$	$x_3 \equiv 0 \pmod{n_2},$	$x_3 \equiv 1 \pmod{n_3}.$

Then $x = a_1 x_1 + a_2 x_2 + a_3 x_3$ is a solution.

$$\equiv 0 + 0 + a_3 = a_3 \pmod{n_3}$$

So here we have n_1, n_2 equal to n_1, n_3 equal to n_2, n_3 which is 1 and we are looking for solutions to x congruent to $a_1 \pmod{n_1}$ x congruent to $a_2 \pmod{n_2}$ and x congruent to $a_3 \pmod{n_3}$. Once again like the last time we are going to look at three special cases. Our first special case is x_1 which is congruent to $1 \pmod{n_1}$, but it is $0 \pmod{n_2}$ and $0 \pmod{n_3}$. This is our first

special case x_2 is the one which has congruence 1 when you divide by when you go modulo by n_2 and otherwise you get 0.

And finally we have x_3 which will give you 0 when you divide by n_1 it will give you 0 when you divide by n_2 , but it will give you 1 when you divide by n_3 and then once you have a general solution then x which is $a_1 x_1$ plus $a_2 x_2$ plus $a_3 x_3$ is a solution because when I go modulo n_1 so let us do this for one congruence at a time.

So this is going to be if I am going modulo n_1 then modulo n_1 x_1 is 1, so I will get a_1 , x_2 is 0 so I do not get anything for a_2 , x_3 is 0 so I do not get anything for a_3 . So this is the congruence when I go modulo n_1 which is what we wanted. We wanted to have x to be $a_1 \pmod{n_1}$. Now suppose we want to do it for n_3 instead of n_2 so the similar things would work for all the other moduli.

Suppose I want to go mod n_3 so I have to look at this particular column of congruences. So x_1 is $0 \pmod{n_3}$ therefore $a_1 x_1$ will give me 0 x_2 is $0 \pmod{n_3}$ so $a_2 x_2$ this will give you a_2 times 0 and finally x_3 is 1 so I get a_3 times 1 which is simply $a_3 \pmod{n_3}$ and this is what we wanted to obtain. So these three very special systems of simultaneous linear congruence will give you a general solution to a system of simultaneous linear congruences.

So now we have to solve for each of these three. So x_1 congruent to $1 \pmod{n_1}$ and $0 \pmod{n_2, n_3}$, x_2 congruent to $1 \pmod{n_2}$ and $0 \pmod{n_1, n_3}$ and x_3 congruent to $1 \pmod{n_3}$ and $0 \pmod{\text{the first two } n_1, n_2}$ this is to be solved.

(Refer Slide Time: 24:27)

Proof of the CRT (Contd.): $(n_1, n_2) = (n_1, n_3) = (n_2, n_3)$

$$\underline{x_1 = (n_2 n_3) k_1 \equiv 1 \pmod{n_1}, \quad C_1 = n_2 n_3, (C_1, n_1) = 1}$$

$$\underline{x_2 = (n_1 n_3) k_2 \equiv 1 \pmod{n_2}, \quad C_2 = n_1 n_3, (C_2, n_2) = 1}$$

$$\underline{x_3 = (n_1 n_2) k_3 \equiv 1 \pmod{n_3}, \quad C_3 = n_1 n_2, (C_3, n_3) = 1}$$

Since $(C_i, n_i) = 1$ for all i , we have a solution k_i to the above congruences and hence $k=3$ case is done.

So let me just write it here again that we have these three to be co-prime and we are looking at. So because x_1 is $0 \pmod{n_2}$ and x_1 is $0 \pmod{n_3}$ we have that x_1 is n_2, n_3 times a k_1 and we want to solve for $1 \pmod{n_1}$. So we have these n_2, n_3 then we look at x_2 which is n_1, n_3, k_2 because we would have that x_2 is $0 \pmod{n_1}$ and $0 \pmod{n_3}$, but $1 \pmod{n_2}$. So x_2 is divisible by n_1 and n_3 .

So we have x_2 to be $n_1, n_3 k_2$ congruent to $1 \pmod{n_2}$ and finally we will solve for x_3 to be n_1, n_2, k_3 which we ask to be congruent to $1 \pmod{n_3}$. So all these numbers that we have in the bracket so call C_1 to be product n_2, n_3 C_2 to be the product n_1, n_3 and C_3 to be the product n_1, n_2 then we observe that C_1 and n_1 are co-prime because n_1 has no common prime with n_2 and n_1 has no common prime factor with n_3 .

So C_1 which is nothing, but the product of n_2 and n_3 is going to be co-prime with n_1 . Similarly C_2, n_2 are co-prime and C_3, n_3 are co-prime. So once you have these co-prime things then we know that there is a unique solution to this, there is a unique solution to this, there is a unique solution to this modulo each of the n_i . So since $C_i n_i$ is 1 for all i we have a solution k_i to the above congruences and hence k equal to 3 case is done.

So we have done the case k equal to 2 where we had a pair of co-prime integers n_1 and n_2 and then we proved the Chinese remainder theorem for this particular case then we have now the case k equal to 3 where we had three elements, three natural numbers n_1, n_2, n_3 and they had the property that they were relatively pair wise relatively prime or pair wise co-prime and

then we proved that there is a solution to x congruent to $a_1 \pmod{n_1}$, x congruent to $a_2 \pmod{n_2}$ and x congruent to $a_3 \pmod{3}$.

Now the time is to go for a general prove, but we will do it in the next lecture. So, I hope you will remember the cases k equal to 2, k equal to 3 and see you in the next lecture. Thank you.
