Primitive Roots - IV

Welcome back. We are in the middle of the proof actually we are proving that U_n is cyclic whenever n is power of an odd prime. We have proved the case U_p square being cyclic in a separate result and then we started this proof of U_n being cyclic when n is p power e where p is odd and we have just proved that U_p cube is cyclic that was to give you a glimpse of the general proof. I told you that the general proof is by induction and now we have the proof.

(Refer Slide Time: 00:59)

Theorem: If $n = p^e$ then U_n is cyclic.

Proof (contd.): Let $a \in \mathbb{N}$ be primitive in U_{p^2} then a is primitive in U_{p^e} , $e \geq 3$.
 Let us assume the induction hypothesis, that is a is primitive in $U_p, U_{p^2}, U_{p^3}, \dots, U_{p^e}$, and then prove that a is primitive in $U_{p^{e+1}}$.

So, we begin with the assumption that so the assumption is as follows. Let a in \mathbb{N} be primitive in U_p square and we show that a is primitive in U_p cube U_p power e for we proved that it is actually primitive in p power 3, but we will show that it remains primitive in all the higher p power U_p power is. So, let us assume the induction hypothesis that is a is primitive in U_p square, U_p cube so on.

In fact it will remain primitive in U_p also up to p power e and then prove that a is primitive in U_p power e plus 1. This is our plan we will start with the induction as hypothesis that our element remains primitive for all these groups and we will prove that it remains primitive in the next group as well.

(Refer Slide Time: 03:15)

Theorem: If $n = p^e$ then U_n is cyclic.

Proof (contd.): Since a is primitive in $U_{p^{e-1}}$ and U_{p^e} , we get

$$p^{e-1} \mid a^{p^{e-2}(p-1)} - 1, \quad \varphi(p^{e-1}) = p^{e-2}(p-1).$$

$$p^e \mid a^{p^{e-1}(p-1)} - 1, \quad \varphi(p^e) = p^{e-1}(p-1).$$

$$p^e \nmid a^{p^{e-2}(p-1)} - 1, \quad \text{as } a \text{ is primitive in } U_{p^e}.$$

So, since a is primitive in $U_{p^e - 1}$ and U_{p^e} we get the following statements. First of all you will have that $p^e - 1$ will divide $a^{p^e - 2}$ into $p - 1$. Here the Euler phi function of $p^e - 1$ is $1 - p$ into $p - 1$ and similarly we will have that p^e divides $a^{p^e - 1}$ into $p - 1$.

This is because the Euler phi function of p^e is $p^e - 1$ into $p - 1$. Moreover, we have that p^e does not divide the earlier thing as a is primitive in U_{p^e} . These are the three things that we are going to need so we have these three things that p^e divides this quantity $p^e - 1$ we will divide it, but p^e will not divide. You will check that these two are the same $a^{p^e - 2}$ into $p - 1$ and $a^{p^e - 2}$ into $p - 1$.

(Refer Slide Time: 05:25)

Theorem: If $n = p^e$ then U_n is cyclic.

Proof (contd.): The order of a in $U_{p^{e+1}}$ is either

$$\underbrace{p^e(p-1)} \text{ or } \underbrace{p^{e-1}(p-1)} \times, \text{ as } \underbrace{\varphi(p^e)} / \text{order } a / \underbrace{\varphi(p^{e+1})}.$$

Note $a^{p^{e-2}} - 1 = p^{e-1} \alpha \quad (\alpha, p) = 1.$

$$(a^{p^{e-2}})^p = (1 + \alpha p^{e-1})^p$$

Further, when we look at the group U_{p^e} the order of a in U_{p^e} is either p^{e-1} or p^{e-2} as the Euler phi function of p^e should divide the order a and further order a should divide the Euler phi function of p^e . So, we have these possibilities and the difference the ratio of phi of p^e upon phi of p^{e+1} is p .

Therefore, these are the only two possibilities if we show that this is not the order of the element a in $U_{p^{e+1}}$ then we are done then this will have to be the order of a in U_{p^e} . So, for that we go one step back and notice that $a^{p^{e-2}} - 1$ because of what we have observed here is p^{e-1} into some element α which is coprime to p .

This is because the thing on the left-hand side is divisible by p^{e-2} , but not by p^{e-1} . So, therefore we got that one second we have to make a correction here that this 2 is 1. So, we see that this left-hand side is divisible by p^{e-1} , but not by p^e therefore α is coprime to p and now we just raise both sides to the power p . So, we look at $a^{p^{e-2}}$ to the power p . This is $1 + \alpha p^{e-1}$ to the power p and then apply the binomial theorem.

(Refer Slide Time: 08:31)

Theorem: If $n = p^e$ then U_n is cyclic.

Proof (contd.):

$$(1 + \alpha p^{e-1})^p = 1 + \underbrace{p\alpha p^{e-1}}_{p^e \text{ but not by } p^{e+1}} + \underbrace{\sum_{i=2}^p \binom{p}{i} (\alpha p^{e-1})^i}_{p^{e+1}}$$

$a \not\equiv 1 \pmod{p^{e-1}}$

$$\Rightarrow a^{\binom{p-1}{p-1}} \not\equiv 1 \pmod{p^{e+1}}$$

$\Rightarrow o(a) \text{ in } U_{p^{e+1}} \text{ is not } p^{e-1} \binom{p-1}{p-1},$
 hence a is primitive in $U_{p^{e+1}}$. \square

So, $1 + \alpha p^{e-1}$ to the power p will give you $1 + p\alpha p^{e-1}$ plus $1 + \sum_{i=2}^p \binom{p}{i} \alpha^i p^{(e-1)i}$. Now depending on what our p power e is we will see this quite easily that these terms are all divisible by p^{e+1} and moreover on the left hand side we have this to be a power $p^{e-1} \binom{p-1}{p-1}$.

And what we have is that this quantity is divisible by p^e , but not by p^{e+1} . So, it tells us that $a^{\binom{p-1}{p-1}}$ is not congruent to 1 modulo p^{e+1} which is to say that the order of a in $U_{p^{e+1}}$ is not this quantity which is $p^{e-1} \binom{p-1}{p-1}$. Hence a is primitive in $U_{p^{e+1}}$ this completes our long proof which has been going on over several last lectures. So, this proves that when p is in odd prime the group of units modulo n is a cyclic group and the only remaining case now is where n is 2 times p^e .

(Refer Slide Time: 11:07)

Example: $p = 5, a = 2$. $\langle 2 \rangle = U_5$, $\langle 2 \rangle = U_{25}$.

Is 2 primitive modulo 125?

$$2^4 \not\equiv 1 \pmod{25}, 2^{20} \not\equiv 1 \pmod{125}.$$

\Rightarrow order of 2 in U_{125} is 100.

$$\Rightarrow \langle 2 \rangle = U_{125}.$$

But before that let us look at this particular example where we have p equal to 5 and a equal to 2. I hope you will remember that 2 is not just a generator for U_5 , but it is also a generator for U_{25} and now we have to only check or verify that the order of 2 modulo the next prime power next power of 5 which is 125 is correct number or not. So, is 2 primitive modulo 125 this is the question.

So, we observe that 2^4 is not congruent to 1 modulo 25 and this by the proof that we have done we will tell you that 2^{20} is not going to be congruent to 1 modulo 125 and therefore the order of 2 in U_{125} is equal to 100. Remember that the order of 2 in U_{125} could have been 20 or 5 into 20 which is 100 and therefore what we have is that 2 also generates U_{125} .

(Refer Slide Time: 12:40)

Example: $p = 5, a = 7$

$$\langle 7 \rangle = U_5, \quad \langle 7 \rangle \neq U_{25}$$

7 is not primitive in U_{125}

The next example that we had seen in our last lecture was where our a was 7 and we observed that 7 is a generator it is a primitive element for U_5 , but we saw that it is not a primitive element for U_{25} and clearly 7 is not going to be primitive in U_{125} . This is because to have something primitive modulo 125 we should have the element to be primitive modulo 25 to begin with. Now, the only case remaining is U_{2^e} where p is an odd prime and I have promised you that we will show that this group is also a cyclic group.

(Refer Slide Time: 13:37)

Theorem: If $n = 2p^e$ then U_n is cyclic. $p = \text{odd prime}$.

Proof: If p is odd then $\phi(2p^e) = \phi(p^e)$.

$$\text{Let } p=3, e=2, n=18, \frac{n}{2}=9$$

$$U_{18} = \{ \underline{1}, \underline{5}, \underline{7}, 11, 13, 17 \}, \quad \phi(18) = \phi(9) = 6.$$

$$U_9 = \{ \underline{1}, 2, 4, \underline{5}, \underline{7}, 8 \}$$

So, let me remark here again that p remains an odd prime so observe if p is odd then the Euler phi function of 2 times p power e is the Euler phi function of p power e . So, the number of

elements in U_n where n is 2 times p power e is same as the number of elements in $U_{n/2}$, but that does not mean that the numbers are the elements themselves are same because to belong to U_n where n is 2 into p power e each number will have to be an odd number which is not the case when you were looking at U_{p^e} .

So, let me do one basic example where p power e is 3 square which is 9. So, let p be equal to 3 and e be equal to 2 so you have n to be 18 and $n/2$ is 9. Let us observe that U_{18} has elements 1, 2 will not come because 2 is even so we should look at the next odd numbers only 3 will not come, but 5 will come 7 comes, 9 does not come, but 11 and 13 come, 15 does not come, but 17 will come.

So, U_{18} has exactly 6 elements because $\phi(18)$ is $\phi(9)$ which is 6. U_9 has also 6 elements and these are the elements 1, 2, 4, 5 and 7, 8. So, note that for every even element here there is an element which is just obtained by adding 1 times 9 to it to get the next element. So, 8 plus 9 is actually 17 and this is how we get this number. So, 1, 5 and 7 these are the elements which remained as they were. And for all the even elements in U_9 we simply had to add 9 once to get the next element. So, this is how we see that the orders of these two groups are same and in fact we will prove that both the groups are actually isomorphic.

(Refer Slide Time: 16:54)

Theorem: If $n = 2p^e$ then U_n is cyclic.

Proof (contd.): Let $a \in \mathbb{N}$ be a primitive root

in U_{p^e} . Then $p^e \mid a^{\phi(p^e)} - 1$. If a is odd

then $a^{\phi(p^e)} - 1$ is even, so $2 \mid a^{\phi(p^e)} - 1$, $(2, p^e) = 1$.

So $2p^e \mid a^{\phi(p^e)} - 1$. Then a is primitive

in U_{2p^e} .

So, the proof would be as follows let a in \mathbb{N} be a primitive root in U_{p^e} because whenever we have a divisor of n which is 2 times p power e and we are looking for primitive roots modulo n it should remain a primitive root modulo U_{p^e} as well. So, what it says

is that p power e is going to divide the element a raise to the correct order which is ϕ of p power e minus 1.

Now, if a is an odd number then a raise to p power e minus 1 is even so 2 divides this quantity. You have that 2 divides one particular number you have that p power e also divides the same number and 2, p power e these are coprime because p is odd. So, 2 times p power e will have to divide this number a to the power ϕ p power e minus 1 and then we are done because then a is primitive in U 2 times p power e as well.

So, the only situation where we will not get a to be a primitive root would be when a is not odd if a is even then this number that we get here will not be even this will actually be odd and you will not have to dividing a raise to ϕ p power e minus 1.

(Refer Slide Time: 19:26)

Theorem: If $n = 2p^e$ then U_n is cyclic.

Proof (contd.): If a is even then let

$$b = a + p^e. \text{ Here } b \in U_{2p^e} \text{ and}$$

$b \equiv a \pmod{p^e}$. All the earlier discussion now gives us that b is primitive in U_{2p^e} .

So, if a is even then we have to get a separate proof then let b be a plus p power e . Here b is an element in U 2 times p power e and b is congruent to a mod p power e . So, all the earlier discussion now holds for b a is even and you have added an odd prime power to it so b is odd. So, all the earlier discussion now gives us that b is primitive in U 2 times p power e and so whenever n is 2 times power of an odd prime then U_n is a cyclic group. So, we have computed all U_n which are cyclic groups.

(Refer Slide Time: 21:05)

We have thus found all U_n which are cyclic.

$$n = 2, 4$$

$$n = p^e \quad p \text{ odd prime}$$

$$n = 2p^e \quad p \text{ odd prime.}$$

And just to recall this for you these are where n is 2, n is 4, n is power of an odd prime or n is 2 times p power e where p is an odd prime. These are all the cases where our groups U_n are cyclic and in all the remaining cases we have seen that the groups U_n cannot be cyclic. So, as far as getting the cyclic group structure on U_n is concerned we have solved the problem. However we cannot say that we have understood all U_n . Because we do not understand the structure of the other U_n which are not yet cyclic. So that is something that we would want to do.

(Refer Slide Time: 22:03)

We have thus found all U_n which are cyclic.

We are yet to determine the structure of the remaining U_n .

We start by analysing the structures of U_n where n

is 2^e . $2^e = 8$, U_2, U_4 being cyclic; $U_8 \cong C_2 \times C_2$,
 $2^e = 16$, $U_{16} = \{1, 3, 5, 7, 9, 11, 13, 15\} = \{\pm 5, \pm 5^2, \pm 5^3, \pm 5^4\}$
 $C_2 \times C_4$. $\langle 5 \rangle = \{5, 5^2 = 9, 5^3 = 13, 5^4 = 1\} = \{5, 9, 13, 1\}$

We are yet to determine the structure of the remaining U_n which are not cyclic if you remember these were the n for which n had two or more prime factors or n was of the form 4 into m where m is odd or it was of the form 8 into anything. So, 8 divided n or 4 divided n and the factor is an odd element bigger than 1 of course and the other third possibility was that n is product of two or more distinct prime powers.

So, it has two or more distinct prime factors. These were the cases where the groups U_n are not cyclic and we want to understand the structure of these groups. So, once again we will begin by looking at the groups of the form U_n where n is a power of 2 . The very basic such case would be where we would look at U_8 . So, we consider the case 2 power e equal to 8 . If you remember U_2 and U_4 are already cyclic and we also saw that U_8 is isomorphic to C_2 cross C_2 .

So, the next case we should look at is 16 U_{16} has 8 elements all the elements which are odd numbers up to 16 and here I will give you one particular subgroup. The subgroup generated by 5 is 5 square which is 9 modulo 16 5 cube is 45 and so modulo 16 this is 13 and then 5 raise to 4 which is 13 into 5 which is 65 so that is 1 modulo 16 . So, we get this group to be $5, 9, 13$ and 1 and we observe that this therefore is plus minus 5 .

Because we have these elements so $5, 9, 13$ and 1 these are already there and their negatives are these elements. So, negative 5 is 11 negative 9 is 7 , negative 13 is 3 and negative 1 is 15 . So, we get that our group is actually plus minus 5 plus minus 5 square plus minus 5 cube and plus minus 5 raise to 4 . Thus, U_{16} is C_2 cross C_4 . So, the structure of the group U_{2^e}

where 2^e is 8 or above is that it will have a direct factor which is C_2 in both these cases 8 as well as 16 we got a direct factor which is C_2 .

And then there is one more cyclic subgroup which together with C_2 gives us the U_{2^e} completely. So, this is the way we are going to prove our result finally that the group U_n where n is 2^e bigger than or equal to 8 then U_n is product of two cyclic groups. One of them being of order 2. So, I hope to see you in the next lecture to study this. Thank you.
