Lecture – 24

Second Order Partial Differential Equations Characteristics Surfaces

So, in our discussion on the second order partial differential equations, so far we have considered partial differential equations second order in two independent variables. In this lecture on the next we are going to discuss second order partial differential equations in more than two independent variables. The first concept that we are going to discuss is what is called characteristic surfaces. These are generalization of characteristic curves that we have seen in the discussion of second order equations in two independent variables.

(Refer Slide Time: 00:50)

The outline for today's lecture is, we first recall the characteristic surfaces and classification which was done in two dimensions which is same as in two independent variables, whatever we have covered for the partial differential equations. Where we call it was a characteristic curves and we have of course, classified based on characteristic curves. So, we will recall that and then we generalize that to higher dimensions.

And they are now called characteristic surfaces for obvious reasons, because they are going to be one dimensionless. For example, characteristic curve, it is a curve in \mathbb{R}^2 . Now here we will

have to imagine things which are just one dimensionless. So, that is why we will come to that, then we will understand what this means. And then we classify the linear equations in more than two variables.

(Refer Slide Time: 01:38)

Linear PDE in d -dimensions

$$\sum_{i,j=1}^d a_{ij}(x) \frac{\partial^2 u}{\partial x_i \partial x_j} + \sum_{i=1}^d b_i(x) \frac{\partial u}{\partial x_i} + c(x)u + d(x) = 0 \quad (d-L)$$

where

- a_{ij}, b_i, c, d are functions defined on a domain in \mathbb{R}^d .
- $a_{ij} = a_{ji}$ for every i, j .
- x denotes $\mathbf{x} = (x_1, x_2, \dots, x_d)$.

So, linear PDE in d dimensions, this how we call it is an equation of this form. There is a most general linear partial differential equation in d independent variables. Often, we call that d dimensions PDE in d dimensions means, there are d independent variables. $\sum_{ij=1}^d a_{ij}$ of x $\frac{\partial^2 u}{\partial x_i \partial x_j}$. This is often called what called a principal part of the PDE. So, it is that part of the PDE where the highest order derivative appears.

The highest order derivative appears with power one, coefficients may depend on x u and first order derivatives, does not matter. So, this is what is called principal part. In the context of this d dimensional linear equation, the principal part is precisely this, because this is where the second order partial derivatives of u appear. If you recall in the case when d could do the classification and characterization of characteristic curves is actually based on the principal part.

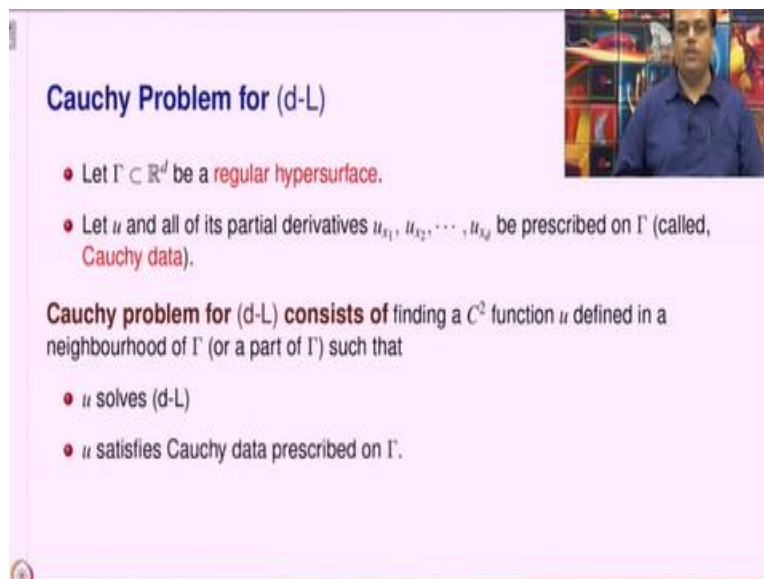

So, similarly, it is going to play a role even in higher dimensions. That is why I have introduced the word formerly, that word is a principal part of a linear partial differential equation. It is that part where the highest order partial derivatives appear. And some people call this one as a lower order term sometimes, because it involves derivatives of u not of second order but of

orders less than 2 that is 1 or no derivative.

We have to make some place assumptions on the equations without which we cannot do the theory. So, we are going to assume that a_{ij} , b_i , c , d , of course, they are functions of x defined on a domain that is x belongs to some domain \mathbb{R}^d , we also assume that these are continuous functions for simplicity. We most importantly assume that $a_{ij} = a_{ji}$ because a_{ij} is a coefficient of $\frac{\partial^2 u}{\partial x_i \partial x_j}$, a_{ji} is a coefficient of $\frac{\partial^2 u}{\partial x_j \partial x_i}$.

And if you are expecting twice continuously differentiable function as a solution to this equation, then $\frac{\partial^2 u}{\partial x_i \partial x_j}$ is same as $\frac{\partial^2 u}{\partial x_j \partial x_i}$. The order in which you take the second order partial derivative does not matter. Therefore, we can always make this to be symmetric a_{ij} equal to a_{ji} . So, this is a condition that we must place, so let us assume this. And this x which is in the boldface actually stands for x_1, x_2, \dots, x_d in \mathbb{R}^d .

(Refer Slide Time: 04:35)

Cauchy Problem for (d-L)

- Let $\Gamma \subset \mathbb{R}^d$ be a **regular hypersurface**.
- Let u and all of its partial derivatives $u_{x_1}, u_{x_2}, \dots, u_{x_d}$ be prescribed on Γ (called, **Cauchy data**).

Cauchy problem for (d-L) consists of finding a C^2 function u defined in a neighbourhood of Γ (or a part of Γ) such that

- u solves (d-L)
- u satisfies Cauchy data prescribed on Γ .

So, what is the Cauchy problem for the equation d-L? That is d-dimensional linear equation, this is a shortcut form of calling d-dimensional linear equation, we just call d-L. So, what is the Cauchy problem? Take Γ subset of \mathbb{R}^d , which is a regular hypersurface. Let u and on all of its partial derivatives namely u_{x_1}, u_{x_2} up to u_{x_d} be described on Γ . This is often called Cauchy data.

Cauchy problem for d-L consists of finding a C^2 function defined in a neighbourhood of Γ . Because the x where the function u and the partial derivatives are prescribed or even a part of Γ . Now, we are used to this idea that Cauchy problem need not have solution defined around entire Γ ; it could be a part of Γ . Such that u solves d-L, it should be a solution of the partial differential equation and the given Cauchy data should be satisfied by u .

(Refer Slide Time: 05:44)

Remark on Cauchy Problem for (d-L)

What is the meaning of $\Gamma \subset \mathbb{R}^d$ is a regular hypersurface?

- When $d = 2$, how did we define a Γ is a regular curve?
 - We considered Γ which is a parametrized curve.
 - Regularity meant that at every point of Γ , there is a well-defined tangent.
 - Equivalently, a well-defined normal exists at every point of Γ .
- Even in higher dimensions, Γ may be taken as a parametrized surface, parametrized by $d - 1$ parameters.
 - Regularity means that at each point of Γ , a well-defined tangent plane exists.
 - Equivalently, a well-defined normal exists at every point of Γ .

We will come back to this discussion

Now, what is the meaning of $\Gamma \subset \mathbb{R}^d$ is a regular hypersurface? There are two words regular and hypersurface. Normally, hypersurface means somebody who just one dimensionless in the whole space. For example, in \mathbb{R}^3 a plane would be a hypersurface, two dimensional planes or a sphere that would be hypersurface. Because a sphere; can be described using two parameters whereas in \mathbb{R}^3 , we need kind of three parameters.

So, that is the meaning of the hypersurface and what is regular? It is something about smoothness, we will see that. So, when d equal 2, how did we define Γ is a regular curve? First of all, we can start Γ which is a parameter is curved to start with and regularity meant that at every point of Γ , there is a well-defined tangent. Equivalently, it means that a well-defined normal exists at every point of Γ .

Even in higher dimensions Γ may be taken as a parameterized surface, parameterized by

$d - 1$ parameters. When $d = 2$, the curve prescribed by one parameter when you are in \mathbb{R}^d it will be prescribed by $d - 1$ parameters, so parameterized by $d - 1$ parameters. Regularity means that at each point of γ in the case of $d = 2$ we said well-defined tangent, now, that becomes well defined tangent plane exists.

Therefore, equivalently a well-defined normal exists at every point of γ . We will come back to this discussion towards the end of this lecture.

(Refer Slide Time: 07:26)

Remark on Cauchy Problem for (d-L) (contd.)

- When $d = 2$, the function u and only its normal derivative were prescribed.
 - But we found that it is equivalent to prescribing u and all its partial derivatives.
- Even in higher dimensions, one may prescribe the function u and its normal derivative on Γ . In such a case,
 - All tangential derivatives are completely determined on Γ since u is prescribed. They are $d - 1$ in number.
 - Normal derivative is also prescribed.
 - Thus a total of d directional derivatives are determined along Γ .
 - Since Γ is a regular hypersurface, prescribing any d directional derivatives (in independent directions) is equivalent to prescribing the d partial derivatives

When $d = 2$ the function u and only as normal derivative were prescribed, like recall lecture 3.1. But we found that it is equivalent, what is the equivalent? Prescribing functions u and only its normal derivative. This is equivalent to prescribing u on all its partial derivatives. Why is it so? Because the; γ was a regular curve. We can determine all derivatives if we knew the function and the normal derivative.

So, even in higher dimensions one may prescribe the function u and its normal derivative on γ , it can be done. In such a case what do you have? All tangential derivatives are completely determined on γ , why is that? Because the function is given on γ and they are $d - 1$ in number. Normal derivative is also prescribed. For example, imagine your γ is let us say in $d=3$ γ is xy plane.

So, you are prescribing u on xy plane, it means automatically u_x and u_y are determined on xy plane. So, these are the tangential derivatives which are obviously $d-1$ in number that is 2 in number, u_x and u_y . Normal derivative is nothing but u_z . So, if you give u_z , you have three derivatives. Now, same thing is true even if γ is not xy plane, γ is a regular hypersurface.

So, even in case of regular hypersurface you are given u on γ , therefore, all tangential derivatives can be determined. Keep in mind the example of the xy plane has γ and \mathbb{R}^d is \mathbb{R}^3 . Normal derivatives also prescribed, thus a total of d directional derivatives are determined along γ , $d-1$ is here and one more here therefore, $d-1+1$ that is d . So, you have d directional derivatives and the important thing is directions are independent derivatives.

Since γ is a regular surface, prescribing any d directional derivatives in independent directions is equivalent to prescribing all the d partial derivatives u_{x_1}, u_{x_2} up to u_{x_d} .

(Refer Slide Time: 09:48)

So, let us review characteristic surfaces and classification as was done in the case of two independent variables.

(Refer Slide Time: 09:57)

Recall from Lecture 3.1

The following linear system appeared in the computation of second order derivatives from the PDE and the Cauchy data

$$\begin{pmatrix} f'(s) & g'(s) & 0 \\ 0 & f'(s) & g'(s) \\ a(\zeta(s)) & 2b(\zeta(s)) & c(\zeta(s)) \end{pmatrix} \begin{pmatrix} u_{xx}(f(s), g(s)) \\ u_{xy}(f(s), g(s)) \\ u_{yy}(f(s), g(s)) \end{pmatrix} = \begin{pmatrix} p'(s) \\ q'(s) \\ -d(\zeta(s)) \end{pmatrix}$$

$$A x = b, \det A = 0$$

Determinant of the matrix (denoted by $\Delta(s)$) has the following expression

$$\Delta(s) := c(\zeta(s)) (f'(s))^2 - 2b(\zeta(s)) f'(s) g'(s) + a(\zeta(s)) (g'(s))^2$$

If $\Delta(s) = 0$, then what are the implications?

So, let us recall from lecture 3.1. We had a linear system when we are trying to compute the second order derivatives from the PDE and the Cauchy data alone. So, this is the system, f and g was the parameterization of the gamma, gamma is fs , $x = fs$, $y = gs$. So, we are trying to determine the second order derivatives, then it satisfies system of linear equations non homogeneous. Determinant of this matrix was what is called delta of s , this is the determinant.

If you expand this determinant, you will get this formula; we did this in lecture 3.1. Now, if $\Delta(s) = 0$ then what are the implications, what will happen? So, in other words you have a system let us call this $A x = b$, we have a system $A x = b$ and determinant of $A = 0$. What can you say about the solutions of this system $A x = b$? What we can say is there will be b for which there is no solution, there will be for which there will be solution.

But the moment you have one solution you have infinitely many solutions. So, you will never have a unique solution either you have no solution or infinitely many solutions.

(Refer Slide Time: 11:33)

If $\Delta(s) = 0$, then the system

$$\begin{pmatrix} f'(s) & g'(s) & 0 \\ 0 & f'(s) & g'(s) \\ a(\zeta(s)) & 2b(\zeta(s)) & c(\zeta(s)) \end{pmatrix} \begin{pmatrix} u_{xx}(f(s), g(s)) \\ u_{xy}(f(s), g(s)) \\ u_{yy}(f(s), g(s)) \end{pmatrix} = \begin{pmatrix} p'(s) \\ q'(s) \\ -d(\zeta(s)) \end{pmatrix}$$

- Can have **NO solutions**. This happens when PDE and Cauchy data are incompatible.
- Can have **infinite number of solutions**. This happens when PDE and Cauchy data are compatible.

The next example illustrates these possibilities.

So, if $\Delta s = 0$, then this system can have no solutions. When will that happen? When the data is incompatible with a PDE. It can have infinite number of solutions; this will happen when you have compatibility between the PDE and the Cauchy data. The next example illustrates these possibilities very clearly; it is a very simple partial differential equation.

(Refer Slide Time: 12:03)

Example

Consider the Cauchy problem

$$u_{xy} = 0,$$

$$u(x, 0) = f(x), u_y(x, 0) = g(x), x \in \mathbb{R}.$$

- The general solution of the PDE is given by $u(x, y) = F(x) + G(y)$.
- This u satisfies the Cauchy data **if and only if** the following equalities hold:

$$F(x) + G(0) = f(x)$$

So, the Cauchy problem is $u_{xy} = 0$ and $u(x, 0)$ is given to be $f(x)$, $u_y(x, 0)$ is given to be $g(x)$, that is u is prescribed. And the normal derivative is prescribed on x axis, here γ is x axis. What about this problem? The general solution of the PDE, $u_{xy} = 0$ is given by a function of x plus function of y . Because you integrate this, $u_{xy} = 0$, imagine it is d by dy of $u_x = 0$, then u_x becomes a function of x and you integrate you get this is a function of x plus function of y .

This u satisfies the Cauchy data. What is the Cauchy data? These are the equations. So, when is $u(x, 0) = f(x)$, substitute here, put $y = 0$, you get $f(x) + G(0)$ must be equal to $f(x)$, this is the first condition. What about the second condition? You need to differentiate u with respect to y that will give you a $G'(y)$ and when $y = 0$, then $G'(0)$ that will give you $g(x)$. So, these are the two conditions that we get.

(Refer Slide Time: 13:26)

Example (contd.)

- If the equalities

$$F(x) + G(0) = f(x), \quad G'(0) = g(x)$$
 hold, then the function g **MUST** be constant.
 - If g is not a constant function, the given **Cauchy problem does not have a solution.**
 - If g is a constant function, the Cauchy problem admits **infinitely many solutions.** Proving this assertion is left as an exercise.

So, if these equations hold, then the function g must be constant, because $G'(0)$ is a number that means g is a number. If g is not a constant function, then the Cauchy problem does not have a solution that is very clear from this, this is not satisfied. If g is a constant function, then Cauchy problem admits infinitely many solutions. Just convince yourself, it is a very simple to show that you can have infinitely many solutions. Proving this assertion is left as an exercise for you, very simple.

(Refer Slide Time: 14:07)

Example (contd.)

- Note that Cauchy data was prescribed on the line $y = 0$ which is a characteristic curve for the given PDE.

- For,

$$\Delta(s) := c(f(s), g(s)) (f'(s))^2 - 2b(f(s), g(s)) f'(s) g'(s) + a(f(s), g(s)) (g'(s))^2.$$

- In the present case $a = c = 0$ and $f(s) = s, g(s) = 0$. Thus $\Delta(s) = 0$.
- Note that u_{yy} cannot be determined along $y = 0$ using the equation and the Cauchy data

Now, observe that the Cauchy data is prescribed on the line $y = 0$. That is the x axis which is a characteristic curve for the given PDE. Let us check that. $\Delta(s)$, this is a formula $c f' \text{ prime square} - 2b f' \text{ prime } g' \text{ prime} + a g' f' \text{ prime } g' \text{ prime squared}$. What is a, b, c in our case? a and c are 0, our equation was $u_x y = 0$. So, a and c are 0 and γ is x axis, therefore f is s and g is 0. When we plug in this into this what we get is $\Delta(s)$ is 0.

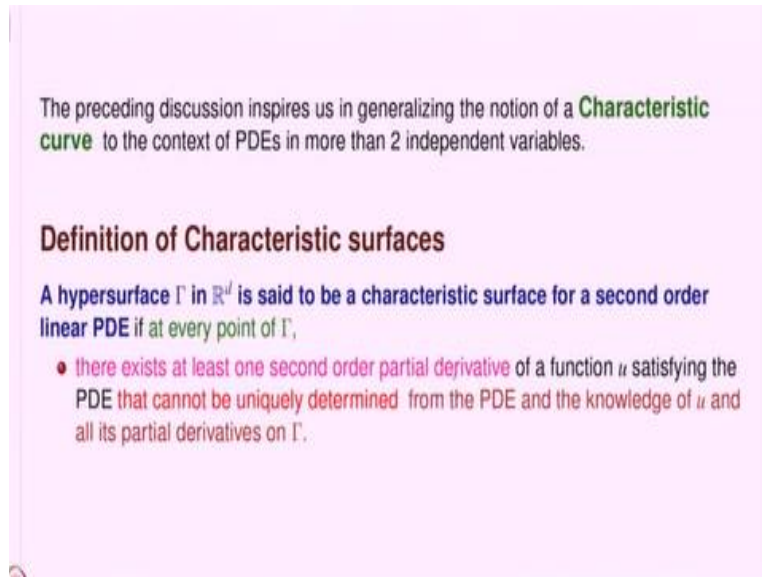

So, it is a characteristic curve and clearly u_{yy} cannot be determined along the x axis. Using the equation and the Cauchy data because Cauchy data gives you only u_x and u_y anyway is given, but u_{yy} you cannot get because it is not there in the equation.

(Refer Slide Time: 15:03)

Characteristic surfaces in higher dimensions

So, now we are ready to define what are characteristic surfaces in higher dimensions.

(Refer Slide Time: 15:10)

The preceding discussion inspires us in generalizing the notion of a **Characteristic curve** to the context of PDEs in more than 2 independent variables.

Definition of Characteristic surfaces

A hypersurface Γ in \mathbb{R}^d is said to be a characteristic surface for a second order linear PDE if at every point of Γ ,

- there exists at least one second order partial derivative of a function u satisfying the PDE that cannot be uniquely determined from the PDE and the knowledge of u and all its partial derivatives on Γ .

So, the preceding discussion inspires us in generalizing the notion of a characteristic curve to the context of PDFs in more than 2 independent variables. So, let us define the notion of characteristic surfaces, what is that? A hypersurface in \mathbb{R}^d is said to be a characteristic surface for a second order linear PDE. If at every point of gamma, there exists at least one second order partial derivative of a function u , which satisfies the PDE.

And that cannot be uniquely determined from the PDE on the Cauchy data. That is from the PDE and the values of u and all its partial derivatives alone come. From this knowledge of u and all its partial derivatives on gamma you cannot determine at least one second order partial derivative, uniquely determined, cannot be uniquely determined means either you have too many values or no values.

(Refer Slide Time: 16:22)

Let $\Gamma \subset \mathbb{R}^d$ be a hypersurface.

Γ is said to be a **non-characteristic hypersurface** for a second order linear PDE if at every point of Γ ,

- all the second order partial derivatives of a solution to the PDE are uniquely determined from the PDE and the knowledge of u and all its partial derivatives along Γ .

Understand the difference between

- " Γ is NOT a characteristic hypersurface" and
- " Γ is a non-characteristic hypersurface" as defined above.

Hint. Understand the difference between $\Delta(s) \equiv 0$ on I and $\Delta(s) \neq 0$ for all $s \in I$.
One is **NOT** a negation of the other!

That is no solution or infinitely many solutions. If you recall that is what is a true within two dimensions, when $\Delta s = 0$ we have the two possibilities which are seen in the last example. So, let Γ be hypersurface, now, we are going to define a non characteristic hypersurface. Γ is said to be a non characteristic hypersurface recall what we are defined in the previous slide, what is a characteristic surface?

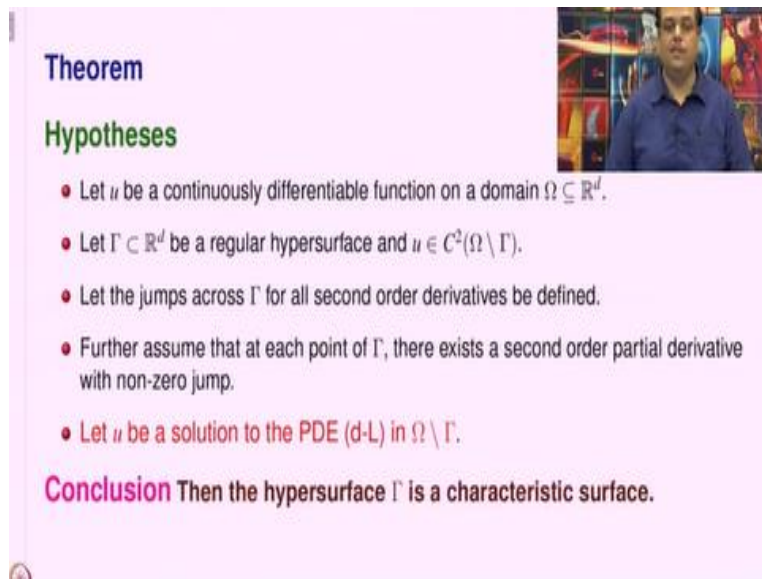

Now, we are defining what is called non characteristic hypersurface. What is that? At every point of Γ , all the second order partial derivatives of a solution to the PDE can be determined uniquely from the PDE and the knowledge of u along the Γ and partial derivatives of u along the Γ . Now, I would like you to think about the following; understand the difference between Γ is not a characteristic hypersurface.

On the previous slide we define what is the meaning of Γ is a characteristic hypersurface. Therefore, Γ is not a characteristic hypersurface and Γ is a non characteristic hypersurface, there is a difference. I just give you a hint understand the difference between Δs identically equal to 0 on I , in fact these we call a characteristic curve if this happens. And Δs is never 0, that means that curve was non characteristic curve that is a difference.

One is not a negation of the other. You may call one is the extreme negation of other, that is fine. But you must understand the difference between not a characteristic hypersurface and non

characteristic hypersurface, both are different.

(Refer Slide Time: 18:17)

Theorem

Hypotheses

- Let u be a continuously differentiable function on a domain $\Omega \subseteq \mathbb{R}^d$.
- Let $\Gamma \subset \mathbb{R}^d$ be a regular hypersurface and $u \in C^2(\Omega \setminus \Gamma)$.
- Let the jumps across Γ for all second order derivatives be defined.
- Further assume that at each point of Γ , there exists a second order partial derivative with non-zero jump.
- Let u be a solution to the PDE (d-L) in $\Omega \setminus \Gamma$.

Conclusion Then the hypersurface Γ is a characteristic surface.

We have a theorem, let u be a C^1 function on a domain Ω in \mathbb{R}^d , let Γ be a regular hypersurface and $u \in C^2$ on $\Omega \setminus \Gamma$ that means, what we are thinking of is a situation like this you have an Ω and you have a Γ . Then $u \in C^2$ here at all these points. But $u \in C^1$ throughout and jumps across Γ for all secondary derivatives are defined, that means that at points here at points on Γ , look at any derivative that you think of $u_{x_1 x_2}$ this is one partial derivative.

This jump is defined, that means $u_{x_1 x_2}$ coming from this domain let us call it Ω_1 , call this Ω_2 , a point here the $u_{x_1 x_2}$ the second derivative has a meaning. That means it is continuous from this side. So, that means in other words u restricted to Ω_1 is actually a continuous function of up to closure. So, that the values of second order partial derivatives make sense on Γ . Similarly, u restricted to Ω_2 is C^2 of Ω_2 , not C^2 in fact C^2 .

Because we already assumed $u \in C^1$, there is no need of writing C^2 of Ω_1 , Ω_2 , what we want actually is about second order derivatives have values at points of Γ coming from the right-hand side or left-hand side. I have written a picture in \mathbb{R}^2 , that is why I am using the word right hand side of things. So, in other words, what I am assuming is that this hypersurface Γ cuts Ω into two parts.

One part you call it ω_1 , another part you call ω_2 , $u \in C^1$ on the whole domain ω , but on each part, u is C^2 of ω_i when you restricted to ω_i . So, that jumps these are well defined quantities. So, now I am going to talk about that in the next hypothesis. Assume that at each point of Γ , some second order partial derivative has a non 0 jump and let u be a solution to the PDE in both the parts ω_1 and ω_2 as I have written down.

Then conclusion is about Γ , Γ must be a high characteristic surface, the hypersurface Γ must be a characteristic hypersurface. Sometimes I am calling characteristic surface, sometimes I am calling characters hypersurface does not matter, because anyway, Γ is a hypersurface to start with. So, it is a characteristic surface.

(Refer Slide Time: 21:18)

Proof of Theorem

- If Γ is not a characteristic surface, then there is a point of Γ , say P , at which all second order partial derivatives of u can be uniquely determined from the PDE and the knowledge of u and all its partial derivatives along Γ .
- Expression for them involves u and its partial derivatives along Γ apart from the functions a_{ij}, b_i, c, d .
- We assumed that $u \in C^1(\Omega)$, and a_{ij}, b_i, c, d are continuous.
- Thus, at P , we get the same values for all second order derivatives on Γ , and hence have no jumps across Γ .
- Thus all the second order partial derivatives of u are continuous across Γ .
- From here, we conclude that Γ is a characteristic surface. \square

Suppose it is not a characteristic surface, so, the proof is going to be like this, I assume that the conclusion does not hold, and I will show that one of them does not happen. In fact, I am going to show this does not happen, all secondary derivatives are continuous across Γ . I am going to show that, so that we prove this here. So, assume Γ is not a characteristic surface. Then there is a point of Γ at which all second order partial derivatives are determined uniquely called a point P .

There is at least one point so call that point P . All the second order partial derivatives can be

uniquely determined from the PDE and the knowledge of u and all its partial derivatives along γ , this is always there. From this, this is what we call Cauchy data in the Cauchy problem. From there and the PDE, we can determine all second order partial derivatives uniquely at that point. Now, this is where you should compare with what we did in lecture 3.1.

Expression for them involves exponent for what? Exponent for the second order partial derivatives involves u and its partial derivatives along γ apart from the coefficient functions in the PDE a_{ij} , b_i , c and d , we assumed $u \in C^1$ of Ω and the a_{ij} , b_i , c , d are continuous. Therefore, at P we get the same values for all second order partial derivatives on γ , whether you come from the Ω_1 side or Ω_2 side, you have the same value.

That means no jump across γ . Thus, all second order partial derivatives are continuous across γ and as we discussed at the beginning of the proof, this finishes the proof of the theorem.

(Refer Slide Time: 23:11)

How to identify Characteristic surfaces?

- In order to identify characteristic surfaces for PDEs, it is useful to find quantitative criteria.
- The Example (which we discussed at the beginning of this Lecture) suggests:
 - If $\frac{\partial^2 u}{\partial x_k^2}$ does not feature in the equation, then $x_k = 0$ would be a characteristic surface.

This discussion gives rise to a necessary and sufficient condition for a regular hypersurface

$$\Gamma : \varphi(x) = 0$$

to be a characteristic surface.

How to identify characteristics surfaces? These are next question because what we have defined characteristic surface is a quality to definition. It just says that some partial second order partial derivative is not uniquely determined at each point of γ , such a γ was called characteristic surface, this is a qualitative definition. Now, we would like to have a quantitative

version of this. So, that we can go and find some characteristics surfaces.

So, therefore, it is useful to find quantitative criteria. The example which we discussed at the beginning of the lecture suggests the following. If $\frac{\partial^2 u}{\partial x^k} = 0$ does not feature in the equation, then $x^k = 0$ would be a characteristic surface. In that example, what was the example? It was $u_{xx} = 0$ and we have looked at $u_{x,0}$ is given to the f and $u_{y,x,0}$ is a normal derivative given to be g .

And we could not get what is u_{yy} using this PDE and the Cauchy data u_{yy} was missing. So, if some derivative is missing, then that variable equal to 0 will be a characteristic surface this idea. So, this discussion gives rise to a necessary and sufficient condition for a regular hypersurface. Now, we are going to look at hyper surfaces of this form $\phi(x) = 0$ to be a characteristic surface. This mean set of all x in \mathbb{R}^d such that $\phi(x) = 0$.

So, called level set of the function ϕ , we are going to derive an excellent sufficient condition for regular hypersurface of this form to be a characteristic surface.

(Refer Slide Time: 25:09)

Lemma: Necessary and Sufficient condition for a Characteristic surface

Let Γ be a **regular hypersurface** defined as the level set of a smooth function $\varphi_1 : \mathbb{R}^d \rightarrow \mathbb{R}$:

$$\Gamma = \{x \in \mathbb{R}^d : \varphi_1(x) = 0\},$$

and such that $\nabla \varphi_1(x) \neq 0$ for each $x \in \Gamma$.

The following statements are equivalent.

- 1. Γ is a characteristic surface for the linear PDE (d-L).
- 2. φ_1 satisfies

$$\nabla \varphi_1 \cdot (A \nabla \varphi_1) = 0, \quad (\text{Eqn. Chara. Surface})$$

where A is the matrix $A = (a_{ij})$.

So, let γ be a regular hypersurface defined as the level set of a smooth function ϕ_1 from \mathbb{R}^d to \mathbb{R} , what is the definition? Set of all x in \mathbb{R}^d such that $\phi_1(x) = 0$ and gradient of ϕ_1 is not 0 for each x in γ . So, this actually tells you that there is a clearly defined

normal at every point of γ . So, this is the regularity hypothesis for the hypersurface. Then the following statements are equivalent, what are those?

Γ is a characteristic surface for $d-L$, that is same as saying that this ϕ_1 Γ is defined through the function ϕ_1 that ϕ_1 satisfies this PDE. What is the PDE? $\text{grad } \phi_1 \cdot A \text{ of } x \text{ grad } \phi_1 = 0$. What is A ? A is the matrix a_{ij} which is appearing in the principal part of the equation $d-L$. So, these are the equation for characteristic surface, a level set $\phi_1(x) = 0$ is a characteristic hypersurface if and only if this equation is satisfied. Of course, this is a first order PDE nonlinear.

(Refer Slide Time: 26:28)

Proof of Lemma

- Consider a nonsingular coordinate transformation given by

$$(x_1, x_2, \dots, x_d) \mapsto (\eta_1, \eta_2, \dots, \eta_d),$$
 where $\eta_i = \varphi_i(x)$ for $i = 1, 2, \dots, d$. Existence is an exercise in Analysis.
- Under change of coordinates, we have a function $w := w(\eta_1, \eta_2, \dots, \eta_d)$ such that

$$u(x_1, x_2, \dots, x_d) = w(\varphi_1(x), \varphi_2(x), \dots, \varphi_d(x))$$

So, consider a nonsingular coordinate transformation given by x_1, x_2, x_3 going to η_1, η_2 to η_d and η_i equal to ϕ_i of x . We are given only ϕ_1 of x , therefore η_1 is $\phi_1(x)$, now you find ϕ_2 of x, ϕ_3 of x, ϕ_d of x so that we have this coordinate transformation defined which is very easy. So, it can always be done, that is an exercise in analysis. Essentially what we are asking is can you given a function ϕ_1 with $\text{grad } \phi_1 \neq 0$.

Can you find ϕ_2, ϕ_3 up to ϕ_d is as a certain Jacobian is non 0? That is the question is possible. Now under the change of coordinates, we have a new function w related to u, w of η_1, η_2, η_d such that u at the point x is equal to w at $\phi_1(x), \phi_2(x)$ and $\phi_d(x)$.

(Refer Slide Time: 27:24)

Proof of Lemma (contd.)

- The given PDE (d-L) will be transformed into the new coordinate system.
- We then find conditions under which the partial derivative $\frac{\partial^2 w}{\partial \eta_1^2}$ does not appear in the transformed equation.
- We know that disappearance of $\frac{\partial^2 w}{\partial \eta_1^2}$ is a sufficient condition for Γ to be a characteristic surface.
- **Question.** Is it also a necessary condition for Γ to be a characteristic surface?

Now, the given PDE will be transformed into the new coordinate system and then we find conditions under which $\frac{\partial^2 w}{\partial \eta_1^2}$ does not appear. Remember $\eta_1 = 0$ is same as set of all x as at $\phi_1(x) = 0$ is a hypersurface and that is precisely our Γ . So, we know that disappearance of this is a sufficient condition for Γ to be a characteristic surface. So, we asked the question, is it also a necessary condition?

(Refer Slide Time: 27:55)

Proof of Lemma (contd.)

Question. Is disappearance of $\frac{\partial^2 w}{\partial \eta_1^2}$ also a necessary condition for Γ to be a characteristic surface?

- When Cauchy data is prescribed on Γ , which in the new coordinate system is $\eta_1 = 0$, we will not be able to determine the derivative $\frac{\partial^2 w}{\partial \eta_1^2}$ from the PDE and Cauchy data.
- As a consequence, one of the second order partial derivatives $\frac{\partial^2 u}{\partial x_i \partial x_j}$ cannot be determined along Γ . Why? **Hint.** Think of Chain rule.

Answer is yes. When Cauchy data is prescribed on Γ , which in the new coordinate system is $\eta_1 = 0$, we will not be able to determine this derivative, $\frac{\partial^2 w}{\partial \eta_1^2}$ for the PDE and the Cauchy data. As a consequence, one of the second order partial derivatives $\frac{\partial^2 u}{\partial x_i \partial x_j}$ cannot be determined along Γ uniquely. Why? Because there;

should be some connection between these derivatives this derivative and these derivatives.

Imagine you can find out all of them, and then can I write this as a combination of that? Think about this. Think about Chain rule.

(Refer Slide Time: 28:38)

Proof of Lemma (contd.)

- Since the term $\frac{\partial^2 w}{\partial \eta_1^2}$ would arise only from the *principal part* of the given PDE, namely

$$\sum_{i,j=1}^d a_{ij}(\mathbf{x}) \frac{\partial^2 u}{\partial x_i \partial x_j}, \quad (\text{Principal Part})$$

we will find an expression for **(Principal Part)** in the new coordinate system.

- Indeed, **(Principal Part)** gives rise to

$$\sum_{i,j=1}^d A_{ij} \frac{\partial^2 w}{\partial \eta_i \partial \eta_j}, \quad \text{where } A_{ij} = \sum_{k,l=1}^d a_{kl}(\mathbf{x}) \frac{\partial \varphi_i}{\partial x_k} \frac{\partial \varphi_j}{\partial x_l}.$$

So, since $\frac{\partial^2 w}{\partial \eta_1^2}$ will arise only from the principal part of the given PDE namely this part when you change your d-L equation into the new coordinate system, this $\frac{\partial^2 w}{\partial \eta_1^2}$ is a second order derivative it comes only through these terms. Therefore, you will find principal part how this transforms into the new coordinate system. This gives rise to this where each a_{ij} is this expression. So, go back to lecture 3.3 I think where we are done this change of coordinates.

(Refer Slide Time: 29:23)

Proof of Lemma (contd.)

Thus the analytic characterization of a characteristic surface Γ is obtained by setting the coefficient of $\frac{\partial^2 w}{\partial \eta_1^2}$ to zero, which yields

$$\sum_{k,l=1}^d a_{kl}(\mathbf{x}) \frac{\partial \varphi_1}{\partial x_k} \frac{\partial \varphi_1}{\partial x_l} = 0.$$

The above equation is nothing but the desired equation (26). $\nabla \varphi_1 \cdot (A \nabla \varphi_1) = 0$ \square

Thus, the analytic characterization of a characteristic surface γ is obtained by setting the coefficient of $\frac{\partial^2 w}{\partial \eta_1^2}$ to zero, that means this equal to 0. The above equation is nothing but what we want because this is $\text{grad } \varphi_1 \cdot A \text{ grad } \varphi_1 = 0$. Please ignore this number 26, this refers to the equation $\text{grad } \varphi_1 \cdot A \text{ grad } \varphi_1 = 0$.

(Refer Slide Time: 30:05)

Remark on the Lemma

- The previous lemma asserts that a hypersurface $\varphi_1(\mathbf{x}) = 0$ is a characteristic surface if the equation (26) is satisfied.
- We are interested in knowing whether the equation (d-L) has any characteristic surfaces.
- A partial answer is provided by the previous lemma. It says characteristic surface exists "when the equation (d-L) does not feature second order derivative w.r.t. one of the independent variables".
- If the missing variable is x_k , then $x_k = 0$ is a characteristic surface. \square

The previous lemma asserts that a hypersurface $\varphi_1(\mathbf{x}) = 0$ is a characteristic surface if the equation $\text{grad } \varphi_1 \cdot A \text{ grad } \varphi_1 = 0$ is satisfied. We are interested in knowing whether the equation has any characteristic surfaces. A partial answer is provided by the previous lemma, it also tells us that characteristic surface exists when the equation does not feature the second order derivative with respect to one of the independent variables.

The missing variable is x_k , that is $\frac{\partial^2 u}{\partial x_k^2}$ is missing, then $x_k = 0$ is a characteristic surface.

(Refer Slide Time: 30:49)

Example: Characteristic surfaces for Wave equation

Let Γ be a **regular hypersurface** defined as the level set of a smooth function $\varphi : \mathbb{R}^d \times \mathbb{R} \rightarrow \mathbb{R}$:

$$\Gamma = \{ (x, t) \in \mathbb{R}^d \times \mathbb{R} : \varphi(x, t) = 0 \},$$

and such that $\nabla_{x,t} \varphi(x, t) \neq 0$ for each $(x, t) \in \Gamma$.

Question. When will Γ be a characteristic surface for Wave equation?

Answer. The function φ must satisfy the equation

$$\nabla_{x,t} \varphi \cdot (A \nabla_{x,t} \varphi) = 0,$$

A is the diagonal matrix $\text{diag}(-c^2, \dots, -c^2, 1)$.

Let us look at an example, which is wave equation. So, we will try to determine characteristic surfaces for wave equation. So, let Γ be a regular hypersurface defined as the level set of a smooth function φ . Now, we have to be careful that wave equation we have x, t . So, therefore, $x \in \mathbb{R}^d$ and $t \in \mathbb{R}$, so, we write this. So, Γ is $\varphi(x, t) = 0$ and gradient should be non 0. Here gradient is not with respect to x, x and t just to clear any confusion we write this.

Gradient of x, t of φ of x, t is non 0 for each x, t in Γ . When will this Γ be a characteristic surface for wave equation? Answer; the function φ must satisfy this equation, $\nabla_{x,t} \varphi \cdot A \nabla_{x,t} \varphi = 0$ and what is A ? A is a diagonal matrix minus c^2 , minus c^2 , minus c^2 , ..., minus c^2 , 1. So, this is like $u_{tt} = c^2 u_{x_1 x_1} + c^2 u_{x_2 x_2} + \dots + c^2 u_{x_d x_d}$ and so on up to $c^2 u_{x_d x_d}$. So, these are d number this one, so this is a $(d+1) \times (d+1)$ diagonal matrix.

(Refer Slide Time: 32:07)

Example: Characteristic surfaces for Wave equation (contd.)

Thus the equation

$$\nabla_{\mathbf{x},t}\varphi(A\nabla_{\mathbf{x},t}\varphi) = 0$$

reduces to

$$\varphi_t^2 - c^2(\varphi_{x_1}^2 + \varphi_{x_2}^2 + \dots + \varphi_{x_d}^2) = 0$$

The above equation may also be written as

$$\varphi_t^2 - c^2 \|\nabla_{\mathbf{x}}\varphi\|^2 = 0.$$

The above equation may also be written as

$$\varphi_t = \pm c \|\nabla_{\mathbf{x}}\varphi\|.$$

So, this equation $\text{grad } \varphi \cdot A \text{ grad } \varphi$ reduces to this equation. This we can write because this is the Euclidean norm is nothing but this whole thing $\varphi_{x_1}^2 + \varphi_{x_2}^2 + \dots + \varphi_{x_d}^2$ is precisely norm $\text{grad } \varphi$ square Euclidean norm. So, this equation is exactly this. Now, I can get rid of the squares and I get this equation φ_t equals plus or minus c norm $\text{grad } \varphi$.

(Refer Slide Time: 32:38)

Example: Characteristic surfaces for Wave equation (contd.)

Recall from **Lecture 3.2** that when one of the independent variables is 'time', we would be interested in surfaces of the form

$$\Gamma : t = \psi(\mathbf{x})$$

In other words, we are interested in the level sets of functions of the form

$$\varphi(\mathbf{x}, t) = t - \psi(\mathbf{x})$$

Then the condition

$$\varphi_t = \pm c \|\nabla_{\mathbf{x}}\varphi\|$$

for Γ to be a characteristic surface for wave equation takes the form

$$\|\nabla_{\mathbf{x}}\psi\| = \frac{1}{c}$$

Recall from lecture 3.2 that when one of the independent variables is time which is true in the wave equation. We will be interested in they are the curves of the form $t = \psi$ of \mathbf{x} . Now, here we will be interested in surfaces $t = \psi$ of \mathbf{x} . So, we are not interested in arbitrary φ of $\mathbf{x} = 0$ but we are interested in $t = \psi$ of \mathbf{x} , we explained the reason why so? Because here; it is going

to give the location of the discontinuity.

That is what discussed in lecture 3.2, please go back there and understand again. So, in other words, we are interested in the level sets of functions of this time t - ψ x . How the equation changes? This equation for a hypersurface to be a characteristic surface will now in terms of ψ become this norm $\text{grad } x \psi = 1$ by c .

(Refer Slide Time: 33:35)

Example: Characteristic surfaces for Wave equation in one space dimension

When $d = 1$, the equation

$$\varphi_t^2 - c^2 (\varphi_{x_1}^2 + \varphi_{x_2}^2 + \dots + \varphi_{x_d}^2) = 0$$

becomes

$$\varphi_t^2 - c^2 \varphi_x^2 = 0.$$

The above equation may be factored as

$$(\varphi_t - c\varphi_x)(\varphi_t + c\varphi_x) = 0.$$

Two important families of solutions are the **characteristic lines**

$$x - ct = \text{constant} \quad x + ct = \text{constant} \quad \square$$

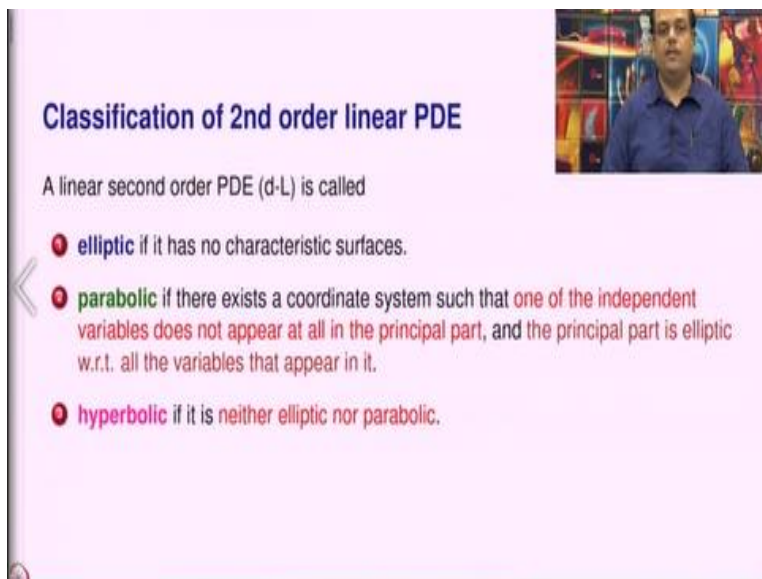

So, when $d = 1$ this equation is simply this equation. Now, we can factorize them like this $\psi_t^2 - c^2 \psi_x^2 = 0$, then you have $\psi_t - c \psi_x = 0$ and $\psi_t + c \psi_x = 0$ which gets cancelled. So, this is exactly the same as this factorization. So, two important families or solutions, the other characteristic lines $x - ct = \text{constant}$ and $x + ct = \text{constant}$. They come through solutions of these two equations, $\psi_t - c \psi_x = 0$ and $\psi_t + c \psi_x = 0$.

(Refer Slide Time: 34:19)

Classification of Linear equations

So, now, we are going to classify linear equations in more than two variables.

(Refer Slide Time: 34:24)

Classification of 2nd order linear PDE

A linear second order PDE (d-L) is called

- 1 **elliptic** if it has no characteristic surfaces.
- 2 **parabolic** if there exists a coordinate system such that **one of the independent variables does not appear at all in the principal part, and the principal part is elliptic w.r.t. all the variables that appear in it.**
- 3 **hyperbolic** if it is **neither elliptic nor parabolic.**

Based on characteristic surfaces. So, linear second order PDE is called elliptic, if it has no characteristic surfaces. Parabolic if there exists a coordinate system such that one of the independent variables does not appear at all in the principal part when the equation is written in that coordinate system and the principal part is elliptic with respect to all the variables that appear in it. Hyperbolic if we did not either elliptic nor parabolic.

(Refer Slide Time: 35:04)

A comment on the regular hypersurfaces

- Cauchy problem is posed on any hypersurface Γ . We did not define what it meant.
 - We went with the understanding of 2 dimensions, where it was a curve parametrized by one parameter.
 - Naturally, we understood by a hypersurface, a geometric object in \mathbb{R}^d which is parametrized by $d - 1$ parameters.
 - This is correct but we need to add **regularity assumptions** on Γ , as was done in 2 dimensions.
- In our analysis, we assumed that Γ is a level set along with regularity assumptions.
- Is every regular hypersurface, a level set? Are we missing something by analyzing only special cases?

So, now, we finish this lecture with a comment on the regular hyper surfaces that we started discussing at the beginning of the lecture when we introduced the Cauchy problem. So, Cauchy problem is posed on any hypersurface Γ . We did not even define what it is meant, we went with the understanding of what we know in two dimensions or it is a curve, tangent is defined at every point of Γ like that.

So, naturally we understood by hypersurface a geometric object in \mathbb{R}^d which is parameterize by $d - 1$ parameters is correct, but we need to add regularity assumptions as was done in two dimensions. In our analysis, we assumed that Γ is a level set. So, when we looked at the theorem and the lemma, we assumed a level set of a smooth function with a gradient being non 0. Now, is every regular hypersurface defined like this with the $d - 1$ parametric hypersurface.

Is it level set? Because if it is not so, we are not proved the theorem for a general hypersurface. So, are we missing something by analysing only maybe possibly a special case?

(Refer Slide Time: 36:18)

A comment on the surfaces (contd.)

Answers to the questions

- Regular surfaces may be defined in many different but (locally) equivalent ways.
- Thus no need to worry whether what we did is fine or not due to the equivalence.

For equivalent notions of regular surfaces, you may consult the book

Duistermaat and Kolk: **Multidimensional Real Analysis II Integration**

So, regular surface may be defined in many different but locally equivalent ways. There is no need to worry whether what we did is fine or not do not worry due to the equivalence. For equivalent notions of regular surface, there is a wonderful treatment in this book by Duistermaat and Kolk: multidimensional Real Analysis, part 2 integration. They have two books on multidimensional Real Analysis part 1 is differentiation, part 2 is integration. Of course, if you want to study the part 2, they often refer to part 1 also.

(Refer Slide Time: 36:57)

Examples

- 1 The equation $u_{xx} + u_{yy} + u_{zz} = 0$ is of elliptic type, since there are no associated characteristic surfaces.
 - Let $\Gamma : \varphi_1(x) = 0$ be a regular surface.
 - Γ is a characteristic surface if and only if φ_1 satisfies $\nabla \varphi_1 \cdot \nabla \varphi_1 = 0$. This implies that $\nabla \varphi_1 \equiv 0$.
 - This implies that Γ is not regular.
- 2 The equation $u_t = u_{xx} + u_{yy}$ is of parabolic type. Check the definition.
- 3 The equation $u_{tt} = u_{xx} + u_{yy}$ is of hyperbolic type. Not elliptic. Not parabolic.

Very beautifully written books. Now, let us look at some examples. This equation $u_{xx} + u_{yy} + u_{zz}$ is an elliptic type. Since there are no associated characteristic surfaces, how do I say it is elliptic? How to ask whether there are character surfaces? If there are none it is elliptic, there

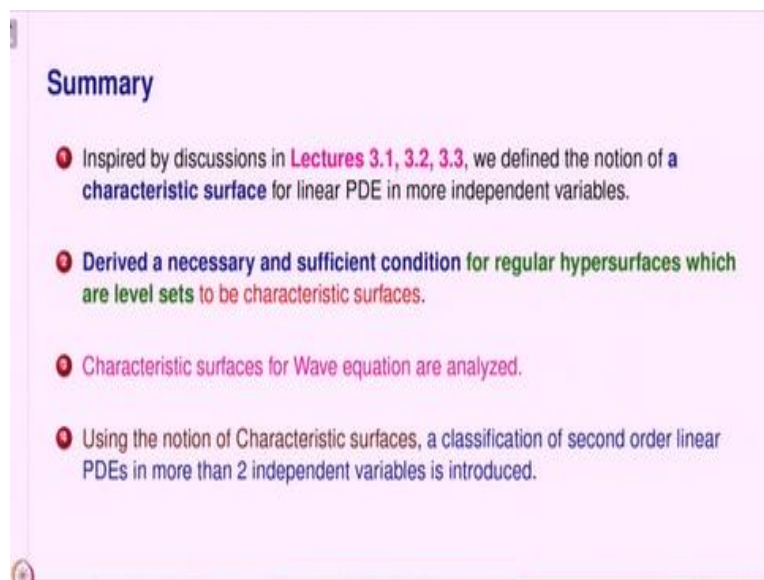

are none, why? Let us look at the equation set to be satisfied by hypersurface to be a characteristic surface.

So, assume this γ given by a level set be a regular surface, γ is a characteristic surface if and only if $\nabla \phi$ satisfies this equation $\nabla \phi \cdot \nabla \phi = 0$ because the A is identity here. The matrix here you got out of this equation is identity, because only u_{xx} , u_{yy} and u_{zz} are appear or norm exposure level disappear. So, off diagonal terms are 0 in the matrix A and diagonal terms are 1. So, you have this, but what is this? This is mode $\nabla \phi \cdot \nabla \phi = 0$.

So, this will be satisfied if and only if $\nabla \phi$ is 0, but we are assuming the set γ is a regular hypersurface. That means $\nabla \phi$ is never be 0. So, this tells us that there are no characteristic surfaces. Therefore, the equation is elliptic type. Look at this equation $u_t = u_{xx} + u_{yy}$, these are parabolic type. Check the definition. I will not discuss this, please check that by the definition that is not, it is a parabolic equation.

Now, this equation $u_{tt} = u_{xx} + u_{yy}$, it is a hyperbolic type. It is actually a wave equation in two squares dimensions, it is a hyperbolic type. Check that it is not elliptic is what we are doing it is not elliptic, it is not parabolic. And by definition, it is going to be hyperbolic.

(Refer Slide Time: 38:47)

Summary

- 1 Inspired by discussions in **Lectures 3.1, 3.2, 3.3**, we defined the notion of a **characteristic surface** for linear PDE in more independent variables.
- 2 **Derived a necessary and sufficient condition for regular hypersurfaces which are level sets to be characteristic surfaces.**
- 3 **Characteristic surfaces for Wave equation are analyzed.**
- 4 Using the notion of Characteristic surfaces, a classification of second order linear PDEs in more than 2 independent variables is introduced.

So, let us summarize, inspired by discussions of lectures 3.1, 3.2, 3.3. We define the notion of a

characteristic surface for linear PDE in more independent variables, derived a necessary and sufficient condition for regular hyper surfaces which are level sets to be characteristic surfaces. And characteristic surfaces for a wave equation are analysed. That is what we did towards the end.

Using the notion of characteristic surfaces, we have classified linear partial differential equations in more than two independent variables. Thank you.
