Wave Equation – A Mathematical for Vibrating Strings

So welcome to this lecture on wave equations we are going to start our study of wave equation starting from this lecture onwards. In this lecture we are going to derive an equation which governs the transfer's vibrations of a vibrating string.

(Refer Slide Time: 00:37)

Outline

Chapter 4: **Wave Equation**

- 1 Wave equation as a mathematical model for Vibrating strings
- 2 Maxwell's prediction: Light is an electromagnetic wave
- 3 Types of problems studied for wave equation
 - Cauchy problem (IVP)
 - Initial-boundary value problems (IBVP)

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 4.1 2 / 41

The outline for today's lecture is first we will derive wave equation as mathematical model for transfer's vibration of strings. Then we present them Maxwell's prediction that light is an electromagnetic wave it is based on wave equation actually. And we introduce 2 problems that we are going to study for the wave equation, one of them is called Cauchy problem or initial value problem and the second problem is Initial boundary value problems.

These are the 2 kinds of problems that we are going to study for wave equation mostly for 1 dimensional wave equation.

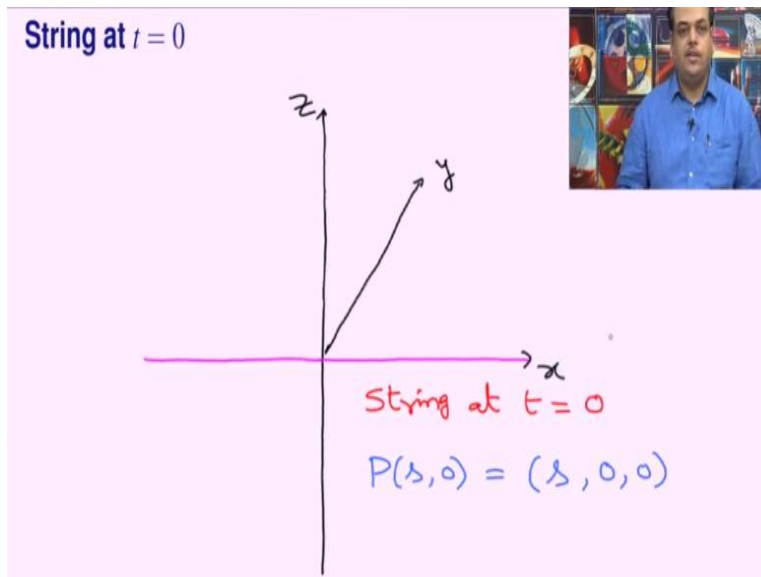

(Refer Slide Time: 01:19)

Wave equation

A mathematical model for vibrating strings

So wave equation as a mathematical model for vibrating strings.

(Refer Slide Time: 01:27)

So this is the picture of the string is line along the x axis at time $t = 0$ so therefore the position vector P of $s, 0$ is $s, 0, 0$ that means $x = s$ $y = 0$ $z = 0$. At this point of time you can imagine that this string is infinity length or finite length that does not matter.

(Refer Slide Time: 01:51)

Vibrating string

- Consider a **Perfectly flexible elastic string** lying along x -axis initially at time $t = 0$.
- The elastic string is assumed to be **one dimensional**. Thus points on the string may be described by a real parameter $s \in [0, l]$ (for a finite string) or $s \in \mathbb{R}$ (for an infinite string).
- Let $P(s, t) \in \mathbb{R}^3$ denote the position of a point s on the string at time instant t . That is,

$$P(s, t) := (X(s, t), Y(s, t), Z(s, t)), \quad 0 \leq s \leq l$$

String lies along x -axis means:

$$P(s, 0) := (s, 0, 0), \quad 0 \leq s \leq l$$

Goal: Derive an equation governing the vibrations of the string.

So consider a perfectly flexible elastic string lying along x axis at time $t = 0$. The elastic string is assumed to be 1 dimensional thus points on the string maybe described by real parameter s belongs to finite interval $0, l$ that the string is finite or s , in \mathbb{R} (()) (02:16) infinite string or even s in $0, \infty$ both are same actually. As far as this modeling goes but as far as the problems that are being it will be post s belongs to \mathbb{R} is different from s belongs to $0, \infty$ that we will see in the discussion of initial boundary value problems.

So let P of s, t it is a vector in \mathbb{R}^3 denote the position of a point s on the string as we have introduced here points on the string are identified with s . So it is a points s on the string $x = s$ and at the time instant t . So P of s, t is given by X of s, t Y of s, t Z of s, t and here and here we are writing a finite string. String lies along x axis means that P of $s, 0$ is $s, 0, 0$ these are we all have identified points on the string at time $t = 0$ we said $s, 0, 0$ is represents points on the string.

And when we s is between 0 and l it means we are considering a finite string so goal is to derive an equation which governs the vibrations of the string.

(Refer Slide Time: 03:35)

Vibrating string

- Pick a small segment of the string, say $a \leq s \leq b$, where $0 \leq a < b \leq l$.
- Assume that (mass)density of string is given by a function $\rho := \rho(s), 0 \leq s \leq l$.
- Therefore mass of the string segment $a \leq s \leq b$ is given by

$$\int_a^b \rho(s) ds.$$

Newton's second law says

Rate of change of momentum (of a particle) equals the net force acting on it

So how do we do that? Pick a small segment of the string let us say for s between a , and b . Of course a , and b itself is between 0 and l assume that it is density when we say density the usually in the first course in physics density is mass density. But in mathematical modeling will see there are lots of densities that are why we stress here it is a mass density of the string is given by a function ρ of s between 0 and l .

So therefore if you want to consider the mass what is the mass of the string between a , and b it is by integrating the density you get. Density as the dimension of a mass per unit volume and you are multiplying integrating over volume therefore you will get mass that is, understanding this. So whenever you have density we integrate you get that quantity. In this case you get the mass so Newton's second law it says that rate of change of momentum equals the net force acting on it.

(Refer Slide Time: 04:45)

Vibrating string: Rate of change of momentum

- The instantaneous velocity of the string at the point s is $\frac{\partial P}{\partial t}(s, t)$.

- Momentum of the string segment between $s = a$ and $s = b$ is

$$\int_a^b \rho(s) \frac{\partial P}{\partial t}(s, t) ds.$$

- Rate of change of momentum is

$$\frac{d}{dt} \int_a^b \rho(s) \frac{\partial P}{\partial t}(s, t) ds = \int_a^b \rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) ds.$$

So we would like to apply this Newton's second law so to apply Newton's second law we need know what is this rate of change of momentum and what are the forces acting? So momentum is related to the velocity so the instantaneous velocity of the string of the point is $\frac{\partial P}{\partial t}$ by $\frac{\partial P}{\partial t}$ at s, t . These are the time instant t momentum of string between $s = a$ and $s = b$ momentum is mass into velocity right.

Per mass we have a mass density we multiply the density with $\frac{\partial P}{\partial t}$ by $\frac{\partial P}{\partial t}$ and integrate we get the moment of the string segment between $s = a$, and $s = b$ is integral a to b ρ of s $\frac{\partial P}{\partial t}$ by $\frac{\partial P}{\partial t}$ of s, t ds . So what is rate of change of momentum $\frac{d}{dt}$ of this so $\frac{d}{dt}$ of this quantity that is the rate of change of momentum. So we have got one side of the Newton's second law so we need to see what is the other side?

Namely the forces acting on the segment a, b this can further be expanded $\frac{d}{dt}$ you can go inside and $\frac{\partial P}{\partial t}$ by $\frac{\partial P}{\partial t}$ become $\frac{\partial^2 P}{\partial t^2}$ by $\frac{\partial P}{\partial t}$ square.

(Refer Slide Time: 06:06)

Vibrating string: Net force on the segment $[a, b]$

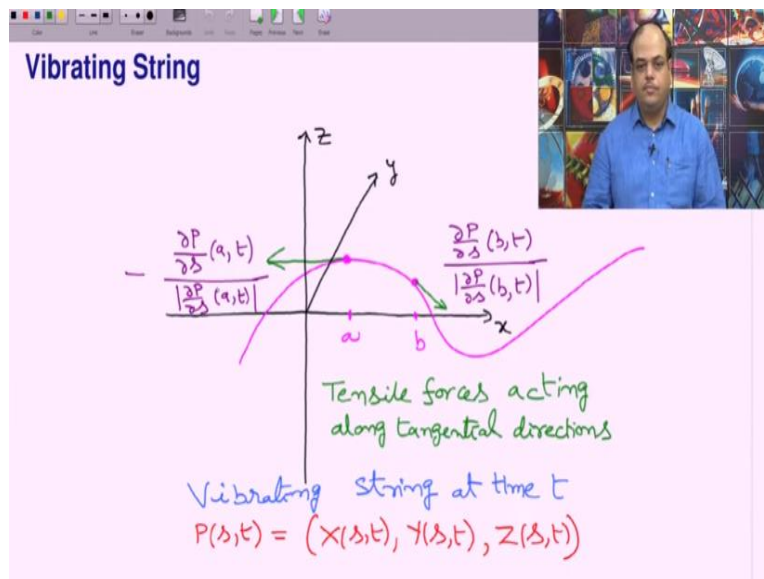

What are the forces acting on the string segment $[a, b]$?

There are two kinds of forces. They are

- 1 Internal forces: Tensile forces
- 2 External forces like gravity.

So net force acting on the segment a, b so there are 2 kinds of forces acting on the segment a, b what are those? First one is internal forces these are the tensile forces due to the tension in the string. And second is external forces like gravity and many other forces.

(Refer Slide Time: 06:30)

So this is the picture of the vibrating string these are time instant t vibrating string at time instant t this is a position $P(s, t)$ is $X(s, t)$, $Y(s, t)$, $Z(s, t)$. So this is the string that we are this is the segment a, b that we are considering. So at b there is somebody who is pulling in this direction but the rest of the string and at a this is this side of the string which is pulling in this direction so tensile force acting along tangential directions.

So therefore the tangential direction at this point is $\frac{\partial p}{\partial s}$ by $\frac{\partial p}{\partial s}$ and dividing that with its length will give us unit tangent vector in this direction is this. So at this point a it is in the opposite direction opposite means it is at this direction so that we model with minus sign here. Otherwise it is exactly the time initial direction.

(Refer Slide Time: 07:27)

Vibrating string: Net force on the segment $[a, b]$

Internal forces acting on the string segment $[a, b]$: Tensile forces

- Tensile force at $s = a$ exerted by the part of the string from $s = 0$ upto $s = a$.
 - It acts along tangential direction and is given by

$$-T^-(a, t) \frac{\frac{\partial p}{\partial s}(a, t)}{|\frac{\partial p}{\partial s}(a, t)|}$$

- Tensile force at $s = b$ exerted by the part of the string from $s = b$ to $s = l$.
 - It acts along tangential direction and is given by

$$T^+(b, t) \frac{\frac{\partial p}{\partial s}(b, t)}{|\frac{\partial p}{\partial s}(b, t)|}$$

So let us see what are internal forces which are acting on the string segment? What are we saw in the picture now we are going to write it down. So tensile force at $s = a$ is the segment a, b this is at one of the end at $s = a$. It is exerted by the part of the string from $s = 0$ to $s = a$. It acts along tangential direction and it is given by this is the tangential direction and this direction that we have chosen minus because we are at end point a , the left hand point in this interval and there is a number $T - a, t$.

This is what is a tensile and tensile force at $s = b$ similarly is a exerted by the part of the string from $s = b$ to l and it acts along tangential direction and is given by this is the tangential at the point b and $T + b, t$. So this minus and plus denote that this something coming from the left side on the string and this is coming from the right side of the string. We will soon see that they are the same at any point you do not have 2 values $t - a, t$ and $t + a, t$ no both are same we will see that soon.

(Refer Slide Time: 08:50)

Vibrating string: Net force on the segment $[a, b]$

External forces like gravity are represented by their force density

$$F(s, t) := (F_1(s, t), F_2(s, t), F_3(s, t))$$

Our current interest is **NOT** in modeling these external forces in detail.

Net force acting on the string segment $[a, b]$

$$\int_a^b \rho(s) F(s, t) ds + T^+(b, t) \frac{\frac{\partial P}{\partial s}(b, t)}{|\frac{\partial P}{\partial s}(b, t)|} - T^-(a, t) \frac{\frac{\partial P}{\partial s}(a, t)}{|\frac{\partial P}{\partial s}(a, t)|}$$

So now how do we model external forces their represented by the force density F $s, t = F_1, F_2, F_3$. Our current interest is not in modeling these external forces suppose you decide you want to affects some gravity then you would like to incorporate explicitly how the gravity forces apply on the string. So we are not interested in that we are generally taking any external force. So we are not going to model we are not going to consider external forces and what are the resultant F here we are not going to do that.

So net force acting on the string segment is here a to b $\rho(s) F(s, t) ds$ is a force these are force these are mass density this one is the force in this a, b and this is the internal forces.

(Refer Slide Time: 09:51)

Model for Vibrating string

Newton's second law says

Rate of change of momentum = the net force acting on it

Applying Newton's law (here we are treating the string segment $[a, b]$ as a particle!),

$$\int_a^b \rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) ds = \int_a^b \rho(s) F(s, t) ds + T^+(b, t) \frac{\frac{\partial P}{\partial s}(b, t)}{|\frac{\partial P}{\partial s}(b, t)|} - T^-(a, t) \frac{\frac{\partial P}{\partial s}(a, t)}{|\frac{\partial P}{\partial s}(a, t)|}$$

If we tend $b \rightarrow a$, then integral terms become zero. We get

$$T^-(a, t) = T^+(a, t)$$

Thus + and - may be dropped.

So one is external one is internal so Newton's second law says that rate of change of momentum is equal to the net force on it. So applying Newton's law so here we are treating the string segment as a particle so this is the rate of change of momentum and that equals the net force which is here. So this is the equation that we have got so far now suppose we tend $b = a$ in other words we are trying to as close to a particle as possible by taking this very small.

Imagine $a = b$ we are indeed particle so we tend b to a , and what will happen to this integrals? If inside integrals are reasonable this integral will be 0 this integral will also be 0. And when b goes to a this term goes to $T + a, t$ and b by a, t by modulus a, t P by modulus a, t . And this any way is a that equal to 0 and that will give us the $T -$ is same as $T +$. Therefore we draw plus and minus in the equation here so let us drop that.

(Refer Slide Time: 11:11)

Model for Vibrating string

Thus the equation

$$\int_a^b \rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) ds = \int_a^b \rho(s) F(s, t) ds + T(b, t) \frac{\partial P}{\partial s}(b, t) - T(a, t) \frac{\partial P}{\partial s}(a, t)$$

may be written as

$$\int_a^b \left(\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) - \rho(s) F(s, t) - \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right) \right) ds = 0.$$

So after dropping this is the equation that we have now we would like to write this also as an integral. This looks like some quantity evaluated b – same quantity evaluated at a so this looks like integral from a , to b of certain derivative of some point of time. So that is exactly this here this is da by da s of this into ds a , to b that will give you that this evaluated b minus this evaluated at a , which is exactly this so we can write this.

Now advantage is that all the terms are converted into integrals and we have this expression now this expression equal to 0 this equation holds no matter what a , and b is? Therefore the integrand must be 0 we have discussed this kind of issues while dealing with conservation loss.

(Refer Slide Time: 12:11)

Model for Vibrating string

Since a and b are arbitrary in the equation

$$\int_a^b \left(\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) - \rho(s) F(s, t) - \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right) \right) ds = 0,$$

we conclude

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right)$$

So since a and b are arbitrary in this equation the integrand must be 0 so this is an equation that we are got where P we have a second derivative with respect to t this is external force and P is here and then t there is something which is unknown. Otherwise that is if t is known this will be an equation for P a second order equation in T .

(Refer Slide Time: 12:43)

Model for Vibrating string

We obtained the equation

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right)$$

using a general principle, namely **Newton's law**.

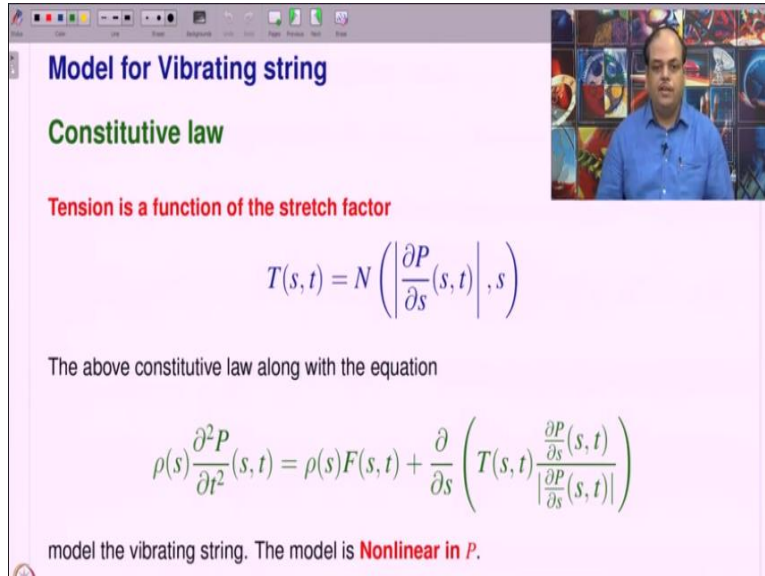

- In the above equation $T(s, t)$ depends on the specific nature of the material of the string.
- One needs to model/postulate the factors on which tension $T(s, t)$ depends, and the dependence. That is, we need to find a constitutive law.

So we have obtained this equation using a general principle which is Newton's second law and in the above equation T s, t is what the tension how the string is what material it is made up of it will depend on that. So 1 is to model or postulate the factors on which the tension depends and

the manner in which it depends. So we need to find a constitutive law. If you recall the modeling that we did for the traffic problem this is exactly that this is like modeling the road.

(Refer Slide Time: 13:21)

Model for Vibrating string

Constitutive law

Tension is a function of the stretch factor

$$T(s, t) = N \left(\left| \frac{\partial P}{\partial s}(s, t) \right|, s \right)$$

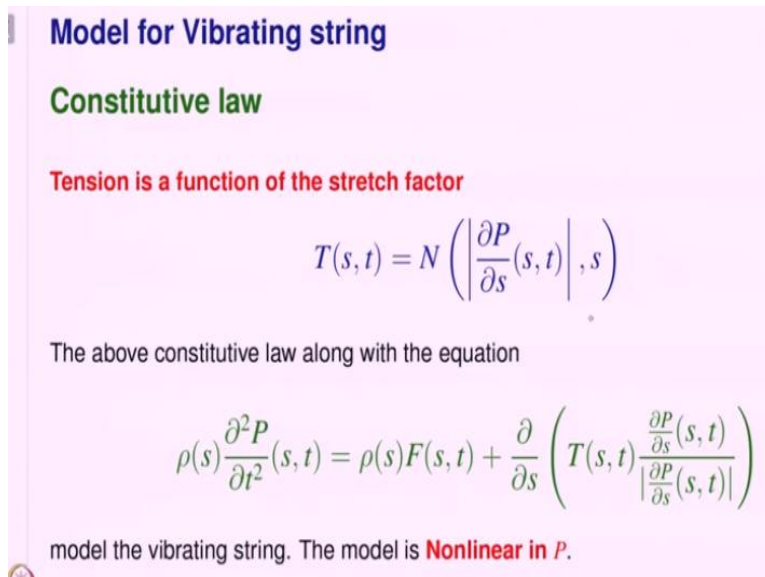

The above constitutive law along with the equation

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right)$$

model the vibrating string. The model is **Nonlinear in P**.

Tension is a function of the stretch factor this is an assumption so it is an function N of mod dau P by dau s s, t, s and the above constitutive law along with this differential equal which we got that they model a vibrating string. Of course it is a non-linear equation in P.

(Refer Slide Time: 13:50)

Model for Vibrating string

Constitutive law

Tension is a function of the stretch factor

$$T(s, t) = N \left(\left| \frac{\partial P}{\partial s}(s, t) \right|, s \right)$$

The above constitutive law along with the equation

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right)$$

model the vibrating string. The model is **Nonlinear in P**.

So the model for a vibrating string turns out to be highly non-linear so we would like to understand using simpler equations where we can actually perhaps solve the problem. So one

looks for model which approximates this model of course you need to assume more conditions on the nature of vibrations then we can get more simplified model.

(Refer Slide Time: 14:16)

Model for Vibrating string

Constitutive law

Tension is a function of the stretch factor

$$T(s, t) = N \left(\left| \frac{\partial P}{\partial s}(s, t) \right|, s \right)$$

The above constitutive law along with the equation

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\partial P}{\partial s}(s, t) \right)$$

model the vibrating string. The model is **Nonlinear in P**.

And then one as to see whether this model approximates the original model well these are the approximation go in practice. So in order to simplify the model we make a new assumption on the vibrations what is that assumption? Vibrations are small how do we model this vibrations are small? The $X(s, t)$ $Y(s, t)$ $Z(s, t)$ at time $t = 0$ X was s and Y and Z are 0 so we assume that it is a small chain from there.

So $s + \epsilon x$ of s, t this ϵy of s, t ϵz of s, t and tension also we model like this T naught background tension $T_0 +$ a small variation of that $\epsilon T_1(s, t)$ and $F(s, t)$ is also a small force $\epsilon f(s, t)$. Now we want to go and substitute in the equation that we have obtained here. Therefore we need to compute what $\frac{\partial P}{\partial s}$ by $\frac{\partial P}{\partial s}$ is.

(Refer Slide Time: 15:20)

Approximation to the model for a Vibrating string

The model for a vibrating string turned out to be highly nonlinear. In order to simplify the model, we make a new assumption on the vibrations.

Hypothesis: Vibrations are small

Let ε be small.

$$\begin{aligned} X(s, t) &= s + \varepsilon x(s, t) \\ Y(s, t) &= \varepsilon y(s, t) \\ Z(s, t) &= \varepsilon z(s, t) \\ T(s, t) &= T_0 + \varepsilon T_1(s, t) \\ F(s, t) &= \varepsilon f(s, t) \end{aligned}$$

Compute and verify:

$$\left| \frac{\partial P}{\partial s}(s, t) \right|^2 = \left(1 + \varepsilon \frac{\partial x}{\partial s}(s, t) \right)^2 + \left(\varepsilon \frac{\partial y}{\partial s}(s, t) \right)^2 + \left(\varepsilon \frac{\partial z}{\partial s}(s, t) \right)^2$$

So we will do those computation now so $\frac{\partial P}{\partial s}$ by $\frac{\partial}{\partial s}$ is derivative of this with respect to s is $1 + \varepsilon \frac{\partial x}{\partial s}$ that is what you see and similarly we get the other 2 terms.

(Refer Slide Time: 15:39)

Approximation to the model for a Vibrating string

Re-arranging the terms in

$$\left| \frac{\partial P}{\partial s}(s, t) \right|^2 = \left(1 + \varepsilon \frac{\partial x}{\partial s}(s, t) \right)^2 + \left(\varepsilon \frac{\partial y}{\partial s}(s, t) \right)^2 + \left(\varepsilon \frac{\partial z}{\partial s}(s, t) \right)^2,$$

we get

$$\left| \frac{\partial P}{\partial s}(s, t) \right|^2 = 1 + 2\varepsilon \frac{\partial x}{\partial s}(s, t) + \varepsilon^2 \left(\left(\frac{\partial x}{\partial s}(s, t) \right)^2 + \left(\frac{\partial y}{\partial s}(s, t) \right)^2 + \left(\frac{\partial z}{\partial s}(s, t) \right)^2 \right)$$

Using $(1 + a)^{1/2} = 1 + \frac{1}{2}a + O(a^2)$, we get

$$\left| \frac{\partial P}{\partial s}(s, t) \right| = 1 + \varepsilon \frac{\partial x}{\partial s}(s, t) + O(\varepsilon^2)$$

So rearranging the terms we get this expression now here we use this approximation $1 + a$ square root is $1 + \frac{1}{2}a + O(a^2)$. So this is $1 +$ this entire thing is a have a square here so I want to compute $\frac{\partial P}{\partial s}$ by $\frac{\partial}{\partial s}$. Therefore I need to square root on the both sides of this equation then I have square root of $1 +$ something square root is given by $1 + \frac{1}{2}a + O(a^2)$ plus order of a square. So that will give us this expression please pause for a while and do all this computation by yourself make sure that computations are correct so please do by yourself.

(Refer Slide Time: 16:29)

Approximation to the model for a Vibrating string

In view of

$$\left| \frac{\partial P}{\partial s}(s, t) \right| = 1 + \varepsilon \frac{\partial x}{\partial s}(s, t) + O(\varepsilon^2),$$

we have

$$\frac{\frac{\partial P}{\partial s}(s, t)}{\left| \frac{\partial P}{\partial s}(s, t) \right|} = \left(1 + O(\varepsilon^2), \varepsilon \frac{\partial y}{\partial s}(s, t) + O(\varepsilon^2), \varepsilon \frac{\partial z}{\partial s}(s, t) + O(\varepsilon^2) \right)$$

Now we move of this expression we need to compute to this right this is what appears in the equation dau P by dau s by modulus of that. So that will turn out to be a quantity of this type.

(Refer Slide Time: 16:42)

Approximation to the model for a Vibrating string

Thus the system

$$\rho(s) \frac{\partial^2 P}{\partial t^2}(s, t) = \rho(s) F(s, t) + \frac{\partial}{\partial s} \left(T(s, t) \frac{\frac{\partial P}{\partial s}(s, t)}{\left| \frac{\partial P}{\partial s}(s, t) \right|} \right)$$

takes the form

$$\begin{aligned} \varepsilon \rho(s) \frac{\partial^2 x}{\partial t^2}(s, t) &= \varepsilon \rho(s) f_1(s, t) + \frac{\partial}{\partial s} \left((T_0 + \varepsilon T_1(s, t)) (1 + O(\varepsilon^2)) \right) \\ \varepsilon \rho(s) \frac{\partial^2 y}{\partial t^2}(s, t) &= \varepsilon \rho(s) f_2(s, t) + \frac{\partial}{\partial s} \left((T_0 + \varepsilon T_1(s, t)) \left(\varepsilon \frac{\partial y}{\partial s}(s, t) + O(\varepsilon^2) \right) \right) \\ \varepsilon \rho(s) \frac{\partial^2 z}{\partial t^2}(s, t) &= \varepsilon \rho(s) f_3(s, t) + \frac{\partial}{\partial s} \left((T_0 + \varepsilon T_1(s, t)) \left(\varepsilon \frac{\partial z}{\partial s}(s, t) + O(\varepsilon^2) \right) \right) \end{aligned}$$

Now so this system now becomes this system so we have epsilon here there are epsilons square terms there are terms without epsilon. So what we do now is equate the coefficients of epsilon from LHS and RHS. Of course LHS coefficient of epsilon is simply these quantities rho dau 2 x by dau t square rho dau 2 y by dau t square, rho dau 2 z by dau t square. And here the first term will be rho f1 let us look at the first equation.

So coefficient of epsilon I mean that one which multiplies epsilon is this and here it is this. Now here we have to find out with t naught no here we get anything with epsilon you get 1. So you dau by dau s T1 you get.

(Refer Slide Time: 17:30)

Approximation to the model for a Vibrating string

Equating the coefficients of ϵ , we get the system

$$\rho(s) \frac{\partial^2 x}{\partial t^2}(s, t) = \rho(s) f_1(s, t) + \frac{\partial T_1}{\partial s}(s, t)$$

$$\rho(s) \frac{\partial^2 y}{\partial t^2}(s, t) = \rho(s) f_2(s, t) + T_0 \frac{\partial^2 y}{\partial s^2}(s, t)$$

$$\rho(s) \frac{\partial^2 z}{\partial t^2}(s, t) = \rho(s) f_3(s, t) + T_0 \frac{\partial^2 z}{\partial s^2}(s, t)$$

The last two equations describe **transverse vibrations of the string**, both are of the form

$$\frac{\partial^2 u}{\partial t^2} = f + \frac{T_0}{\rho(x)} \frac{\partial^2 u}{\partial x^2},$$

which is called **one-dimensional wave equation**.

So this is the first equation similar you can see that you get the other 2 equations. Now if you observe this the second and third equation they look similar they describe the transverse vibration of the string whereas the first one describes the longitudinal vibration of the string. So both look like this dau 2 u by dau t square you can put u = y or z you get these 2 equations equal to f + T naught by rho dau 2 u by dau x square. So this is called the, 1 dimensional wave equations.

(Refer Slide Time: 18:11)

Remark on the models for transverse vibrations of string

- We followed the treatment presented in the book Pinsky: Partial differential equations and boundary value problems with applications .
- For a good account of derivations of equations governing transverse vibrations, see the article on On the String Equation of Narasimha by A.S. Vasudeva Murthy (ASVM) in the TRIM series book *Connected at Infinity II: A selection of Mathematics by Indians*, Hindustan book agency (2013).
- R. Narasimha: *The equations of motion for a flexible string*, *J. Sound and Vibration*, 10, 350 (1969) derived a model for transverse vibrations of a string. Discussion on this is found in the article by ASVM given above.

So small remark on models for transverse vibration of string so, we followed the treatment presented in the book by Pinsky on partial differential equations and boundary value column with applications this is the title of the book of Pinsky. For a good account of derivations of equations governing transverse; vibrations of that matter vibration of strings. See the article on the string equation by of Narasimha by A. S, Vasudeva Murthy in this book connected at infinity a selection of mathematics by Indians.

It is TRIM series book published by Hindustan book agency that is where we describe an equation of a Narasimha and this is actually the reference to the original paper of Narasimha. Derived a model for transverse vibrations of a string the different between a various derivations of transverse vibrations of a string and these which I have quoted here is that. While deriving transverse vibrations people assume that there are no longitudinal vibration which affect on that.

Whereas these models take into that account and then further simplify therefore you see you start with a very correct physical assumptions derive a model and then you know what assumptions you are making to get the equation that you get. How the equations get simplified under more assumptions? So that is the remark on this and discussion on this equation is what is there in this particle by ASVM.

(Refer Slide Time: 19:54)

Maxwell's prediction

Electromagnetic wave nature of Light

Now let us turn our attention to Maxwell's prediction that electromagnetic wave nature of light.
(Refer Slide Time: 20:02)

Maxwell's Equations

$$\text{curl } \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t}$$
$$\text{curl } \mathbf{B} = \mu_0 \epsilon_0 \frac{\partial \mathbf{E}}{\partial t}$$
$$\text{div } \mathbf{B} = 0$$
$$\text{div } \mathbf{E} = 0$$

ϵ_0 is the permittivity of free space, and μ_0 is the permeability of free space.

So these are what are called Maxwell's equations. I will not read out is electric field is magnetic field u naught and epsilon naught are permeability and permittivity irrespectively. So divergence of $\mathbf{E} = 0$ divergence of $\mathbf{B} = 0$ and there are equations for curl. So this is a first order system of equations.

(Refer Slide Time: 20:27)

Maxwell to Wave

Applying curl on both sides of the equation

$$\text{curl } \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t},$$

we get

$$\text{curl}(\text{curl } \mathbf{E}) = -\frac{\partial}{\partial t} \text{curl } \mathbf{B}.$$

Using the formula $\text{curl}(\text{curl } \mathbf{E}) = -\Delta \mathbf{E} + \nabla(\nabla \cdot \mathbf{E})$ and the second equation in the Maxwell's system, we get

$$\Delta \mathbf{E} = \mu_0 \epsilon_0 \frac{\partial^2 \mathbf{E}}{\partial t^2}$$

Now applying curl to both sides of the first equation so we get curl-curl $\mathbf{E} = -\text{dau by dau t of curl B}$. Now we have a formula on vector calculus curl-curl is nothing but minus Laplacian this is $\text{dau}^2 \mathbf{E}$ by $\text{dau x square} + \text{dau t by dau y square} + \text{dau t by da z square}$ those are these is Laplacian. And this is, gradient of divergence into divergence and the second equation in the Maxwell system which is for curl \mathbf{B} that is a second equation use this equations and we end up this gets simplified to this equation.

Laplacian $\mathbf{E} = \mu_0 \epsilon_0 \text{dau}^2 \mathbf{E}$ by dau t square note this is system of 3 equations even E_2, E_3 of course they are all same.

(Refer Slide Time: 21:19)

Maxwell to Wave

On substituting for derivatives of \mathbf{E} in the equation

$$\frac{\partial^2 \mathbf{E}}{\partial x^2} = \mu_0 \epsilon_0 \frac{\partial^2 \mathbf{E}}{\partial t^2},$$

we get

$$v = \frac{1}{\sqrt{\mu_0 \epsilon_0}}$$

Now when $d = 1$ let us try these equations as solution of this type so now it is not a Laplacian E this simply $\nabla^2 E = \mu \frac{\partial^2 E}{\partial t^2}$. So we try a solution of this form substitute in this equation here wave velocity is v and a wave length is λ . Now just compute what is $\nabla^2 E$ by $\frac{\partial^2 E}{\partial t^2}$ this what you get \sin becomes \cos , \cos becomes minus \sin that is why you get minus every time we differentiate with respect to t you pick up minus μ by λ^2 so square.

Similarly $\nabla^2 E = \mu \frac{\partial^2 E}{\partial t^2}$ you can compute go back to substitute in this equation you get that velocity is $\frac{1}{\sqrt{\mu \epsilon_0}}$.

(Refer Slide Time: 22:15)

Maxwell to Wave

By the time Maxwell did the above computations,

- the values of ϵ_0, μ_0 were known from experiments.
- The quantity $\frac{1}{\sqrt{\mu_0 \epsilon_0}}$ had dimensions of velocity is also known.

To the surprise of Maxwell, with the known values of ϵ_0, μ_0 , he obtained

$$v = \frac{1}{\sqrt{\mu_0 \epsilon_0}} \approx 3.107 \times 10^8 \text{ m/sec.}$$

which is close to the **speed of the light**.

Now by the time Maxwell did the above computations the values of ϵ_0, μ_0 are known from experiments and this quantity $\frac{1}{\sqrt{\mu_0 \epsilon_0}}$ it is known to have the dimensions of velocity that is also known. But thanks to the computations of Maxwell with these known values of ϵ_0, μ_0 he obtained that this velocity is approximately equal to 3.107×10^8 meters per second which is close to the speed of light.

(Refer Slide Time: 22:51)

Maxwell's prediction on Light

- Maxwell predicted that **Light is a form of electromagnetic radiation.**
 - This was possible thanks to his computations using Maxwell's equations.
 - The computations led to a Wave equation which admits waves moving with speed of light as its solutions.
 - This highlights the **importance of Wave equation!**
- Existence of electromagnetic radiation was later proved experimentally by **Hertz.**

So Maxwell predicted that light is a form of electromagnetic radiation of course this was possible thanks to its computation using Maxwell's equations. The computations led to wave equation which admits wave moving with speed of light as its solutions. This highlights the importance of wave equation of course existence of electromagnetic radiation was later proved experimentally by Hertz.

Types of problems studied for wave equation

Cauchy problem in full space a.k.a. Initial value problem

Now let us discuss briefly the types of problems studied for wave equation the first problem is Cauchy problem in full space it is also known as initial value problem.

(Refer Slide Time: 23:34)

Wave operator in d space variables

$$\square_d u \equiv u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_d x_d})$$

- The operator \square_d is called the **d -dimensional wave operator**.
- It is also known as **d 'Alembertian operator**.

So wave operators in d space variables so let us introduce wave equations of course we have derived wave equations in one space dimension using strings. But you can write wave operator in d space where it is which is nothing but $U_{tt} - C^2$ into Laplacian u is precisely this $\square_d u = u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_d x_d})$. This is the wave operator these called the d dimensional wave operator when we say refer to the word dimension what we mean here is the space dimension x_1 up to x_d .

So the equation for the string was a 1 dimensional wave operator so this square d this is the notation used square d stands for this operator. It is also known as d 'Alebertian operator.

(Refer Slide Time: 24:36)

Cauchy problem for Wave equation

Given functions $\varphi, \psi : \mathbb{R}^d \rightarrow \mathbb{R}$ and $f : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R}$, Cauchy problem is to find a solution to

$$\begin{aligned} \square_d u \equiv u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_d x_d}) &= f(\mathbf{x}, t), & \mathbf{x} \in \mathbb{R}^d, t > 0, \\ u(\mathbf{x}, 0) &= \varphi(\mathbf{x}), & \mathbf{x} \in \mathbb{R}^d, \\ u_t(\mathbf{x}, 0) &= \psi(\mathbf{x}), & \mathbf{x} \in \mathbb{R}^d. \end{aligned} \quad (1)$$

where \mathbf{x} denotes the point $(x_1, x_2, \dots, x_d) \in \mathbb{R}^d$, and $c > 0$.

So what is Cauchy problem for wave equation so given functions phi psi and f suitably? Cauchy problem is to find a solution to this equation what is this equation? This is a wave operator equal to f and you are given u at x=0 to be phi and u_t at x=0 to be psi. So f phi psi are supplied find a solution u satisfying all the 3 equations the bold phase x stands for x1, x2, ..., xd which is an R^d and c is positive number.

(Refer Slide Time: 25:13)

Cauchy problem for Wave equation

Given functions $\varphi, \psi : \mathbb{R}^d \rightarrow \mathbb{R}$ and $f : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R}$, Cauchy problem is to find a solution to

$$\begin{aligned} \square_d u &\equiv u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_d x_d}) = f(x, t), & x \in \mathbb{R}^d, t > 0, \\ u(x, 0) &= \varphi(x), & x \in \mathbb{R}^d, \\ u_t(x, 0) &= \psi(x), & x \in \mathbb{R}^d. \end{aligned} \quad (1)$$

where x denotes the point $(x_1, x_2, \dots, x_d) \in \mathbb{R}^d$, and $c > 0$.

So we need to define what is the meaning of the solution? Solution how you should be a function you should be as many times differentiable as you see the derivatives here 2 derivatives so I want to the function to be 2 times continuously differentiable and I want this condition to be satisfied these 2 conditions and that is it. But if you see here this equation is valid in R^d cross (0, infinity) so, the function must be defined R^d cross open (0, infinity).

But here I am asking the value at 0 should make sense that means you should be continuous on R^d cross closed [0, infinity) and similarly u_t must be continuous R^d cross closed [0, infinity). So that this makes sense and then we can ask it should be equal to the given sin that is all.

(Refer Slide Time: 26:07)

Definition of a Classical Solution

A function $u : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R}$ is said to be a classical solution to the Cauchy problem (1) if the function u

- 1 is twice continuously differentiable on its domain $\mathbb{R}^d \times (0, \infty)$, and the equality $\square_d u(x, t) = f(x, t)$ holds for every $(x, t) \in \mathbb{R}^d \times (0, \infty)$,
- 2 is continuous on the domain $\mathbb{R}^d \times [0, \infty)$ so that $u(x, 0)$ is meaningful and the equality $u(x, 0) = \varphi(x)$ holds for every $x \in \mathbb{R}^d$,
- 3 is such that the function u_t is continuous on the domain $\mathbb{R}^d \times [0, \infty)$ so that $u_t(x, 0)$ is meaningful and the equality $u_t(x, 0) = \psi(x)$ holds for every $x \in \mathbb{R}^d$.

Notion of a classical solution on the domain $\mathbb{R}^d \times (0, T)$ for $T > 0$ may be analogously defined by replacing ∞ with T in the above definition.

So a function is said to be a classical solution to the Cauchy problem if the function is twice continuously differentiable on its domain. And the equality holds at every points in $\mathbb{R}^d + 0$ infinity and it is continuous on this domain note here I have included a closed 0. Whereas here we have only so both are different conditions. This does not imply this continuity on open said does not mean it is continuous up to it is closure.

So that $u(x, 0)$ is meaningful and then the equality is equal to $\varphi(x)$ holds for every x in \mathbb{R}^d . Similarly the u_t should be continuous on this domain so that u_t of any x comma 0 makes sense and it is equal to $\psi(x)$ and that holds. We can modify by replacing infinity with the T what you mean by classical solution on domain \mathbb{R}^d cross $0, T$.

(Refer Slide Time: 27:18)

Observation

A solution u to the Cauchy problem (1) may be obtained as

$$u = v + \tilde{v}$$

where v is a solution to the Cauchy problem for homogeneous wave equation and \tilde{v} is a solution to the nonhomogeneous wave equation with zero initial conditions. That is,

$$\square_d v = 0, \quad x \in \mathbb{R}^d, t > 0,$$

$$v(x, 0) = \varphi(x), \quad x \in \mathbb{R}^d,$$

$$v_t(x, 0) = \psi(x), \quad x \in \mathbb{R}^d,$$

$$\square_d \tilde{v} = f(x, t), \quad x \in \mathbb{R}^d, t > 0,$$

$$\tilde{v}(x, 0) = 0, \quad x \in \mathbb{R}^d,$$

$$\tilde{v}_t(x, 0) = 0, \quad x \in \mathbb{R}^d.$$

Observation is that the d'Alembertian operator is a linear operator that means you apply a square d to $u + v$ you get square d $u +$ square d v . Thus a solution u to the Cauchy problem were stated earlier on the previous lights that may be obtained as sum of 2 things $v + v$ tilde what are the properties? v solves the Cauchy problem for homogenous wave equation that means the right hand side f is 0 but φ and ψ are there.

And v tilde solves non-homogenous equation that means f is here but 0 initial conditions that mean φ and ψ are 0. So that is precisely this v solves this problem notice here the right hand side in equation is switched off it is becomes 0 whereas here f is represent by the initial condition is switched off the Cauchy problem. If we add $v + v$ tilde because the linearity square d $v + v$ tilde will be f because it will be $0 + f$ that will be f . And $x, 0$ will be $\varphi + 0$ it will be φ and v_t will be $\psi + v_t$ tilde of t will be $\psi + 0$ which is ψ .

(Refer Slide Time: 28:33)

Plan of action for solving the Cauchy problem

- Solve the Cauchy problem for Homogeneous wave equation.
 - For $d = 1, 2, 3$, we will derive formulae for the solutions.
- Solve the non-homogeneous wave equation with zero Cauchy data.
 - We use a general method called **Duhamel principle**.
 - Duhamel principle tells us that non-homogeneous equations with zero Cauchy data may be solved using solutions to the corresponding homogeneous equations with non-zero Cauchy data.

So therefore plan of action for solving the Cauchy problem is solve it for a homogenous wave equation first. That is what we will $d = 1, 2, 3$ we will derive actually the formulae which are known by various names and we solve the non-homogenous wave equation with 0 Cauchy data. For that we use the general method called Duhamel principle. That Duhamel principle tells us that non-homogenous equations can be solved using solutions of homogenous equations.

(Refer Slide Time: 29:10)

Types of problems studied for wave equation

Initial-boundary value problems (IBVP)

And the second type of problem is initial boundary value problems.

(Refer Slide Time: 29:14)

IBVP

An IBVP for Wave equation consists of solving

$$\begin{aligned}u_{tt} - c^2 \Delta u &= 0 \text{ for } \mathbf{x} \in \Omega, t > 0, \\u(\mathbf{x}, 0) &= \varphi(\mathbf{x}) \text{ for } \mathbf{x} \in \Omega, \\u_t(\mathbf{x}, 0) &= \psi(\mathbf{x}) \text{ for } \mathbf{x} \in \Omega, \\u(\mathbf{x}, t) &= 0 \text{ for } \mathbf{x} \in \partial\Omega, t \geq 0,\end{aligned}$$

where Ω is a bounded domain in \mathbb{R}^d ($d \geq 2$), and φ, ψ are given functions. One could consider other boundary conditions in place of $u(\mathbf{x}, t) = 0$ for $\mathbf{x} \in \partial\Omega$

IBVPs are more complicated than Cauchy problem posed in full space \mathbb{R}^d due to the presence of boundary $\partial\Omega$.

This is applicable when the equation is posed not x in \mathbb{R}^d but x in Ω is a bounded domain \mathbb{R}^d you want to equations to be satisfied on Ω that there could be a right hand side f here no problem there could be a right hand side f here. Similarly there could be $u_t(\mathbf{x}, 0) = \psi(\mathbf{x})$ this is just an example of IBVP so these are the initial condition the first 2 conditions here are initial conditions equation initial condition and this is a boundary condition. $u = 0$ on the boundary of Ω for all times.

So these are the initial boundary value problems and we will also solve initial boundary value problem when Ω is a subset of \mathbb{R}^1 and interval. Of course one could consider more general boundary conditions than u for example one could describe the normal derivative of u on the boundary. Or you can prescribe a combination of u and (\cdot) (30:17) derivative is nothing but the normal derivative $\frac{\partial u}{\partial n}$ by $\frac{\partial u}{\partial n} = \text{grad } u \cdot \mathbf{n}$ on the boundary.

So IBVP's are more complicated than Cauchy problems which are posed on full space due to the presence of the boundary Ω .

(Refer Slide Time: 30:36)

Summary

Summary

- 1 Derived a mathematical model for Vibrating strings.
 - It was a nonlinear model
- 2 Under the assumption of **Small vibrations**, the nonlinear model reduced to **Linear wave equation**.
- 3 Discussed the computations leading to Maxwell's prediction of **Electromagnetic wave nature of Light**.
- 4 Introduced Cauchy problem associated to Wave equation. Outlined a plan of action for solving it.
- 5 Introduced Initial-boundary value problem associated to wave equation.

So let us summarize what we did? We derived a mathematical model for vibrating strings it was a non-linear model. Under the assumption of small vibrations the non-linear model reduced to linear wave equation and we discussed the computation which led Maxwell to predict electromagnetic wave nature of the light. And we introduced a Cauchy problem associated to wave equation outline a planned of action for solving it. And we introduce initial boundary value problem associated to wave equation thank you.
