Wave Equation in d space dimensions
Equivalent Cauchy problems via Spherical means

Welcome in this lecture we are going to discuss Cauchy problem for wave equation in d space dimensions in fact we are not going to discuss fully what we are going to do is? We are going to reduce this Cauchy problem in d space dimensions to a Cauchy problem for PD which is having just 2 independent variables that we will do via spherical means.

(Refer Slide Time: 0:46)

Outline for today's lecture is we start with statement of Cauchy problem for the wave equation in d space dimension. Then we introduce spherical means and a formula known Darboux formula associated to that then we reduce the Cauchy problem for the wave equation to an equivalent Cauchy problem.

(Refer Slide Time: 01:09)

Cauchy problem for d dimensional wave equation

Given functions $\varphi, \psi : \mathbb{R}^d \rightarrow \mathbb{R}$, Solve

$$\square_d u \equiv u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_d x_d}) = 0, \quad \mathbf{x} \in \mathbb{R}^d, t > 0, \quad (\text{WE-dd})$$

$$u(\mathbf{x}, 0) = \varphi(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d, \quad (\text{IC-1})$$

$$u_t(\mathbf{x}, 0) = \psi(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d, \quad (\text{IC-2})$$

where $\mathbf{x} = (x_1, x_2, \dots, x_d)$.

So Cauchy problem for d dimensional wave equation reads as follows given functions φ and ψ solve the homogenous wave equation in d space dimension have you see x_1, x_2, x_d are the space dimensions are the space variables. And u of \mathbf{x} at $t = 0$ is φ and u_t of \mathbf{x} at $t = 0$ is ψ . We are not yet stating what is regularity or the smoothness of the functions φ and ψ required. We will see them later on.

(Refer Slide Time: 01:42)

Key idea to solve Cauchy problem

➊ Reduce the Cauchy problem to an equivalent Cauchy problem in one space dimension.

• **Advantage:** The number of space dimensions drop from d to **one**.

• **Tool:** Method of spherical means.

So key idea to solve this Cauchy problem is reduce the Cauchy problem to an equivalent Cauchy problem in one space dimension advantage the number of space dimension drop from d to 1. And the tool is method of spherical means.

(Refer Slide Time: 02:05)

Key idea to solve Cauchy problem (contd.)

- ② When $d = 3$, the new Cauchy problem may be transformed to that of the one dimensional wave equation after a change of dependent variable.
 - d'Alembert formula gives the solution to the Cauchy problem for the one dimensional wave equation.
 - A solution of Cauchy problem for the 3 dimensional wave equation is recovered from the d'Alembert formula.
- ③ In this lecture, we derive the equivalent Cauchy problem, valid for d space dimensions.

So when $d = 3$ the new Cauchy problem which we have obtained it can be transformed to, one dimensional wave equation. Cauchy problem for one dimensional wave equation of course after a change dependent variable which is straight forward. And then we are on with the d'Alembert formula which uses the solution to the Cauchy problem for the one dimensional wave equation. And retrieve the solution to the 3 dimensional wave equation; the Cauchy problem solution from the d'Alembert formula that we get here.

So in this lecture we confined ourselves to deriving the equivalent Cauchy problem valid for all space dimensions.

(Refer Slide Time: 02:56)

A few computations involving
Multiple integrals

So let us see a few computations and notations involving multiple integrals.

(Refer Slide Time: 03:03)

Notations

- We deal with functions of d real variables (not necessarily $d = 3$).
- Euclidean norm of $\mathbf{x} := (x_1, x_2, \dots, x_d) \in \mathbb{R}^d$ is denoted by $\|\mathbf{x}\| := \sqrt{x_1^2 + x_2^2 + \dots + x_d^2}$
- $B(\mathbf{x}; \rho)$ denotes the open ball of radius $\rho > 0$, with center at $\mathbf{x} \in \mathbb{R}^d$. That is,
$$B(\mathbf{x}; \rho) := \{\mathbf{y} \in \mathbb{R}^d : \|\mathbf{x} - \mathbf{y}\| < \rho\}$$
- $S(\mathbf{x}; \rho)$ denotes the sphere having radius $\rho > 0$, with center at $\mathbf{x} \in \mathbb{R}^d$. That is,
$$S(\mathbf{x}; \rho) := \{\mathbf{y} \in \mathbb{R}^d : \|\mathbf{x} - \mathbf{y}\| = \rho\}$$
- The usage of the word **sphere** is slightly confusing. Note that 'hollow sphere' is called sphere in our course, 'solid sphere' is the union of the ball and the sphere'.

We will start with notations so we deal with functions of d real variables not necessarily $d = 3$. Euclidean norm of a vector \mathbf{x} is denoted by norm \mathbf{x} that is notation and that is given by square root of x_1 square + x_2 square + up to + x_d square. The usual length of the vector \mathbf{x} B of \mathbf{x} , ρ it denotes the open ball of the radius ρ of course radius as a positive and with center at \mathbf{x} . So B of \mathbf{x} , ρ is set of all \mathbf{y} in \mathbb{R}^d whose distance from \mathbf{x} is at most ρ that is $\|\mathbf{x} - \mathbf{y}\|$ is less than ρ .

S of \mathbf{x} , ρ denotes this sphere having radius ρ and center at \mathbf{x} that is S of \mathbf{x} ρ is \mathbf{y} in \mathbb{R}^d such that $\|\mathbf{x} - \mathbf{y}\|$ equal to ρ . The usage of the word sphere is slightly confusing because from our high school by sphere what we mean is a sphere which is in this case actually the ball union this sphere the boundary of the ball is this sphere both of them you should take the union you get the so called solid is sphere.

So what we mean by sphere here is the hollow sphere is called sphere in our course in fact that is shown in any advanced mathematical courses. And solid sphere is the union of the ball under this sphere.

(Refer Slide Time: 04:45)

Notations (contd.)

- ω_d denotes the measure of the unit sphere $S(0; 1)$ in \mathbb{R}^d
 - ω_2 is the perimeter of the circle of radius 1 having centre at origin. $\omega_2 = 2\pi$.
 - ω_3 is the surface area of the sphere of radius 1 having centre at origin. $\omega_3 = 4\pi$.
 - $|S(x; \rho)| = \rho^{d-1} \omega_d$
- $d\omega$ is used to denote the surface measure on $S(0; 1)$.
- A generic notation $d\sigma$ is used to denote the surface measure on any sphere. It varies with radius of the sphere.

So you should not get confused now ω_d denotes the measure of the unit sphere $S(0, 1)$ in \mathbb{R}^d . ω_2 for example $d = 2$ ω_2 is a perimeter of the circle of radius 1 therefore it is 2π . ω_3 is surface area of sphere of radius 1 and that is 4π we also have this relation which connects the surface area of the unit sphere to surface area of sphere of any radius. So this is a surface area of the sphere of radius ρ that is ρ^{d-1} times the surface area of the unit sphere.

$d\omega$ is used to denote the surface measure on $S(0, 1)$ we are going to deal with various integrals as $S(0, 1)$. So we write $d\omega$ denotes the surface measure now we use a generic notation $d\sigma$ to denote surface measure on any hyper surface in our context since we are dealing only with spheres it is a $d\sigma$ is used to denote the surface measure on any sphere. Of course it varies from sphere to sphere in fact it varies with the radius of the sphere.

(Refer Slide Time: 06:06)

Multiple integrals: Change of variables, Integration by parts

Consider the following change of variables

$$\begin{aligned} B(\mathbf{x}; \rho) &\longrightarrow B(\mathbf{0}; 1) \\ \mathbf{y} &\longmapsto \frac{\mathbf{y} - \mathbf{x}}{\rho} \end{aligned}$$

Given a function $g : B(\mathbf{x}; \rho) \rightarrow \mathbb{R}$, define a function $w := w(\mathbf{z})$ by

$$w : B(\mathbf{0}; 1) \rightarrow \mathbb{R}, \quad w(\mathbf{z}) = g(\mathbf{x} + \rho\mathbf{z})$$

The function g can be expressed in terms of w by

$$g(\mathbf{y}) = w\left(\frac{\mathbf{y} - \mathbf{x}}{\rho}\right).$$

Now let us the change of variables from so it is a mapping from B of \mathbf{x} rho to B 0, 1 \mathbf{y} in B of \mathbf{x} , rho map to $\mathbf{y} - \mathbf{x}$ by rho. So the ball of radius rho \mathbf{x} will be going to the ball of radius 1 and center 0 under this mapping. It is of course it is an infeasible mapping so given a function g defined on B of \mathbf{x} rho we can define a function which is define on B of 0, 1 that is 2 of \mathbf{z} for \mathbf{z} in B 0, 1 by g of $\mathbf{x} + \rho\mathbf{z}$. So a function define here can be transferred to function here and vice versa so g of \mathbf{y} is given by w of $\mathbf{y} - \mathbf{x}$ by rho in terms of w .

(Refer Slide Time: 07:01)

Multiple integrals: Change of variables, Integration by parts

The equation

$$g(\mathbf{y}) = w\left(\frac{\mathbf{y} - \mathbf{x}}{\rho}\right),$$

gives rise to (using Chain rule)

$$\begin{aligned} \nabla_{\mathbf{y}} g(\mathbf{y}) &= \rho^{-1} \nabla_{\mathbf{z}} w\left(\frac{\mathbf{y} - \mathbf{x}}{\rho}\right) \\ \Delta_{\mathbf{y}} g(\mathbf{y}) &= \rho^{-2} \Delta_{\mathbf{z}} w\left(\frac{\mathbf{y} - \mathbf{x}}{\rho}\right). \end{aligned}$$

So this equation gives rise to the following equations of course chain rule so we are going to differentiate both sides with respect to \mathbf{y} . So gradient with respect to \mathbf{y} is gradient of w with respect to \mathbf{z} and gradient of the inside quantity which is $\mathbf{y} - \mathbf{x}$ by rho with respect to \mathbf{y} that will

give you 1 by rho that is why rho inverse. And Laplacian consist of second order derivatives so we get one more rho, inverse.

So we have rho power -2 into Laplacian in z of w evaluated at y – x by rho so we have to be as I told you we have to be comfortable with using a chain rule particularly when there are change of variables involved.

(Refer Slide Time: 07:46)

Multiple integrals: Change of variables, Integration by parts (contd.)

In view of $dy = \rho^d dz$, and $\Delta_y g(y) = \rho^{-2} \Delta_z w\left(\frac{y-x}{\rho}\right)$, we have

$$\begin{aligned} \int_{B(x;\rho)} \Delta_y g(y) dy &= \int_{B(0;1)} \rho^{-2} \Delta_z w(z) \rho^d dz \\ &= \rho^{d-2} \int_{B(0;1)} \Delta_z w(z) dz \\ &= \rho^{d-2} \int_{S(0;1)} \nabla_z w(z) \cdot z d\omega. \end{aligned}$$

We used change of variables, and integration by parts in the above computations.

So the measure dy is given by rho power d into dx in view of that and the equation that we have just derived Laplacian yg in terms of Laplacian zw what we get is this particular integral. Now we are going to do change of variable z = y – x by rho that domain of integration transforms to this b of 0, 1 and the integrant will be rho power -2 into Laplacian z and the dy the measure becomes rho power d dz.

So pulling the rho terms outside what I have is rho power d – 2 into integral over ball of radius 1 center 0 Laplacian at w. So now from here we get this by integration by paths or (()) (08:45) theorem. So we use change of variable or integration by paths in these computations.

(Refer Slide Time: 08:54)

Multiple integrals: Change of variables, Integration by parts (contd.)

In view of $\nabla_{\mathbf{y}} g(\mathbf{y}) = \rho^{-1} \nabla_{\mathbf{z}} w \left(\frac{\mathbf{y}-\mathbf{x}}{\rho} \right)$,
we have

$$\begin{aligned} \rho^{d-2} \int_{S(\mathbf{0};1)} \nabla_{\mathbf{z}} w(\mathbf{z}) \cdot \mathbf{z} \, d\omega &= \rho^{d-2} \int_{S(\mathbf{0};1)} \rho \nabla_{\mathbf{y}} g(\mathbf{x} + \rho \mathbf{z}) \cdot \mathbf{z} \, d\omega \\ &= \rho^{d-1} \int_{S(\mathbf{0};1)} \nabla_{\mathbf{y}} g(\mathbf{x} + \rho \mathbf{z}) \cdot \mathbf{z} \, d\omega \\ &= \rho^{d-1} \int_{S(\mathbf{0};1)} \frac{\partial}{\partial \rho} (g(\mathbf{x} + \rho \mathbf{z})) \, d\omega \\ &= \rho^{d-1} \frac{\partial}{\partial \rho} \int_{\|\nu\|=1} g(\mathbf{x} + \rho \nu) \, d\omega. \end{aligned}$$

Now we also had one relation for the gradient under change of variables so using that the last equation that we obtained on the previous slide can be simplified expressed in terms of g . So this integrand is precisely dou by dou rho of this quantity and dou by dou rho will come out of the integral now. So this is the expression that we have got.

(Refer Slide Time: 09:32)

Multiple integrals: Change of variables, Integration by parts (contd.)

Thus we proved

$$\int_{B(\mathbf{x};\rho)} \Delta_{\mathbf{y}} g(\mathbf{y}) \, d\mathbf{y} = \rho^{d-1} \frac{\partial}{\partial \rho} \int_{\|\nu\|=1} g(\mathbf{x} + \rho \nu) \, d\omega.$$

So this what we have proved integral of the Laplacian G over B of \mathbf{x} rho is given in terms of rho power $d - 1$ rho by dou rho del derivative of this quantity the integral on the unit sphere with center origin.

(Refer Slide Time: 09:53)

Spherical means and the Darboux formula

Now we are in the position to introduce spherical means and the Darboux formula.

(Refer Slide Time: 10:01)

Definition of Spherical means

Let $g : \mathbb{R}^d \rightarrow \mathbb{R}$ be a continuous function.

The spherical mean of g , denoted by $M_g(\mathbf{x}, \rho)$, is a function

$$M_g : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R} \\ (\mathbf{x}, \rho) \mapsto M_g(\mathbf{x}, \rho)$$

defined by

$$M_g(\mathbf{x}, \rho) := \frac{1}{|S(\mathbf{x}; \rho)|} \int_{S(\mathbf{x}; \rho)} g(\mathbf{y}) d\sigma,$$

where $d\sigma$ is the surface measure on the sphere $S(\mathbf{x}; \rho)$, and $|S(\mathbf{x}; \rho)|$ denotes the measure of $S(\mathbf{x}; \rho)$, which equals $\rho^{d-1} \omega_d$.

So take continuous function g defined on \mathbb{R}^d to \mathbb{R} let them continuous function. The spherical mean of g denoted by M_g M for mean we are talking about mean of the function g . Because later on we are going to deal with means of at least 3 functions 1 is means of the solution u and mean of the initial data ϕ and ψ that is why we introduce g here not to get any confusion later on. So M_g of \mathbf{x}, ρ it is a function defined on \mathbb{R}^d cross infinity taking values in \mathbb{R} .

So M_g of \mathbf{x}, ρ is defined by integral g over this sphere $S(\mathbf{x}; \rho)$ and divide with the measure of $S(\mathbf{x}; \rho)$ that is why it is called mean. And $d\sigma$ is surface measure on this sphere and what is

the measure of $S(x, \rho)$? That is precisely ρ^{d-1} into ω_d this we have already stated.

(Refer Slide Time: 11:12)

Spherical means are Spherical averages

The formula

$$M_g(\mathbf{x}, \rho) := \frac{1}{|S(\mathbf{x}, \rho)|} \int_{S(\mathbf{x}, \rho)} g(\mathbf{y}) d\sigma$$

integrates the function g over the sphere $S(\mathbf{x}, \rho)$ and compares it with the surface area of the sphere $|S(\mathbf{x}, \rho)|$. Thus Spherical means are averages of the function over spheres.

Spherical means mean spherical averages so this formula which defines spherical means is integrating the function g over this sphere and compares it with the surface area of this sphere. Recall how arithmetic means are defined if this is exactly similar so spherical means are averages of the function over spheres.

(Refer Slide Time: 11:39)

Question 1. Why are we considering Spherical means? Advantages?

Answer. Knowing all spherical means of a function is equivalent to knowing the function.

- Function can be retrieved from its spherical means.

Now we a question why are we considering spherical means? Are there any advantages to be done? Knowing all the spherical means of a function is same as or is equivalent to knowing the

function itself. And importantly function can be retrieved from its spherical means that is the idea.

(Refer Slide Time: 12:03)

Question 1. Why are we considering Spherical means? Advantages?

Answer. Knowing all spherical means of a function is equivalent to knowing the function.

- Function can be retrieved from its spherical means.

We will state more precisely results which say which asset function can be retrieved from spherical means we will do that.

(Refer Slide Time: 12:12)

Question 2. Are we complicating by introducing an additional variable ρ ?

Answer. Not at all.

- Once we fix x , spherical means are functions of only one variable, namely ρ .
- This will help us in reducing the Wave equation in d dimensions to an equation with a time variable and one more independent variable.

So now another question is are we complicating by introducing an additional variable rho? Not at all once we fix x the spherical means are functions of only one variable namely rho. So this will help us in reducing the wave equation in d dimensions to an equation with a time variable and one more independent variable we will see that.

(Refer Slide Time: 12:38)

$$\begin{aligned}
 \int_{S(\mathbf{x};\rho)} g(\mathbf{y}) d\sigma &= \int_{B(\mathbf{x};\rho)} \sum_{i=1}^d \frac{\partial}{\partial y_i} \left(g(\mathbf{y}) \frac{y_i - x_i}{\rho} \right) d\mathbf{y} \\
 &= \int_{B(\mathbf{0};1)} \sum_{i=1}^d \rho^{-1} \frac{\partial}{\partial z_i} (g(\mathbf{x} + \rho\mathbf{z}) z_i) \rho^d dz \\
 &= \rho^{d-1} \int_{B(\mathbf{0};1)} \sum_{i=1}^d \frac{\partial}{\partial z_i} (g(\mathbf{x} + \rho\mathbf{z}) z_i) dz \\
 &= \rho^{d-1} \int_{S(\mathbf{0};1)} \sum_{i=1}^d g(\mathbf{x} + \rho\mathbf{z}) z_i^2 d\omega \\
 &= \rho^{d-1} \int_{S(\mathbf{0};1)} g(\mathbf{x} + \rho\mathbf{z}) d\omega
 \end{aligned}$$

Let us look at this computation where we are integrating g over the sphere $S(\mathbf{x}, \rho)$ that by Green's theorem is equal to this. So please compute this quantity on the right hand side you will get the quantity on the left hand side. Now why, are we doing this we will see at the end of this computation and the reason for doing this? Now this we are now changing the variable where ball of \mathbf{x}, ρ becoming ball of $\mathbf{0}, 1$ and the measure, d by natural ρ power d dz and the derivative $\frac{\partial}{\partial y_i}$ is $\rho^{-1} \frac{\partial}{\partial z_i}$.

We have already established these facts so finally we have an integral on ball of $\mathbf{0}, 1$ now we will write this using once again integration by parts of Green's theorem and express this as an integral on the sphere $S(\mathbf{0}, 1)$. So we end up with this expression and if you notice this is does not depend on i so it can come out what I have summation $i = 1$ to d z_i^2 where is z ? z is on this sphere therefore $\|z\| = 1$ and summation $i = 1$ to d z_i^2 is 1 .

Therefore we get this expression so we have got integral on $S(\mathbf{x}, \rho)$ we have converted that to integral on $S(\mathbf{0}, 1)$ so we did change of variables in spheres.

(Refer Slide Time: 14:18)

$$\begin{aligned}
\int_{S(\mathbf{x};\rho)} g(\mathbf{y}) d\sigma &= \int_{B(\mathbf{x};\rho)} \sum_{i=1}^d \frac{\partial}{\partial y_i} \left(g(\mathbf{y}) \frac{y_i - x_i}{\rho} \right) d\mathbf{y} \\
&= \int_{B(\mathbf{0};1)} \sum_{i=1}^d \rho^{-1} \frac{\partial}{\partial z_i} (g(\mathbf{x} + \rho \mathbf{z}) z_i) \rho^d d\mathbf{z} \\
&= \rho^{d-1} \int_{B(\mathbf{0};1)} \sum_{i=1}^d \frac{\partial}{\partial z_i} (g(\mathbf{x} + \rho \mathbf{z}) z_i) d\mathbf{z} \\
&= \rho^{d-1} \int_{S(\mathbf{0};1)} \sum_{i=1}^d g(\mathbf{x} + \rho \mathbf{z}) z_i^2 d\omega \\
&= \rho^{d-1} \int_{S(\mathbf{0};1)} g(\mathbf{x} + \rho \mathbf{z}) d\omega
\end{aligned}$$

So in view of the computation on the previous slide what was it about? We are just answered it is something to do with change on variables on spheres. Usually we learnt change of variable theorem for open sets in \mathbb{R}^d so that means we know how to handle open sets in \mathbb{R}^d whereas $S_{\mathbf{x}, \rho}$ is not an open set in \mathbb{R}^d . So directly if you write this equal to the last lines there are questions and this; what is establishing that this is indeed true. So we can be here like yes I know how to do change the variables even for spheres.

(Refer Slide Time: 14:53)

Remark on Spherical means

In view of the computation on the previous slide (What was it about?), and since $|S(\mathbf{x}; \rho)| = \rho^{d-1} \omega_d$, we may write

$$\begin{aligned}
\frac{1}{|S(\mathbf{x}; \rho)|} \int_{S(\mathbf{x}; \rho)} g(\mathbf{y}) d\sigma &= \frac{\rho^{d-1}}{\rho^{d-1} \omega_d} \int_{S(\mathbf{0}; 1)} g(\mathbf{x} + \rho \mathbf{z}) d\omega \\
&= \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho \nu) d\omega.
\end{aligned}$$

In view of the definition of spherical means $M_g(\mathbf{x}, \rho)$, we get

$$M_g(\mathbf{x}, \rho) = \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho \nu) d\omega. \quad \square$$

So that is about it how this is the definition of M_g of \mathbf{x} , ρ now that we have alternate expression which is $\frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho \nu) d\omega$

1. So in view of the definition of the spherical means which is actually M_g equal to this now we have established is equal to this. So we have a new formula for M_g equal to this.

(Refer Slide Time: 15:32)

Spherical means $M_g(\mathbf{x}, \rho)$ was defined by

$$M_g(\mathbf{x}, \rho) := \frac{1}{|S(\mathbf{x}, \rho)|} \int_{S(\mathbf{x}, \rho)} g(\mathbf{y}) d\sigma.$$

We obtained

$$M_g(\mathbf{x}, \rho) = \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho\nu) d\omega.$$

Question. What is the advantage of the second formula over the first one?

Answer. Observe the domains of integration in these formulae.

So spherical means was defined by the formula $M_g = 1$ by measure of $S \times \rho$ by integral over $S \times \rho$ of $g(\mathbf{y}) d\sigma$ and we obtained another expression why are we doing this? What is that advantage of the second formula over the first one the answer is observed the domains of integration in these formulae. What is the domain here? $S \times \rho$; what is the domain here? Norm $\|\nu\| = 1$ what is this function M_g of \mathbf{x}, ρ so if I want to differentiate either with respect to $S \times \rho$ with respect to ρ here it is difficult.

Because the domain itself is varying with \mathbf{x} and ρ whereas in this expression it does not depend on \mathbf{x} it does not depend on ρ that is the advantage we have.

(Refer Slide Time: 16:23)

Lemma on Spherical means (LoSM)

Hypotheses

- Let $g : \mathbb{R}^d \rightarrow \mathbb{R}$ be a continuous function.
- Let $M_g : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R}$ be defined by

$$M_g(\mathbf{x}, \rho) := \frac{1}{|S(\mathbf{x}; \rho)|} \int_{S(\mathbf{x}; \rho)} g(\mathbf{y}) d\sigma.$$

So we have a lemma on spherical means we will often be using, we calling it LoSM lemma on spherical means hypotheses g is the continuous function and let M_g be define by this formula of the spherical means of g .

(Refer Slide Time: 16:41)

Lemma on Spherical means (LoSM)

Conclusions

- 1 M_g can be extended to the domain $\mathbb{R}^d \times \mathbb{R}$ such that $\rho \mapsto M_g(\mathbf{x}, \rho)$ is an even function, for each fixed $\mathbf{x} \in \mathbb{R}^d$.
- 2 Let $k \in \mathbb{N}$. If $g \in C^k(\mathbb{R}^d)$, then so is the function $(\mathbf{x}, \rho) \mapsto M_g(\mathbf{x}, \rho)$.
- 3 The function g can be **recovered** from $M_g(\mathbf{x}, \rho)$ in the following sense:

$$\lim_{\rho \rightarrow 0} M_g(\mathbf{x}, \rho) = g(\mathbf{x}) \text{ for all } \mathbf{x} \in \mathbb{R}^d.$$

Conclusion 1 sometime we call LoSM 1 what is it? M_g can be extended to the domain $\mathbb{R}^d \times \mathbb{R}$ such that for each fixed \mathbf{x} as the function of ρ it is an even function. Currently it has defined only for positive because we needed the ball to have a positive radius. So let k belongs to \mathbb{N} if g is the C^k function in \mathbb{R}^d then so is the function \mathbf{x}, ρ mapping to M_g of \mathbf{x}, ρ it is function defined on $\mathbb{R}^d \times \mathbb{R}$.

Note by 1 conclusion 1 we already extended the function M_g of x, ρ where ρ belonging to \mathbb{R} and the function g can be recovered from the spherical means this is the most important property. What do you mean by that? You take M_g of x, ρ and take limit as ρ goes to 0 you get g of x and this happens for every x .

(Refer Slide Time: 17:46)

Proof of Conclusion 1 (contd.)

The equation

$$M_g(\mathbf{x}, \rho) = \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} - \rho\nu) d\omega$$

suggests that the function M_g can be extended to the domain $\mathbb{R}^d \times (\mathbb{R} \setminus \{0\})$ such that

$\rho \mapsto M_g(\mathbf{x}, \rho)$ is an even function, for each fixed $\mathbf{x} \in \mathbb{R}^d$.

Setting $M_g(\mathbf{x}, 0) = g(\mathbf{x})$, the function $\rho \mapsto M_g(\mathbf{x}, \rho)$ is now meaningful for all $\rho \in \mathbb{R}$. □

Now let us prove conclusion 1 observe this equality holds why? Because the units sphere is invariant under the mapping ν going to $-\nu$ so, therefore these integrals are same therefore M_g which we know is equal to this is now also equal to this quantity. So in other words M_g as the function of ρ whether you put plus ρ or minus ρ it is a same that means the function is even. So we can use the same formula to extend M_g of x, ρ even for ρ negative.

So we can do this for ρ negative ρ positive we have started defining spherical means for ρ positive we have not extended for ρ negative what about 0? So 0 we just take it to $g(x)$ M_g of $x, 0 = g(x)$ this also consistent with the third assertion of this lemma then it is defined for all ρ . So just to summarize we have defined M_g of x, ρ for ρ positive then we observe that if repress ρ with minus ρ the integral does not change. Therefore we can extend M_g of x, ρ even for negative ρ and for ρ equal to 0 we define by M_g of $x, 0 = g(x)$.

(Refer Slide Time: 19:21)

Proof of Conclusion 2.

If $g \in C^k(\mathbb{R}^d)$, then from

$$M_g(\mathbf{x}, \rho) = \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho\nu) d\omega,$$

it follows that the function $(\mathbf{x}, \rho) \mapsto M_g(\mathbf{x}, \rho)$ belongs to $C^k(\mathbb{R}^d \times \mathbb{R})$. **How?**

So let us go to the proof of conclusion 2 if g is the C^k function in \mathbb{R}^d define an \mathbb{R}^d then from this formula M_g of \mathbf{x} $\rho = 1$ by ω_d integral over norm ν equal 1 g of $\mathbf{x} + \rho \nu$ $d\omega$. Notice that \mathbf{x} and ρ appears inside the argument of this function g therefore if $g \in C^k$ then M_g of \mathbf{x} ρ will be C^k also. So it follows that this function \mathbf{x} ρ going to M_g \mathbf{x} ρ C^k of \mathbb{R}^d cross \mathbb{R} how? We have to justify the interchange of derivative on the integration and there is an exercise in an answer.

(Refer Slide Time: 20:04)

Proof of Conclusion 3.

Conclusion 3 re-phrased. For each $\mathbf{x} \in \mathbb{R}^d$,

$$\lim_{\rho \rightarrow 0} \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho\nu) d\omega = g(\mathbf{x}).$$

Let $\varepsilon > 0$ be given. Let us estimate

$$\begin{aligned} \left| \frac{1}{\omega_d} \int_{\|\nu\|=1} g(\mathbf{x} + \rho\nu) d\omega - g(\mathbf{x}) \right| &= \left| \frac{1}{\omega_d} \int_{\|\nu\|=1} (g(\mathbf{x} + \rho\nu) - g(\mathbf{x})) d\omega \right| \\ &\leq \frac{1}{\omega_d} \int_{\|\nu\|=1} |g(\mathbf{x} + \rho\nu) - g(\mathbf{x})| d\omega \end{aligned}$$

Now proof of conclusion 3 let us refresh the conclusion this is limit ρ goes to 0 this is M_g of \mathbf{x} ρ . That is equal to $g(\mathbf{x})$ this is what we want to show so do you show this? Start estimating the difference between this quantity and $g(\mathbf{x})$ so let ε be given positive be given let us estimate

this quantity whose limit you want to find you want to show that limited $g(x)$ therefore estimate the distance. Now $g(x)$ can be written as $\frac{1}{\omega_d} \int_{\|v\|=1} g(x + \rho v) d\omega$ because ω_d is after all the measure of the set $\|v\|=1$.

Therefore we can do that of course g itself cannot depend on ρ so we can put it inside now we take the modulus inside the integral. So modulus of the integral is $(\int |f|)^2 \geq |\int f|^2$ (21:05) integral of modulus and we get this. Now this suggest something to be used the property of g here g is continuous at x . So therefore this can be made small as a result this can be made small and we achieve what we want to show that is the idea.

(Refer Slide Time: 21:27)

Proof of Conclusion 3.

Since g is continuous at x , there exists a $\delta > 0$ such that for every y with $\|y - x\| < \delta$,

$$|g(y) - g(x)| < \varepsilon.$$

Therefore, we have for $|\rho| < \delta$,

$$|g(x + \rho v) - g(x)| < \varepsilon.$$

Conclusion 3 follows from the estimate

$$\left| \frac{1}{\omega_d} \int_{\|v\|=1} g(x + \rho v) d\omega - g(x) \right| \leq \frac{1}{\omega_d} \int_{\|v\|=1} |g(x + \rho v) - g(x)| d\omega. \quad \square$$

Since g is continuous at x there is a delta whenever y is delta close to x $g(y) - g(x)$ is less than epsilon in modulus. Therefore we are not interested in arbitrary y but we are interested in y which is looking like $x + \rho v$ where v is having unit norm. So therefore for $|\rho| < \delta$ this becomes $|g(x + \rho v) - g(x)| < \varepsilon$. So now conclusion 3 follows from this estimate because this is less than epsilon.

So the RHC is less than or equal to epsilon by $\omega_d \int_{\|v\|=1} |g(x + \rho v) - g(x)| d\omega$ which will give you ω_d . So $\omega_d - \omega_d$ cancels and we get epsilon so the conclusion 3 follows.

(Refer Slide Time: 22:27)

Lemma: Darboux formula

For $g \in C^2(\mathbb{R}^d)$, the Darboux formula holds:

$$\left(\frac{\partial^2}{\partial \rho^2} + \frac{d-1}{\rho} \frac{\partial}{\partial \rho} \right) M_g(\mathbf{x}, \rho) = \Delta_{\mathbf{x}} M_g(\mathbf{x}, \rho),$$

where $\Delta_{\mathbf{x}}$ stands for the Laplacian operator in the variables x_1, x_2, \dots, x_d , i.e.,

$$\Delta_{\mathbf{x}} = \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \dots + \frac{\partial^2}{\partial x_d^2}.$$

Now let us prove Darboux lemma for g in C^2 of \mathbb{R}^d the Darboux formula holds what is the Darboux formula? It is this Laplacian in the x variable of M_g of x rho is this quantity. So the Laplacian $\Delta_{\mathbf{x}}$ stands for Laplacian operator the variables x_1 up to x_d which is here. Actually if you looking at the Laplacian equation we have not yet looked at Laplacian equation and you want to look at solution which depends on only on the radius R then that you end up with this operator.

So this is actually the radial Laplacian other angular parts are ignored I am not looking at solution which depends on angles therefore only the radial part this is that.

(Refer Slide Time: 23 27)

Proof of Darboux formula (contd.)

Differentiating both sides of the equation

$$\rho^{d-1} \frac{\partial}{\partial \rho} M_g(\mathbf{x}, \rho) = \frac{1}{\omega_d} \int_0^\rho r^{d-1} \Delta_{\mathbf{x}} \left(\int_{\|\nu\|=1} g(\mathbf{x} + r\nu) d\omega \right) dr.$$

w.r.t. ρ , we get

$$\frac{\partial}{\partial \rho} \left(\rho^{d-1} \frac{\partial}{\partial \rho} M_g(\mathbf{x}, \rho) \right) = \rho^{d-1} \Delta_{\mathbf{x}} (M_g(\mathbf{x}, \rho)).$$

Recall that we have proved this Laplacian on d of x ρ is given by this quantity this we have already proved in the beginning. So this quantity is actually this with a ω_{d-1} by ω_d missing you put ω_d so you get this multiply both sides with $1/\omega_d$ you have this equal. Now express this integral on the ball using polar coordinates R and $d\omega$ so you have this expression.

Now differentiate both sides with respect to ρ so LHS is simply this and RHS by fundamental theorem of calculus is the integrand evaluated at ρ which is this.

(Refer Slide Time: 24:23)

Proof of Darboux formula (contd.)

$$\frac{\partial}{\partial \rho} \left(\rho^{d-1} \frac{\partial}{\partial \rho} M_g(\mathbf{x}, \rho) \right) = \rho^{d-1} \Delta_{\mathbf{x}} (M_g(\mathbf{x}, \rho)).$$

Computing the derivative on the LHS of the above equation yields

$$(d-1)\rho^{d-2} \frac{\partial}{\partial \rho} M_g(\mathbf{x}, \rho) + \rho^{d-1} \frac{\partial^2}{\partial \rho^2} M_g(\mathbf{x}, \rho) = \rho^{d-1} \Delta_{\mathbf{x}} (M_g(\mathbf{x}, \rho)).$$

Cancelling the factor ρ^{d-1} yields the **Darboux formula**.

Now we can expand this derivatives which are here and we get this now if you cancel ρ^{d-1} on both LHS and RHS what we get is precisely the Darboux formula.

(Refer Slide Time: 24:43)

Reduction to an equivalent Cauchy problem

Now let us reduce the Cauchy problem for the wave equation to an equivalent Cauchy problem.

(Refer Slide Time: 24:51)

Equivalent Cauchy problem

Let $u \in C^2(\mathbb{R}^d \times \mathbb{R})$ be a solution to the Cauchy problem for d dimensional wave equation.

For each fixed $t \in \mathbb{R}, x \in \mathbb{R}^d$, define

$$M_u(x, t, \rho) := \frac{1}{\omega_d} \int_{\|\nu\|=1} u(x + \rho\nu, t) d\omega.$$

Apply Laplacian operator on both sides of the above equation.

So for that we have to introduce spherical means associated to the solution or the unknown function u . So let u be a C^2 function be a solution to the Cauchy problem for d dimensional wave equation for each fixed t and x define the spherical means. A $M_u(x, t, \rho)$ earlier when we were dealing with spherical means there is no variable called t therefore it was missing we had x and ρ but now we have to include that because we are trying to solve wave equation now.

So $M_u(x, t, \rho)$ is exactly as before now apply Laplacian on both sides of the above equation what do you get?

(Refer Slide Time: 25:37)

Equivalent Cauchy problem (contd.)

Apply Laplacian operator on both sides of the equation

$$M_u(\mathbf{x}, t, \rho) = \frac{1}{\omega_d} \int_{\|\nu\|=1} u(\mathbf{x} + \rho\nu, t) d\omega.$$

we obtain for each fixed $t \in \mathbb{R}$,

$$\begin{aligned} \Delta_{\mathbf{x}} M_u(\mathbf{x}, t, \rho) &= \frac{1}{\omega_d} \int_{\|\nu\|=1} \Delta_{\mathbf{x}} u(\mathbf{x} + \rho\nu, t) d\omega \\ &= \frac{1}{c^2 \omega_d} \int_{\|\nu\|=1} \frac{\partial^2}{\partial t^2} u(\mathbf{x} + \rho\nu, t) d\omega \\ &= \frac{1}{c^2} \frac{\partial^2}{\partial t^2} M_u(\mathbf{x}, t, \rho) \end{aligned}$$

What we get is? This is just an applying Laplacian and writing so we need to really do here the Laplacian has gone inside here that is the change. Now u is the solution right so Laplacian x u is u tt by c square because u a solution to the homogenous wave equation so then we have this. Now bring dou 2 by dou t square outside and we have this so what we have is Laplacian Mu is 1 by c square dou 2 by dou t square Mu.

(Refer Slide Time: 26:25)

Lemma Equivalent Cauchy problems

The following statements concerning a function $u \in C^2(\mathbb{R}^d \times \mathbb{R})$ are equivalent.

- 1 u is a solution to the Cauchy problem for d dimensional wave equation.
- 2 The function $M_u(\mathbf{x}, t, \rho)$ solves the following Cauchy problem

$$\begin{aligned} \frac{\partial^2}{\partial t^2} M_u(\mathbf{x}, t, \rho) &= c^2 \left(\frac{\partial^2}{\partial \rho^2} + \frac{d-1}{\rho} \frac{\partial}{\partial \rho} \right) M_u(\mathbf{x}, t, \rho), & \rho \in \mathbb{R}, t > 0, \\ M_u(\mathbf{x}, 0, \rho) &= M_\varphi(\mathbf{x}, \rho), & \rho \in \mathbb{R}, \\ \frac{\partial M_u}{\partial t}(\mathbf{x}, 0, \rho) &= M_\psi(\mathbf{x}, \rho), & \rho \in \mathbb{R}. \end{aligned}$$

Now we have this statement about the equivalent Cauchy problems so the following statement concerning a function u which is C2 of Rd cross R, are equivalent what are those? u is a solution to the Cauchy problem for d dimensional wave equation and that is same as saying dou 2 by dou

t square of Mu is c square into this operator acting on Mu and of course the initial data for Mu and dou by dou t of Nu we will prove this. Very simple proof we have done all the computation I will just indicate how to go about this proof.

(Refer Slide Time: 27:07)

Proof of Lemma

- Statement 2 follows from Statement 1 by direct computation using the definition of $M_\mu(x, t, \rho)$, in view of the computations immediately preceding the statement of this Lemma, and Darboux formula.
- Statement 1 follows from Statement 2 in view of Darboux formula, and **Conclusion 3 of Lemma on Spherical means (LoSM)**. You are urged to fill in the details of the proof. □

So statement 2 follows from statement 1 but direct computation using the definition of Mu we have done all the computation all the computations immediately preceding the statement of this lemma and Darboux formula. Statement 1 follows from state 2 in view of the above formula and conclusion 3 of LoSM that is the function can be retrieved from its spherical means. So you are asked to fill in the details of the proof very simple details you have to just write down a few lines. All the computations are already there and I have given you how to go about here.

(Refer Slide Time: 27:49)

Summary

- 1 Introduced **Spherical means** for a continuous function.
 - Found that pointwise values of the function may be obtained from the knowledge of all spherical means.
- 2 Cauchy problem for wave equation in d space dimensions has an equivalent formulation involving only two independent variables t, ρ .
 - Thus 'reducing the complexity' of the Cauchy problem.
- 3 In next few lectures, Cauchy problems for $d = 3$ will be solved using the equivalent formulation. Further, solution to the Cauchy problem for $d = 2$ will be obtained using that of $d = 3$.

So let us summarize what we did in this lecture we have introduced spherical means for a continuous function found that point wise values of the function may be obtained from the knowledge of all spherical means. Cauchy problem for wave equation in d space dimensions has a equivalent formulation involving only 2 dependent variables. Thus reducing the complexity of the problem in the few lectures Cauchy problem for $d = 3$ will be solved using the equivalent formulation.

Further solution to the Cauchy problem for the $d = 2$ will be obtained using the solution that we get for $d = 3$ case.
