Lecture – 5.3
Qualitative Analysis of Wave Equation
Causality Principle, Finite Speed of Propagation

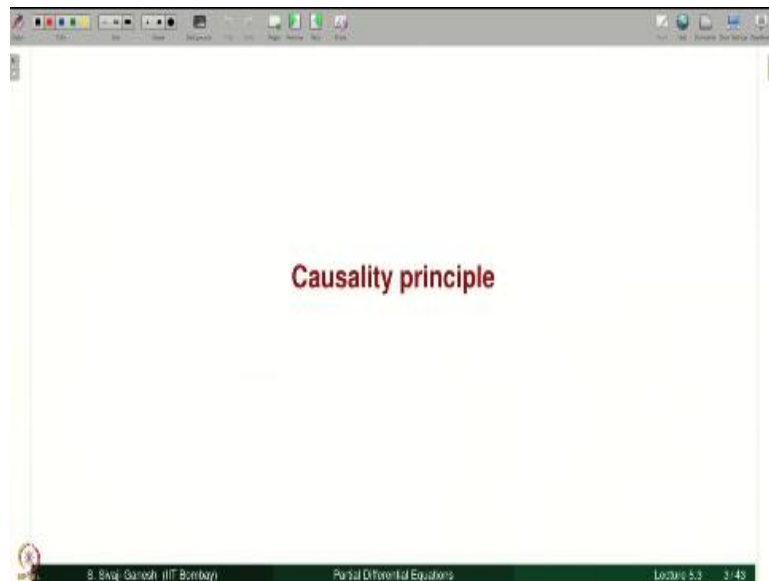

Let us continue our qualitative study of the wave equation. And today, we are going to look at what is called a causality principle and finite speed of propagation, a property which is exclusive to hyperbolic equations. We will look at them 2 examples.

(Refer Slide Time: 00:35)

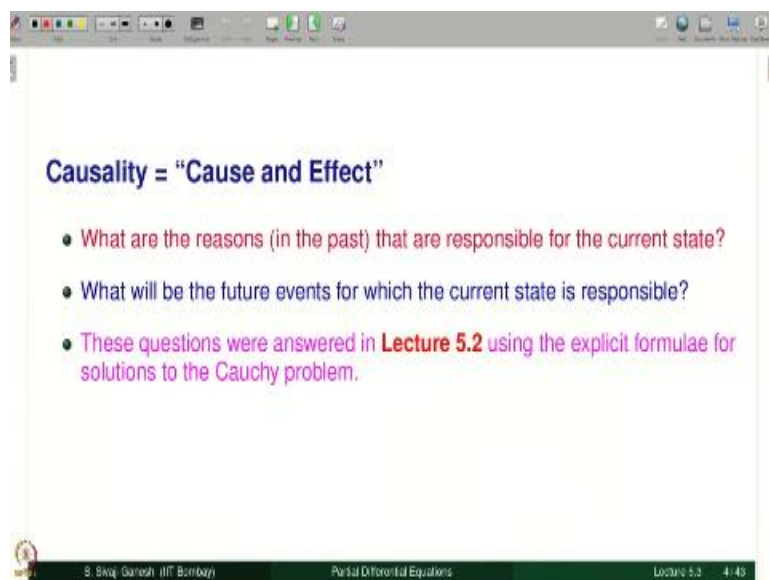

These are the 2 sides of domain of dependence and domain of influence of that concepts. So, causality principle, finite speed of propagation.

(Refer Slide Time: 00:45)

(Refer Slide Time: 00:46)

Causality means cause and effect. What are the reasons in the past that are responsible for the current state? What will be the future events for which the current state is responsible for our influences? These questions were answered in lecture 5.2 using the explicit formulae for solutions to the Cauchy problem.

(Refer Slide Time: 01:09)

Causality = "Cause and Effect" (contd.)

- In this lecture, we attempt to answer the same questions without using the formulae for solutions.
 - This justifies the use of the word "qualitative analysis" in the title of this chapter.
- The analysis presented in this lecture is a typical illustration of an *a priori* analysis.
 - Conclusions can be drawn on solutions despite zero knowledge on their existence.
- In this discussion we switch-off the nonhomogeneous term in the wave equation for the reasons explained in **Lecture 5.2**

8. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 8/48

In this lecture, we attempt to answer the same questions without using the formula for solutions. This kind of justifies the use of the word qualitative analysis in the title of this chapter, because we are not using any quantitative formula for the solutions. The analysis presented in this lecture is a typical illustration of an a priori analysis. A priori means done before. Conclusions can be drawn on solutions. Despite 0 knowledge on their existence.

We may not be even knowing whether solution exists or not, still we can conclude certain things about the solution of course, if they exist that we do not know. So, in this discussion, once again like in lecture 5.2, we are going to switch off the nonhomogeneous term and we have already explained the reasons for that in lecture 5.2.

(Refer Slide Time: 02:10)

Theorem

Hypotheses

Let $u : \mathbb{R}^d \times (0, \infty) \rightarrow \mathbb{R}$ be a classical solution of the Cauchy problem for a homogeneous wave equation, i.e., u is a solution of

$$\square_d u \equiv u_{tt} - c^2 (u_{x_1 x_1} + u_{x_2 x_2} + \dots + u_{x_d x_d}) = 0, \quad \mathbf{x} \in \mathbb{R}^d, t > 0.$$

$$u(\mathbf{x}, 0) = \varphi(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d.$$

$$u_t(\mathbf{x}, 0) = \psi(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d.$$

8. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 8/48

So, let us state in the form of a theorem, the hypothesis is let you from \mathbb{R}^d cross 0 infinity to \mathbb{R} be a classical solution or the Cauchy problem for homogeneous wave equation that is this is a problem where ϕ and ψ are given of course, in the Cauchy problem and u is a solution to this Cauchy.

(Refer Slide Time: 02:32)

Theorem (contd.)

Conclusion

For $(x_0, t_0) \in \mathbb{R}^d \times (0, \infty)$, the value of $u(x_0, t_0)$ depends only on the values of ϕ and ψ in the closure of the ball $B(x_0, ct_0)$.

Recall that $B(x_0, ct_0)$ is the open ball with center at $x_0 \in \mathbb{R}^d$, and having a radius of ct_0 , lying in \mathbb{R}^d .

Handwritten notes:
 $B(x_0, ct_0) = \{y \in \mathbb{R}^d / \|y - x_0\| < ct_0\}$
 $B[x_0, ct_0] = \{y \in \mathbb{R}^d / \|y - x_0\| \leq ct_0\}$

9. Bhaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 7/48

Conclusion: for x_0, t_0 a point in the space time, the value of u of x_0, t_0 depends only on the values of ϕ and ψ in the closure of this open ball with centre x_0 and radius ct_0 . Closure of this open ball is nothing but the closed ball with the same radius and centre. Recall that B of x_0, ct_0 is the open ball with centre at x_0 in \mathbb{R}^d and having a radius of ct_0 lying in \mathbb{R}^d . So, maybe, we just briefly write what that is.

So, those elements in \mathbb{R}^d whose distance the Euclidean distance from the point x is less than ct_0 . This is the open ball and the closed unit ball, we do not use but then let me introduce good notation is that those elements in \mathbb{R}^d such that $y - x$ is less than or equal to ct_0 .

(Refer Slide Time: 03:53)

Proof of Theorem

- The theorem follows immediately from the formulae for solutions to the Cauchy problem, namely, d'Alembert formula ($d = 1$), Poisson-Kirchhoff formulae ($d = 2, 3$). This was done in Lecture 5.2.
- A direct proof is presented in this lecture without using the explicit formulae for solutions.
- We prove the theorem for $d = 1$ only.
- For $d = 2, 3$, the arguments in the proof are similar with obvious modifications.

8. Saq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 8:48

Proof of this theorem: it follows immediately from the formula for a solution to the Cauchy problem namely, d'Alembert formula for $d = 1$, Poisson-Kirchhoff formula for $d = 2$ and 3 . This was done in lecture 5.2. A direct proof is presented in this lecture without using the explicit formula for solutions. Of course, we are to use something that maybe some experience. We prove the theorem for $d = 1$ only.

Why is that? Because a proof for $d = 2$ and 3 are similar, but for the obvious modification that needs to be done to the proof of $d = 1$ to avoid a lot of repetition. We do not do the proof for $d = 2, 3$, but mentioned one important inequality there and how that can be derived, just the idea we will present.

(Refer Slide Time: 04:48)

Proof of causality principle for $d = 1$

8. Saq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 8:48

(Refer Slide Time: 04:51)

Proof of Theorem (contd.)

- Multiply the wave equation $u_{tt} - c^2 u_{xx} = 0$ with u_t . Observe that

$$0 = (u_{tt} - c^2 u_{xx}) u_t$$

$$= \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right)_t - c^2 (u_t u_x)_x$$
- Thus,

$$(\partial_x, \partial_t) \cdot \left(-c^2 u_t u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) = 0.$$

Integrating the last equation on the trapezium-region F ,

$$\int_F (\partial_x, \partial_t) \cdot \left(-c^2 u_t u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) dx dt = 0.$$

8. Bhaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 12/45

So, multiply the wave equation, this is a trick; the wave equation, you have to multiply with u_t , you get this and reorganize the terms, you get this. If you expand this, it will reduce to this. Now, this is in a good shape because here derivatives u_t into u_t is there; u_x into u_t is there whereas here some t derivative of some quantity, x derivative of some quantities is there, It is like the divergence theorem; we are in a good shape to apply divergence theorem.

Therefore, this is a good arrangement. So, in fact, when you see the divergence with x and t here of this quantity is 0. That is precisely this equation; this equals 0 means this. Now, integrate this equation on the trapezium region that we have indicated on the previous slide, you get this. Now, we are ready to do integration by parts or apply Greens theorem and divergence will be converted to something else.

(Refer Slide Time: 07:38)

Proof of Theorem (contd.)

$$\int_F (\partial_x, \partial_t) \cdot \left(-c^2 u_t u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) dx dt = 0$$

Using integration by parts formula (or divergence theorem) in the last equation, we get

$$0 = \int_F (\partial_x, \partial_t) \cdot \left(-c^2 u_t u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) = \int_{\partial F} \left(-c^2 u_t u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \cdot \mathbf{n} d\sigma$$

where \mathbf{n} is the unit outward normal to the boundary of F .

8. Bhaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 13/45

So, what we get is that this divergence of course is equal to 0 is now convert into an integral on the boundary of F . F is the triangle trapezium region; boundary of F is actually a trapezium and that this becomes the integrand dot n $d\sigma$; n is the normal outward unit normal to the points of boundary of F . Of course, that varies from point to point on the boundary of F .

(Refer Slide Time: 08:10)

Proof of Theorem (contd.)

The boundary of the trapezium F consists of four lines. They are

- The base of the trapezium, denoted by B , given by the equation $t = 0$.
- A part of the characteristic, denoted by K_1 , given by the equation $x + ct = x_0 + ct_0$.
- The upper part of the trapezium, denoted by T , given by the equation $t = T$.
- A part of the characteristic, denoted by K_2 , given by the equation $x - ct = x_0 - ct_0$.

So, the boundary of the trapezium consists of 4 lines actually the boundary of the trapezium region is a trapezium itself, it consists of 4 lines; they are the base of the trapezium denoted by B given by the equation $t = 0$; a part of the characteristic denoted by K_1 given by the equation $x + ct = x_0 + ct_0$; upper part of the trapezium denoted by T for top given by the equation $t = T$; and a part of the characteristic denoted by K_2 .

Remember, this is a point x_0, t_0 ; then we have drawn this. So, this is $x - x_0 - ct_0, x_0 + ct_0$, then we took this part. So, this equation for this is $t = T$. So, this, we are calling a B for base; this is K_1 ; T for top on K_2 . The integral is now on this, these lines. So, we need to determine what is the normal to each of these sides.

(Refer Slide Time: 09:24)

Proof of Theorem (contd.)

- The base of the trapezium, denoted by B . The outward unit normal to B is given by

$$\mathbf{n} = (0, -1)$$
- The upper part of the trapezium, denoted by T . The outward unit normal to T is given by

$$\mathbf{n} = (0, 1)$$

S. Bag, Sanehi (IIT Bombay) Partial Differential Equations Lecture 5.3 15/48

So, base of a trapezium outward unit normal is $0 - 1$; top unit outward normal is $0, 1$. So, this is the base; this is in the direction of negativity T axis, because this is x axis; this is t axis positive t axis direction, so this is in the negative direction so, $0 - 1$ and here, the top normal is in this direction, outward unit normal. It is in the direction of the positive t axis, so $0, 1$.

(Refer Slide Time: 10:09)

Proof of Theorem (contd.)

- A part of the characteristic, denoted by K_1 . The outward unit normal to K_1 is given by

$$\mathbf{n} = \frac{1}{\sqrt{1+c^2}}(1, c)$$
- A part of the characteristic, denoted by K_2 . The outward unit normal to K_2 is given by

$$\mathbf{n} = \frac{1}{\sqrt{1+c^2}}(-1, c)$$

S. Bag, Sanehi (IIT Bombay) Partial Differential Equations Lecture 5.3 15/48

Then we have the sides of the trapezium which is K_1 and K_2 at this point because K_1 itself is a straight line; it is very easy; it is constant on the direction is the same on all the points on K_1 . Similarly, the outward unit normal is in this direction and that is constant for all points on K_2 , therefore, the life is simpler.

(Refer Slide Time: 10:40)

Proof of Theorem (contd.)

$$0 = \int_F (\partial_x, \partial_t) \cdot \left(-c^2 u_x u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) = \int_{\partial F} \left(-c^2 u_x u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \cdot \mathbf{n} \, d\sigma$$

becomes

$$0 = \int_{\partial F} \left(-c^2 u_x u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \cdot \mathbf{n} \, d\sigma = \int_{B \cup K_1 \cup T \cup K_2} \left(-c^2 u_x u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \cdot \mathbf{n} \, d\sigma.$$

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 9.3 17/45

So, this integral on the boundary now, we can split into 4 parts which is B union K 1 union t union K 2.

(Refer Slide Time: 10:52)

Proof of Theorem (contd.)

Thus we get

$$0 = \int_{\partial F} \left(-c^2 u_x u_x, \frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \cdot \mathbf{n} \, d\sigma$$

$$= - \int_B \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \, d\sigma + \int_{K_1} \frac{-c^2 u_x u_x + \frac{c^2}{2} u_t^2 + \frac{c^2}{2} u_x^2}{\sqrt{1+c^2}} \, d\sigma$$

$$+ \int_T \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) \, d\sigma + \int_{K_2} \frac{c^2 u_x u_x + \frac{c^2}{2} u_t^2 + \frac{c^2}{2} u_x^2}{\sqrt{1+c^2}} \, d\sigma.$$

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 9.3 18/45

So, on B, we have applied what is a normal similarly on K 1, K 2 on t, we have used the formula for the normal that we written down on the previous slide we get this expression. So, some of these 4 terms is 0.

(Refer Slide Time: 11:08)

Proof of Theorem (contd.)

Observe that

$$\int_{K_1} \frac{-c^2 u_t u_x + \frac{c}{2} u_t^2 + \frac{c}{2} u_x^2}{\sqrt{1+c^2}} d\sigma = \frac{c}{2\sqrt{1+c^2}} \int_{K_1} (u_t - cu_x)^2 d\sigma \geq 0,$$

and

$$\int_{K_2} \frac{c^2 u_t u_x + \frac{c}{2} u_t^2 + \frac{c}{2} u_x^2}{\sqrt{1+c^2}} d\sigma = \frac{c}{2\sqrt{1+c^2}} \int_{K_2} (u_t + cu_x)^2 d\sigma \geq 0.$$

S. Singh, IIT Bombay Partial Differential Equations Lecture 9.3 13/45

Now, we do a trick; the integral and K_1 can be expressed like this and these an integral on K_1 of some non-negative quantity because of the presence of the square. These always greater than or equal to 0 and hence, this integral is greater than or equal to 0 that is the property of $d\sigma$. Non-negative functions, integral will be non-negative, similarly, here. Remember, this $d\sigma$ is nothing but the measure on the boundary which is coming from the domain trapezium.

So, this has all the nice properties. If you integrate a non-negative function, integral will be non-negative. So, the integral or K_1 and K_2 both of them are non-negative numbers.

(Refer Slide Time: 11:55)

Proof of Theorem (contd.)

From

$$-\int_B \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) d\sigma + \int_{K_1} \frac{-c^2 u_t u_x + \frac{c}{2} u_t^2 + \frac{c}{2} u_x^2}{\sqrt{1+c^2}} d\sigma + \int_T \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) d\sigma + \int_{K_2} \frac{c^2 u_t u_x + \frac{c}{2} u_t^2 + \frac{c}{2} u_x^2}{\sqrt{1+c^2}} d\sigma = 0,$$

we conclude that

$$\int_T \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) d\sigma \leq \int_B \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) d\sigma.$$

This inequality is known as **domain of dependence inequality**.

S. Singh, IIT Bombay Partial Differential Equations Lecture 9.3 27/45

So, here, I have some 4 quantities in that sum of 2 of them is non-negative. So, what can I say about the sum of the other 2? It should be non-positive that means that these 2 terms together

is less than or equal to 0 which means, I have the integral of this quantity on the top is less than or equal to integral of this quantity on the bottom. If you notice from this inequality, if u is 0 on the bottom, u and u_t are 0 on the bottom, then the zero, then there will be 0 on the top also.

This is the one which gives us uniqueness of solutions as we are going to see on the next slides. So, this inequality is called domain of dependence inequality that means, on the trapezium that on the top portion the integral is less than or equal to integral on the bottom portion.

(Refer Slide Time: 12:50)

Proof of Theorem (contd.)

- Let u and v be solutions of the Cauchy problem.
- Let us denote by w the difference of u and v i.e., $w := u - v$.
- Note that w solves the wave equation (due to linearity of the wave equation), and the Cauchy data satisfied by the function w are zero functions, as both u and v are solutions of the same Cauchy problem.
- Thus $w(x, 0) = 0 = w_t(x, 0)$ on B .

S. Bhaq, Saresh (IIT Bombay) Partial Differential Equations Lecture 6.3 21/48

So, let u and v be solutions of the Cauchy problem; define w by the difference u and v that is w equal $u - v$. Note that that w solves a wave equation due to linearity of the wave equation, of course and the Cauchy data will be 0 because both u and v are solutions to the same Cauchy problem. Therefore, both u and v will satisfy the same Cauchy data and hence, the difference will be satisfying the 0 Cauchy data. Therefore, w of $x, 0$ is 0 and w_t of $x, 0$ is 0 on the bottom.

(Refer Slide Time: 13:27)

Proof of Theorem (contd.)

- As a consequence of the domain of dependence inequality, we get

$$\int_T \left(\frac{1}{2} w_t^2 + \frac{c^2}{2} w_x^2 \right) d\sigma \leq 0.$$

- As a result, $w_t(x, T) = w_x(x, T) = 0$. Since $T < t_0$ is arbitrary, we conclude that

$$w_t(x, t) = w_x(x, t) = 0$$

for every (x, t) belonging to the characteristic triangle.

- This implies that w is a constant function, and since $w = 0$ on B , it follows that w is the zero function inside the characteristic triangle.

8. Shaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 9.3 23/43

Now, we can apply the domain of dependency inequality and conclude that we have this; right hand side has become 0; right hand side was the same integral on B that is 0 because on B, both w_t and w_x are 0. Therefore, this is what we have, but if you look at this already non-negative quantity and we are saying there is less than or equal to 0, so, this is always greater than or equal to 0, therefore, the only possibility is that the integrand is 0 which means w_t at what point, x, T and w_x at the point x, T is 0.

Now, T is arbitrary chosen $T < t_0$. Therefore, we get w_t of x, t and w_x of x, t is 0 for every x, t belonging to the characteristic triangle. This implies that w is a constant function but w is already 0 on B , therefore, it must be 0 everywhere. w is 0 everywhere same as saying u is equal to v everywhere in the characteristic triangle.

(Refer Slide Time: 14:37)

Proof of Theorem (contd.)

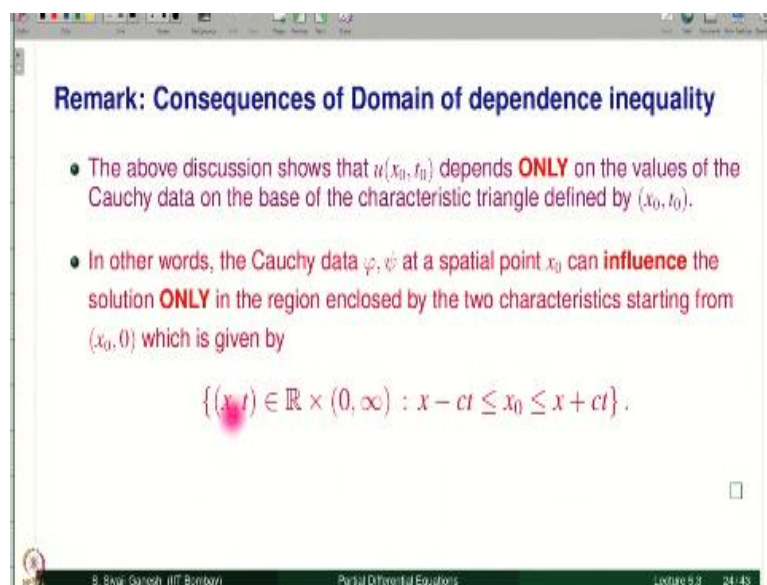

- Proved on last slide: w is the zero function inside the characteristic triangle.
- In particular, $u(x_0, t_0) = v(x_0, t_0)$.
- This finishes proof of the theorem.
- This is another proof of uniqueness of solutions to the Cauchy problem. We will see one more proof using the energy method.

8. Shaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 9.3 23/43

Therefore, the solution is the same; u at x_0, t_0 will be same as v at x_0, t_0 . So, proved on the last slide w is a 0 function inside the characteristic triangle. In particular, u of $x_0 = v$ of x_0, t_0 . This finishes the proof of the theorem. This is another proof of uniqueness of solutions to the Cauchy problem. We already gave one proof of uniqueness earlier. Now, this is another proof of uniqueness of solutions.

One more proof, we are going to see using the energy method; pretty much the actors in that energy method, we have already seen in the domain of dependence inequality. We will do that in the forthcoming lectures.

(Refer Slide Time: 15:24)

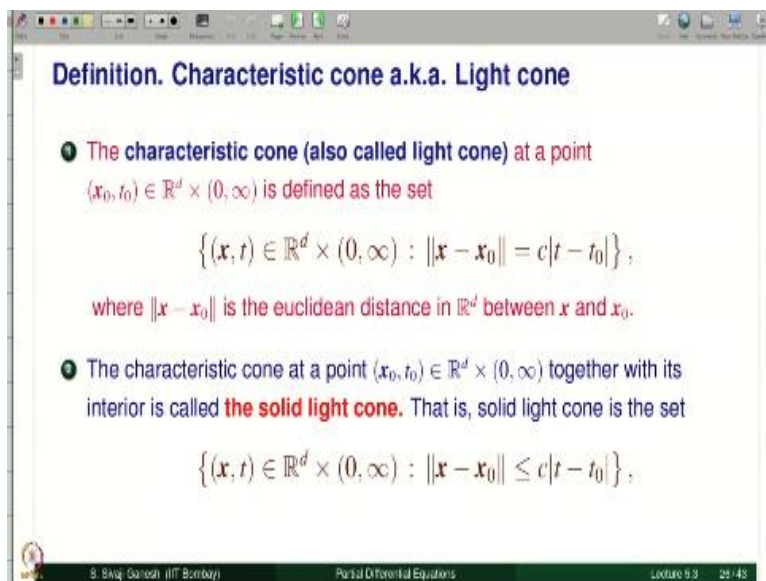

Consequences of domain of dependency inequality: the above discussion shows that u of x_0, t_0 depends only on the values of the Cauchy data on the base of the characteristic triangle defined by x_0, t_0 namely, the interval on the x axis $x_0 - ct_0, x_0 + ct_0$. In other words, the Cauchy data ϕ, ψ at a spatial point x_0 can influence the solution only in the region enclosed by the 2 characteristics starting from $x_0, 0$ on the x axis which is given by x, t in the space time domain such that $x - ct$ is less than or equal to x_0 and $x + ct$ is greater than or equal to x_0 .

(Refer Slide Time: 16:17)

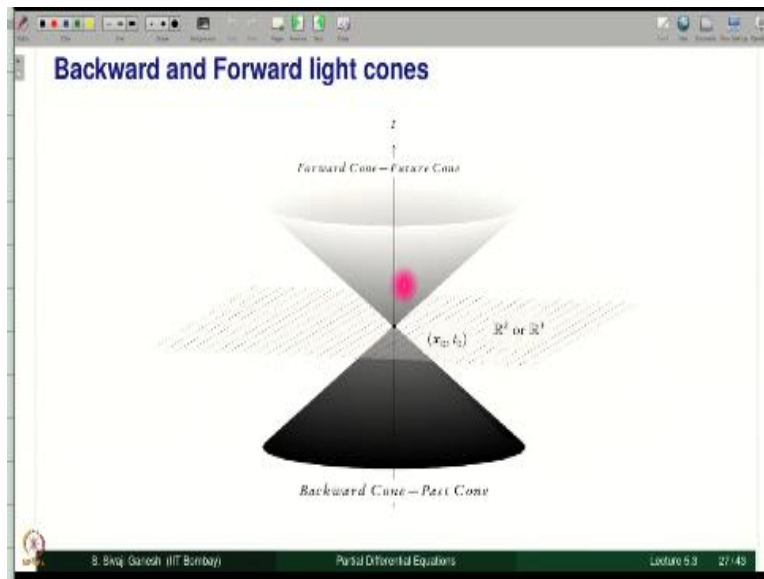

Let us look at the causality principle for d greater than or equal to 2 on characteristic cone.
What is the characteristic cone?

(Refer Slide Time: 16:24)

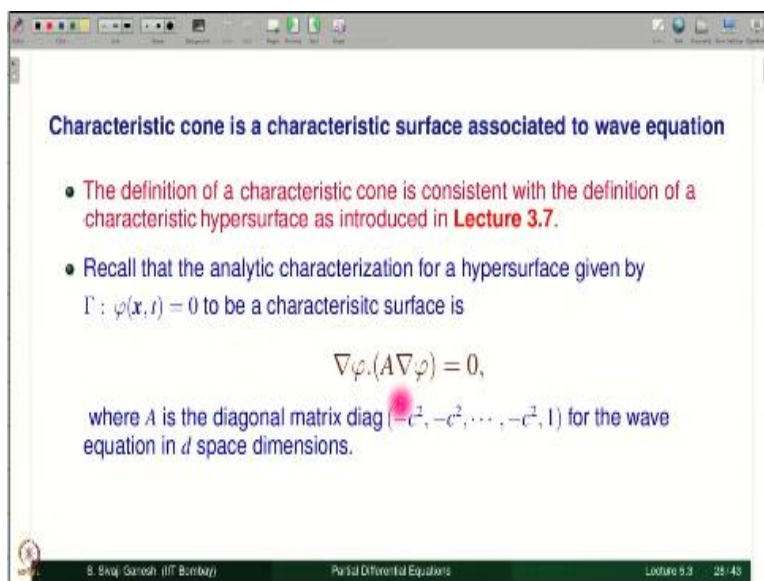

The characteristic cone also called light cone at a point x_0, t_0 in space time is defined as the set x, t in $\mathbb{R}^d \times (0, \infty)$ such that $\|x - x_0\| = c|t - t_0|$ where $\|x - x_0\|$ is a Euclidean distance in \mathbb{R}^d between x and x_0 . The characteristic cone at the point x_0, t_0 together with its interior, this is only the surface. This is with the interior. We are considering now that is called solid light cone that is the solid light cone is this such.

(Refer Slide Time: 17:17)

So, this is the picture. This, you can imagine \mathbb{R}^2 or \mathbb{R}^3 . It is easy to imagine \mathbb{R}^2 or \mathbb{R}^3 ; you cannot really imagine because the picture will be in 4 dimensions, but imagine this is \mathbb{R}^2 , then this is what is called forward cone or future cone. This is the backward cone or past cone. This is what x which is $x \neq 0, t = 0$.

(Refer Slide Time: 17:38)

So, the definition of a characteristic cone is consistent with the definition of a characteristic hypersurface which we have introduced in lecture 3.7. Recall that the analytic characterization for a hypersurface given by $\varphi(x, t) = 0$ to be a characteristic surface is $\text{grad } \varphi \cdot A \text{ grad } \varphi = 0$, where A is the diagonal matrix; $-c^2, -c^2, \dots, -c^2, 1$, further wave equation and d space dimensions.

(Refer Slide Time: 18:11)

Characteristic cone is a characteristic surface associated to wave equation (contd.)

- The equation

$$\nabla\varphi.(A\nabla\varphi) = 0$$

takes the form

$$\varphi_t^2 - c^2(\varphi_{x_1}^2 + \varphi_{x_2}^2 + \dots + \varphi_{x_n}^2) = 0.$$

- Note that $\varphi(x, t) = c^2(t - t_0)^2 - \|x - x_0\|^2$ is a solution of the last equation, and $\varphi(x, t) = 0$ is nothing but the characteristic cone through the point (x_0, t_0) .

© Saq. Ganesh IIT Bombay Partial Differential Equations Lecture 9.3 20/45

So, this equation takes this form when we expand this gradient is in x t. And what is A? It is a diagonal matrix described on the last slide. So, when we do that, we get this expression. It is phi t square – c square into norm grad phi square = 0; so, this equation is nothing but phi t square – c square mod grad phi square = 0 or we can put norm grad c square if you want or phi t is equal to plus or minus c mod grad phi.

Note that this function which is here is a solution to the last equation. You can substitute and check. Now, what is phi of x t = 0 represent? It is nothing but the characteristic cone to the point x 0 t 0.

(Refer Slide Time: 19:24)

Why the Characteristic cone is also called Light cone?

- Characteristic cone is the union of all light rays that emanate from (x_0, t_0) which travel at the speed c , i.e.,

$$\left| \frac{dx}{dt} \right| = c.$$
- In other words,

$$\{(x, t) : c^2(t - t_0)^2 = \|x - x_0\|^2\} = \bigcup_{v \in \mathbb{R}^n, \|v\|=c} \{(x, t) : x = x_0 + v(t - t_0)\}.$$
- That's why the characteristic cone is also called Light cone.

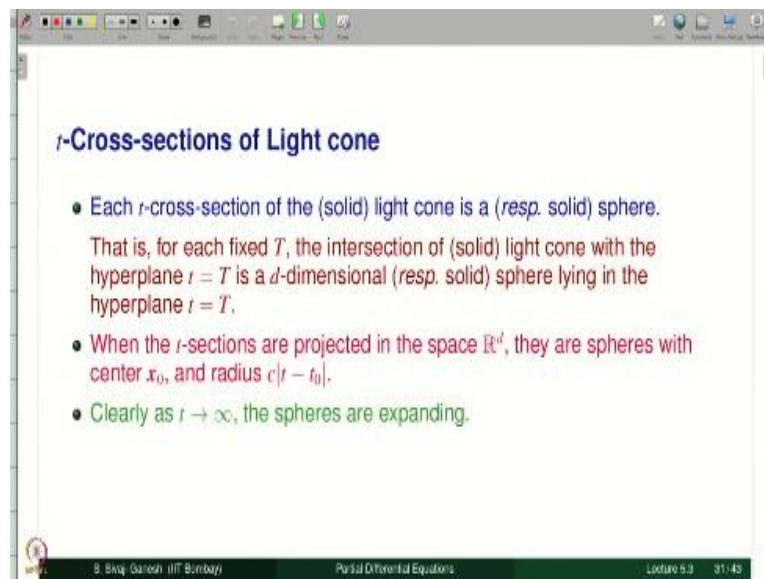

© Saq. Ganesh IIT Bombay Partial Differential Equations Lecture 9.3 30/45

So, why the characteristic cone is also called light cone? Characteristic cone is a union of all light rays that emanate from the point x 0 t 0 which is travel at the speed c that is mod dx by

$dt = c$, this is the speed, expression for the speed. In other words, this set which we have here is nothing but union of these sets. What is this? These are line passing through the point x_0 at t_0 because when $t = t_0$ in the direction v .

So, take all this direction or the vectors with this length c and then this is precisely that. So, both the sets are same. That is why the characteristic cone is also called light cone.

(Refer Slide Time: 20:21)

Speed is c . t cross sections of light cone, what they are? Each t cross section of the solid light cone will be a solid sphere. If you omit solid here, light cone will be sphere. Solid sphere means the interior is included that is for each fix T , the intersection of light cone with a hyperplane $t = T$ is a d dimensional sphere lying in the hyperplane $t = T$ that the sphere lying in d dimensions, not d dimensional sphere.

Sphere will be one dimension less. If you consider a solid sphere Yeah, so, let us not discuss that. It is the sphere lying in \mathbb{R}^d that is what the sentence means. When the t sections are projected in the space \mathbb{R}^d , they are the spheres with center x_0 and radius c times mod $t - t_0$. Clearly, as t goes to infinity, the spheres are expanding.

(Refer Slide Time: 21:22)

Idea of the proof of Causality principle for $d \geq 2$

- As in the case of $d = 1$, the main idea is to multiply wave equation with u_t and then integrate it on some part of the solid light cone and then perform integration by parts.
- The region of integration was a trapezium-shaped region for $d = 1$, which would now correspond to **Frustum of the cone**.
- Multiplying the homogeneous wave equation with u_t , and re-arranging the terms, yields

$$\sum_{i=1}^d \frac{\partial}{\partial x_i} (-c^2 u_t u_{x_i}) + \frac{\partial}{\partial t} \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} \|\nabla u\|^2 \right) = 0$$

S. Bhaq. Saroshi (IIT Bombay) Partial Differential Equations Lecture 9.3 32 / 43

So, what is the idea of the proof of causality principle in d greater than or equal to 2? As in the case of $d = 1$, the main idea is to multiply the wave equation with u_t and then integrate it on some part of the solid light cone and then perform integration by parts. The region of integration was a trapezium shaped region for $d = 1$ which would now correspond to frustum of the cone.

That is the reason why we use the notation F to denote the trapezium shaped region in $d = 1$, frustum of the cone. So, imagine, this kind of cone so, you cut this, so you have this. So, this is the frustum of the cone. So, we have a bottom portion; you have a top portion and you have a lateral portion. So, multiply the homogeneous wave equation with u_t and rearrange exactly in one dimension we have done. So, we get this.

(Refer Slide Time: 22:25)

Idea of the proof of Causality principle for $d \geq 2$ (contd.)

- Let $T < t_0$, and F denote the frustum of the solid light cone, contained between the hyperplanes $t = 0$ and $t = T$.
- Now proceeding as in $d = 1$, **domain of dependence inequality:**

$$\int_T \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} \|\nabla u\|^2 \right) d\sigma \leq \int_B \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} \|\nabla u\|^2 \right) d\sigma.$$

Here T and B denote the top and base of the frustum F .

With the above modifications, the proof given for $d = 1$ extends to $d = 2, 3$ cases. \square

We will see one more proof of uniqueness of solutions to the Cauchy problem using the energy method

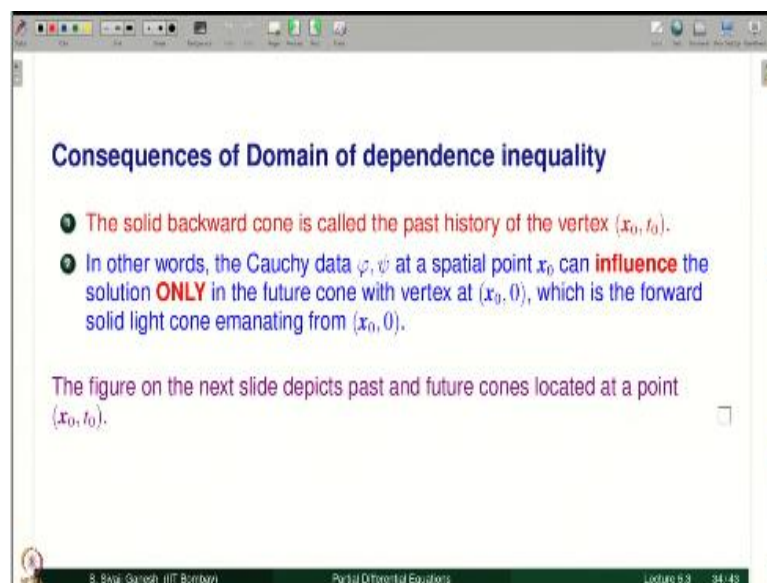

S. Bhaq. Saroshi (IIT Bombay) Partial Differential Equations Lecture 9.3 33 / 43

And then integrate on the first mod of cone defined by $t = 0$, this is the bottom portion; $t = T$ is the top portion. Now, preceding exactly as in $d = 1$, the domain of dependency inequality we obtain that is exactly the same integral over T is less than or integral or B . From here, the uniqueness of solutions to Cauchy problem follows again. You take u and B to be solutions.

Even for the non-homogeneous Cauchy problem, subtract $u - v$ as we call it as w that will satisfy the homogeneous wave equation with the homogeneous Cauchy data which means that integral on $v = 0$ on bottom that function and the derivative with respect to t will be 0. Therefore, we have this is 0 and this is true for every arbitrary T and therefore, in the first term, both of them coincide and hence, even at the point $x = 0, t = 0$, same proof.

So, with these modifications, the proof given for $d = 1$, it goes through for $d = 2, 3$ also. We will see one more proof of uniqueness using energy method later on.

(Refer Slide Time: 23:42)

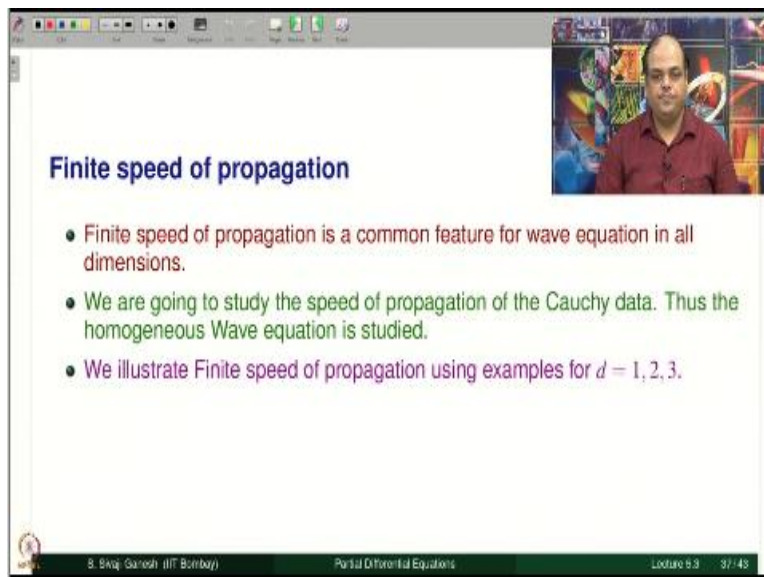

So, what are the consequences of domain of dependency inequality? The solid backward cone is called the past history of the vertex $x = 0, t = 0$. So, if this is $x = 0, t = 0$, the past cone we said, is less. So, this is the past and this will be the future of $t = 0$. In other words, the Cauchy data at a spatial point $x = 0$ can influence the solution only in the future cone with vertex at $x, 0$ which is forward solid light cone emanating from $x = 0, 0$.

The figure on the next slide depicts past and future cones located at a point $x = 0, t = 0$. So, we have already seen this picture.

(Refer Slide Time: 24:38)

(Refer Slide Time: 24:41)

So, finite speed of propagation. Finite speed of propagation is a common feature for wave equation in all dimensions. We are going to study the speed of propagation of the Cauchy data. Thus, the homogeneous wave equation is studied. We illustrate finite propagation using examples for $d = 1, 2, 3$.

(Refer Slide Time: 25:01)

Example 1. $d = 1$

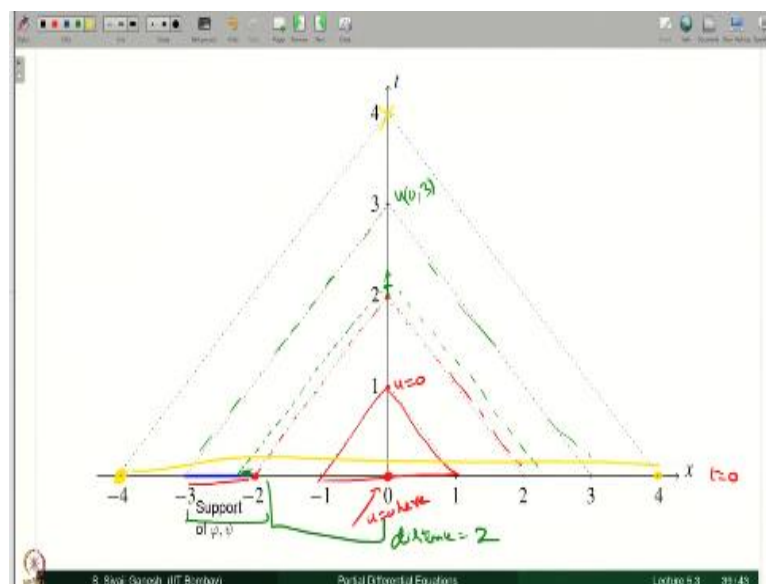

- Let the initial data φ and ψ be zero outside of the interval $(-3, -2)$. Thus $u(0, 0) = 0$ as $u(0, 0) = \varphi(0) = 0$.
- Let us now study the behaviour of $u(0, t)$ for $t > 0$.
 - For $t > 0$ such that $-ct > -2$, i.e., $t < \frac{2}{c}$, $u(0, t) = 0$. That is the information (Cauchy data) at $t = 0$ has not reached the point $x_0 = 0$ till $t_1 = \frac{2}{c}$, from which time the information will be received at $x_0 = 0$.
 - Thus it took a time of $t_1 = \frac{2}{c}$ to travel a distance of 2, and thus the speed is c .
 - $u(0, t)$ remains zero till $t = 2$.
 - An illustration of this example is given on the next slide.

9. Saig. Ganesh (IIT Bombay) Partial Differential Equations Lecture 9.3 39/43

So, let us consider $d = 1$; let the initial data φ and ψ be 0 outside this interval $-3, -2$. Therefore, u of $0,0$ is 0; $x = 0$ $t = 0$ that is actually φ of 0. Zero is not in this interval therefore φ is 0. Let us now study the behaviour of u of 0 t that means I am standing at $x = 0$, I want to study what happens for t positive. For t positive such that $-ct$ is bigger than -2 that is t less than 2 by c , u of 0 t will be 0.

We will see these in a picture. It will be very easy. So, that is the information at $t = 0$ has not reached a point $x = 0$ till this time $t = 2$ by c , from which time the information will be received at this point. Thus, it took a time of 2 by c to travel a distance of 2. Why the distance of 2? This interval is at a distance of 2 from the point $x = 0$ and thus, the speed is c . u of 0 t remains 0 till $t = 2$. An illustration of this example is given on the next slide.

(Refer Slide Time: 26:27)

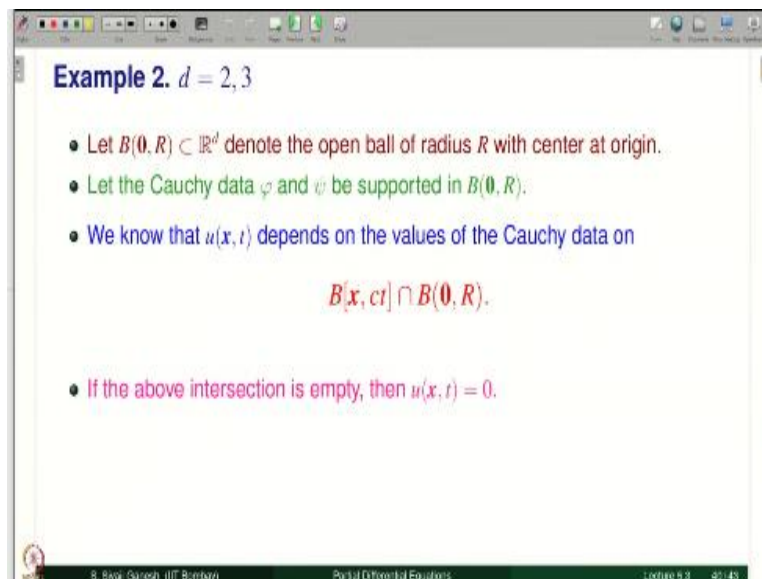

So, here, we are standing at this point $x_0 = 0$. Right now, at time $t = 0$ because this is $t = 0$; the information is only here in this interval $-3, 2$ outside that ϕ and ψ of 0. Therefore, u is 0 here. Let us consider this instant time instant one, then also if you see from our formula, this does not intersect the interval -3 to 2 , therefore, u is still 0 here. When you go to 2 that is when you pick up some information from here from the interval, it has reached this point 0 at time $t = 2$ because it is hitting this point.

Possibly, ϕ is nonzero here who knows but because the support of ϕ and ψ of 0, it will be 0 only. Here, ϕ of 0, ϕ of -2 , ψ of -2 will be 0. So, till time 2, you will not reach. The moment you cause time 2, 2 plus something this time, then definitely you are intersecting this piece, this side you will get nothing; this side, anyway ϕ and ψ of 0. So, you may pick up some information from here that means information from this interval $-3, -2$, where the support of ϕ lies is reaching the point $x_0 = 0$ which is at a distance of 2; distance is 2.

It takes time 2 time 2 units. So, this example is with $c = 1$. So, speed is 1, distance is 2, so, you take 2 units of time to reach information. So after 2, the information starts coming. For example, if you are at 3 as you see here, the domain dependence for u of $0, 3$ contains $-3, -2$ intersection on empty In fact, in this example, it contains. Now, if you are at this point 4, time 4 at this point, you see that this is interval; definitely in this, you have the support of ϕ and ψ . So, information has reached there.

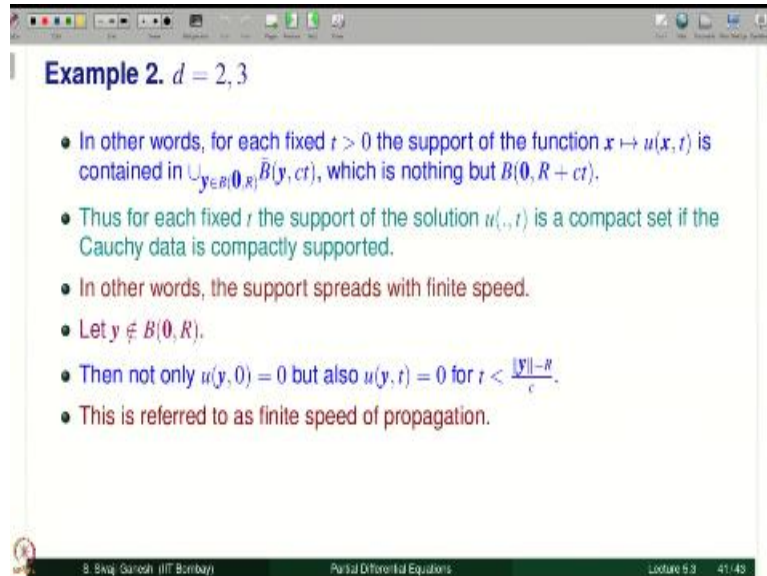

(Refer Slide Time: 28:57)

So in $d = 2, 3$, let us look at. Consider a ball B of $0, R$, centre 0 , at the origin and radius R , let it do not open ball of radius R with central origin, suppose that the Cauchy data is supported

inside this ball. We know that u of x, t depends on the value so, the Cauchy data on this B , this is a closed ball x, t intersection $B(0, R)$, only this is non-empty, we have nonzero solution. Otherwise, it will be 0. So if the above intersection is empty, u will be 0.

(Refer Slide Time: 29:34)

In other words, for each fix t positive, the support of the function, x going to u of x, t is contained in union over y in this ball of radius R centre origin of the closed ball with centre as y and radius ct which is nothing but this ball, ball centre 0 radius R plus ct . Thus, for each fixed t , the support of the solution is a compact set if the Cauchy data is compactly supported. We have observed this in $d = 1$ and illustrated with the picture also.

In other words, the support spreads with finite speed, let y be 0 in this ball of radius R with centre 0 , what will happen? Then not only u of $y, 0$ is 0 , this is the initial time, ϕ and ψ are concentrated inside $v(0, R)$; outside that ϕ and ψ are 0 . Why is the point outside that? Therefore, u of $y, 0$ is what? It is ϕ of y and y is not in this ball, therefore, this is 0 . But also u of y, t will continue to be 0 for all times up to $\|y\| - R$ by c . This is referred to as finite speed of propagation.

The image shows a presentation slide with a white background and a dark green footer. The slide is titled "Summary" in blue. It contains three main points, each with a colored circular icon: 1. "Derived Domain of dependence inequality" (red icon), 2. "Using Domain of dependence inequality," (green icon), and 3. "Proved uniqueness of solutions to the Cauchy problem." (blue icon). Below the second point, there are two sub-points: "Revisited domains of dependence and influence with Past-Future, Cause-Effect points of view." (red text) and "Cause-Effect points of view." (red text). The footer contains the text "S. Bhaq. Ganesh (IIT Bombay)", "Partial Differential Equations", and "Lecture 5.3 42/48".

Summary

- 1 Derived Domain of dependence inequality
- 2 Using Domain of dependence inequality,
 - Proved uniqueness of solutions to the Cauchy problem.
 - Revisited domains of dependence and influence with Past-Future, Cause-Effect points of view.

S. Bhaq. Ganesh (IIT Bombay) Partial Differential Equations Lecture 5.3 42/48

So, what we have done in this lecture is we have derived the domain of dependency inequality for $d = 1$. For the $d = 3$, we just gave the idea. So, using domain of dependency inequality, we proved uniqueness of solutions to the Cauchy problem. The second proof of uniqueness and we revisited domains of dependence and influence with past-future, cause effect points of view. Thank you.
