Lecture – 55
Cauchy Problem for Heat Equation - 1

(Refer Slide Time: 00:35)

Welcome, we begin the study of heat equation starting from this lecture. In this lecture, we are going to take a few preliminary steps into the solution of Cauchy problem for the heat equation. The outline of this lecture is as follows. First, we introduce what is Cauchy problem for heat equation and take the first steps in solving the Cauchy problem for homogeneous heat equation. In the next lecture, we are going to complete the study of the Cauchy problem for nonhomogeneous heat equation.

(Refer Slide Time: 00:57)

Given functions f, φ , Cauchy problem is to solve

$$u_t - u_{xx} = f(x, t), \quad x \in \mathbb{R}, t > 0,$$

$$u(x, 0) = \varphi(x), \quad \text{for } x \in \mathbb{R}.$$

So, what is Cauchy problem for heat equation? Given functions f, φ on appropriate domains Cauchy problem is to solve $u_t - u_{xx} = f$ of x, t ; x belonging to \mathbb{R} and t positive and u of $x, 0 = \varphi$ of x for x in \mathbb{R} .

(Refer Slide Time: 01:17)

Notation: $C^{2,1}(\mathbb{R} \times (0, \infty))$

The function space $C^{2,1}(\mathbb{R} \times (0, \infty))$ consists of A

$$u : \mathbb{R} \times (0, \infty) \rightarrow \mathbb{R}$$

such that

- u is continuous on $\mathbb{R} \times (0, \infty)$
- u_t, u_x are continuous on $\mathbb{R} \times (0, \infty)$ i.e., $u \in C^1(\mathbb{R} \times (0, \infty))$.
- u_{xx} is continuous on $\mathbb{R} \times (0, \infty)$

In $C^{2,1}$, 2 and 1 stand for the number of derivatives w.r.t. x and t variables respectively.

Notation: $C^{2,1}$ of \mathbb{R} cross $(0, \infty)$. In case you have seen this notation $C^{2,1}$ somewhere else, you forget about that. It is not about that notation; it is a notation restricted to the heat equation study. So, the functions space $C^{2,1}$ of \mathbb{R} cross $(0, \infty)$ consists of all functions defined on the domain \mathbb{R} cross $(0, \infty)$ taking values in real numbers such that u is continuous on \mathbb{R} cross $(0, \infty)$; u_t, u_x are continuous on \mathbb{R} cross $(0, \infty)$ that is u is C^1 of \mathbb{R} cross $(0, \infty)$; u_{xx} is continuous on \mathbb{R} cross $(0, \infty)$.

In this notation $C^{2,1}$ and 1 stands for the number of derivatives with respect to x and t variables respectively. As you see with respect to x , we have two derivatives that is why the 2 here and this 1 is for one derivative of u with respect to t .

(Refer Slide Time: 02:29)

Definition. Solution to Cauchy problem

Let $u := u(x, t)$ be a function such that

$$u \in C^{2,1}(\mathbb{R} \times (0, \infty)) \cap C(\mathbb{R} \times [0, \infty)).$$

u is said to be a solution to the Cauchy problem if

- u satisfies the heat equation $u_t - u_{xx} = f$ for $x \in \mathbb{R}$ and $t > 0$; and
- $u(x, 0) = \varphi(x)$ holds for $x \in \mathbb{R}$.

Let us define what is the meaning of solution to the Cauchy problem. Let u be a function such that u is $C^{2,1}$ of \mathbb{R} cross $(0, \infty)$ and that is intersection C of \mathbb{R} cross closed $[0, \infty)$. Observe here it is open $(0, \infty)$, this is closed $[0, \infty)$. The u is said to be a solution to the Cauchy problem if u satisfies the heat equation $u_t - u_{xx} = f$ at every point $(x, t) = f(x, t)$ for x in \mathbb{R} and t positive that holds and $u(x, 0) = \varphi(x)$ that also holds for every x in \mathbb{R} .

(Refer Slide Time: 03:17)

The Cauchy problem

$$u_t - u_{xx} = f(x, t), \quad x \in \mathbb{R}, \quad t > 0,$$

$$u(x, 0) = \varphi(x), \quad \text{for } x \in \mathbb{R}$$

may be solved in two steps.

- 1 **Step 1.** Solve the Cauchy problem with $f \equiv 0$.
- 2 **Step 2.** Use Duhamel principle to get a solution to the Nonhomogeneous equation with zero Cauchy data.
- 3 **Superposition of the two solutions in Steps 1 and 2** would then give solution to the Cauchy problem for nonhomogeneous equation.

So, the Cauchy problem $u_t - u_{xx}$, you may call this as the operator \mathcal{h} of u equals to f of x, t and $u(x, 0) = \varphi(x)$ on appropriate domains $x \in \mathbb{R}, t > 0$ here and $x \in \mathbb{R}$

here may be solved in two steps. Step 1, solve the Cauchy problem with f identically equal to 0. Step 2, use Duhamel principle to get a solution to the nonhomogeneous equation with zero Cauchy data. And superposition of the two solutions which are obtained in step 1 and 2 would then give solution to the Cauchy problem for a nonhomogeneous equation that is solution to this problem.

(Refer Slide Time: 04:09)

Cauchy problem for Homogeneous Heat Equation

$$u_t - u_{xx} = 0, \quad x \in \mathbb{R}, \quad t > 0,$$

$$u(x, 0) = \varphi(x), \quad \text{for } x \in \mathbb{R}.$$

As a first step, obtain a general solution to

$$u_t - u_{xx} = 0.$$

From it, find a solution to Cauchy problem

So, Cauchy problem for homogeneous heat equation $u_t - u_{xx} = 0$ and $u(x, 0) = \varphi(x)$. So, the first step; obtain a general solution to this equation, a solution which satisfies $u(x, 0) = \varphi(x)$ that is the idea, let us try it out.

(Refer Slide Time: 04:27)

Exercises!

Whenever u is a solution to $u_t - u_{xx} = 0$,

- any derivative of u is also a solution.
- Let $a > 0$. Define $w(x, t) := u(ax, a^2t)$. Then w is also a solution.
- Fix $y \in \mathbb{R}$. Define $w(x, t) := u(x - y, t)$. Then w is also a solution.

Before that some exercises. Whenever u is a solution to $u_t - u_{xx} = 0$ any derivative of u is also solution assuming that such derivatives exist okay. And let a be positive defined w of x, t

$w = u(ax, a^2t)$. Then w is also a solution. Fix y in \mathbb{R} and look at a translate of u , $u(x - y, t)$ call it w of x, t that w is also a solution.

(Refer Slide Time: 05:08)

Solving Heat equation using a similarity transformation

Key observation: For every $a > 0$, Heat equation is invariant under the change of coordinates

$$z := ax, \tau := a^2t.$$

- $$\frac{z^2}{\tau} = \frac{x^2}{t}.$$
- We look for solutions to Heat equation respecting the above symmetries.

$$v := v(z), u(x, t) = v\left(\frac{x}{\sqrt{t}}\right)$$

Let us solve heat equation using a similarity transformation. We will see what that means. A key observation is as follows. For every a positive, heat equation is invariant under the change of coordinates. That means if you shift from x, t to z, τ , the heat equation now will become $w_\tau - w_{zz} = 0$. Observe this z^2 by τ is x^2 by t . So, we look for solutions to heat equation respecting the symmetries.

So, let v be a function of one variable v of z , okay this z is different from this z , I should have called it v of some other variable s . So, u of $x, t = v$ of x by root t . So take a function of one variable and look for u of x, t as v of x by root t . So, x by root t is coming from this equation x^2 by t equivalently x^2 root t .

(Refer Slide Time: 06:11)

Solving Heat equation using a similarity trans (contd.)

- Substituting the ansatz

$$u(x, t) = v\left(\frac{x}{\sqrt{t}}\right)$$

into heat equation yields

$$\frac{d^2v}{dz^2} + \frac{z}{2} \frac{dv}{dz} = 0. \quad (\text{ODE1})$$

- Such transformations are called **similarity transformations**, and they help in reducing the number of independent variables. PDE became ODE here!

So, substituting this ansatz u of x , $t = v$ of x by root t into heat equation gives us this equation very easy to check, I am not going to prove this. Now, such transformations are called similarity transformation, which transformation this instead of looking for x , t look for x square root t and they help in reducing the number of independent variables. PDE became ODE in our example. The heat equation became this ODE.

(Refer Slide Time: 06:43)

Solving Heat equation using a similarity trans (contd.)

- The equation

$$\frac{d^2v}{dz^2} + \frac{z}{2} \frac{dv}{dz} = 0$$

can be solved explicitly.

- Its general solution is given by

$$v(z) = C_1 \int_0^z \exp\left(-\frac{s^2}{4}\right) ds + C_2,$$

where C_1, C_2 are arbitrary constants.

So, the equation which we have obtained on the earlier slide it can be solved explicitly. So, its general solution is given by this $v(z) = C_1 \int_0^z \exp(-s^2/4) ds + C_2$ where C_1 and C_2 are arbitrary constants.

(Refer Slide Time: 07:04)

Solving Heat equation using a similarity trans (contd.)

$$v(z) = C_1 \int_0^z \exp\left(-\frac{s^2}{4}\right) ds + C_2.$$

Thus u is given by

$$u(x, t) = C_1 \int_0^{\frac{x}{\sqrt{t}}} \exp\left(-\frac{s^2}{4}\right) ds + C_2.$$

So, therefore, u of x, t is v of x by root t . So put $z = x$ by root t . So, that is only here, z is only here, so it is only here. So, this is an expression for u of x, t . Now, we want to make sure u of $x, 0$ is $\phi(x)$, then we are done, we have solved the Cauchy problem for the homogeneous heat equation.

(Refer Slide Time: 07:28)

Solving Heat equation using a similarity trans (contd.)

$$u(x, t) = C_1 \int_0^{\frac{x}{\sqrt{t}}} \exp\left(-\frac{s^2}{4}\right) ds + C_2$$

Note that

$$u(x, 0) := \lim_{t \rightarrow 0^+} u(x, t) = \begin{cases} -C_1\sqrt{\pi} + C_2 & \text{if } x < 0, \\ C_1\sqrt{\pi} + C_2 & \text{if } x > 0. \end{cases}$$

$u := u(x, t)$ is smooth for $t > 0$, however, $u(x, 0)$ has a jump discontinuity. No way to obtain a solution to Cauchy problem!

What can we do for solving Cauchy problem NOW?

Let us see what is u of $x, 0$? u of $x, 0$ is limit of u of x, t as t goes to 0^+ which is actually $-C_1\sqrt{\pi} + C_2$ if x is negative and if x is positive it is $C_1\sqrt{\pi} + C_2$, please check this. Now, u which is given here, u of x, t is smooth function for every t positive, only at $t = 0$ there is some issue. If t is positive it is an indefinite integral of course with this variable here of some nice function, smooth function C^∞ function. So, therefore, u is smooth, there is no problem for u .

However, $u(x, 0)$ has a jump discontinuity. But in any case, there is no way to obtain a solution to our Cauchy problem, we want $u(x, 0) = \phi(x)$. How will I get $\phi(x)$ from this? This is just piecewise constant function with some jump discontinuity if C_1 is nonzero. If C_1 is 0, of course it is just a constant function. So, we need to exploit this of varying C_1 if possible and try to get solution, but there is no way $u(x, 0)$ is not going to be $\phi(x)$. So, what can we do for solving Cauchy problem now?

(Refer Slide Time: 08:52)

For compactly supported ψ , observe

$$\begin{aligned} \int_{\mathbb{R}} u(x, 0) \psi'(x) dx &= \int_{-\infty}^0 u(x, 0) \psi'(x) dx + \int_0^{\infty} u(x, 0) \psi'(x) dx \\ &= \int_{-\infty}^0 (-C_1 \sqrt{\pi} + C_2) \psi'(x) dx + \int_0^{\infty} (C_1 \sqrt{\pi} + C_2) \psi'(x) dx \\ &= (-C_1 \sqrt{\pi} + C_2) \psi(0) - (C_1 \sqrt{\pi} + C_2) \psi(0) \\ &= -2C_1 \sqrt{\pi} \psi(0) \end{aligned}$$

If the function $u(x, 0)$ were smooth, we would have had

$$\int_{\mathbb{R}} u(x, 0) \psi'(x) dx = - \int_{\mathbb{R}} u_x(x, 0) \psi(x) dx$$

Let us observe this for compactly supported function ψ , look at $u(x, 0)$ into $\psi'(x)$. Of course, this integral can be split into minus infinity to 0 + 0 to infinity. I have not done anything, the integration domain is split into two domains. I am going to substitute the value of $u(x, 0)$. For x negative we have $u(x, 0)$ this. For x positive $u(x, 0)$ is this. Now we can do integration, right this is a constant.

So minus infinity to 0 of $\psi'(x)$ is $\psi(0)$. And here this is constant, so 0 to infinity of $\psi'(x)$ is minus $\psi(0)$, ψ is having compact support, so the infinity does not matter, only 0 matters. If you simplify you get this $-2 C_1 \sqrt{\pi} \psi(0)$. If the function $u(x, 0)$ was smooth and not like this, what we would have had is integral $u(x, 0) \psi'(x) = - \int_{\mathbb{R}} u_x(x, 0) \psi(x) dx$.

(Refer Slide Time: 10:12)

For compactly supported ψ , we obtained on the

$$\int_{\mathbb{R}} u(x, 0) \psi'(x) dx = -2C_1 \sqrt{\pi} \psi(0)$$

On the other hand, for smooth $u(x, 0)$ we have

$$\int_{\mathbb{R}} u(x, 0) \psi'(x) dx = - \int_{\mathbb{R}} u_x(x, 0) \psi(x) dx$$

Thus, roughly speaking, we have

$$u_x(x, 0) \sim 2C_1 \sqrt{\pi} \delta_0$$

For $y \in \mathbb{R}$, by a translation,

$$u_x(x - y, 0) \sim 2C_1 \sqrt{\pi} \delta_y$$

So, we obtained on the last slide this expression. For smooth functions, u of $x, 0$ we would get this. So, in some sense this and this are related loosely, roughly speaking. Roughly speaking u_x of $x, 0$ is like $2C_1 \sqrt{\pi} \delta_0$, this is the Dirac delta. Dirac delta, when you integrate, loosely speaking when you integrate against some function will give you the value of the function at the point 0 that is why you have ψ of 0. By translation, we can make this happen at any y . So, u_x of $x - y, 0$ will be δ_y instead of δ_0 .

(Refer Slide Time: 11:02)

From the observations on last slide, it appears

$$u_x(x, t)$$

would be useful to solve Cauchy problem.

$$u_x(x, t) = \frac{C_1}{\sqrt{t}} \exp\left(-\frac{x^2}{4t}\right). \quad (\text{FSol1})$$

Choose C_1 so that $\int_{\mathbb{R}} u_x(x, t) dx = 1$, and this gives $C_1 = \frac{1}{2\sqrt{\pi}}$.

So, from the observations on the last slide, it appears that u_x of x, t would be useful to solve Cauchy problem, u_x of x, t of course is a smooth function, there is no problem for t positive. What happens at $t = 0$? It looks like the Dirac delta function relative of that. So, choose C_1 so that this integral is 1 that will give us C_1 to be 1 by $2\sqrt{\pi}$. So, therefore, u_x of x, t is 1

by $2\sqrt{\pi t}$ into exponential $-x^2$ by $4t$. This is going to play a crucial role in the solution of the Cauchy problem for homogeneous heat equation.

(Refer Slide Time: 11:44)

• The function

$$u_x(x, t) = \frac{C_1}{\sqrt{t}} \exp\left(-\frac{x^2}{4t}\right).$$

(FS011)

is smooth for $t > 0$, what happens to it as $t \rightarrow 0$?

- It approximates Dirac delta distribution. Reasons: integral is one, and as $t \rightarrow 0+$ one can observe that graph of $x \mapsto u_x(x, t)$ steepens, and starts to concentrate at $x = 0$.
- See the figure on the next slide.

So, as observed this function is smooth for t positive. And what happens to it as t goes to 0 ? We will see some picture on the next slide. It approximates this Dirac delta distribution, in case you do not know what this is, simply ignore what I have said. The reason is that it has integral 1, for every t integral 1 with respect to x and as t goes to $0+$ one can observe that the graph steepens and start to concentrate at $x = 0$. Look at the picture on the next slide.

(Refer Slide Time: 12:22)

So, here $u_x(x, t)$ graphs are drawn for various times; $t = 2$ is in blue, see here, these are one. The $t = 1$ is in this red colour and yellow is $t = 0.25$. You see it is getting steep and it steepens around 0, at the same time the values are tending to 0 and other places, not becoming 0, but

then getting closer and closer to 0 as t goes to 0. So, $t = 0.1$ is in this here in magenta colour, see this steepens because the area it has to maintain to be 1, right, area under this curve.

And this is shrinking where u has big value, it is becoming smaller and smaller and therefore it is becoming bigger and bigger near $x = 0$. So the u of x , t is concentrating near $x = 0$ as t is going to 0.

(Refer Slide Time: 13:27)

- One can make $u_x(x, 0)$ to concentrate around any $y \in \mathbb{R}$ is consider $u_x(x - y, t)$ instead of $u_x(x, t)$.

$$u_x(x - y, 0) \sim \delta_y$$

- "The collection $u_x(x - y, 0)$ indexed by y forms a basis" in the sense that

$$\int_{\mathbb{R}} u_x(x - y, 0) \varphi(x) dx = \varphi(y)$$

- Thus we expect that superposition of $u_x(x - y, t) \varphi(y)$ yields a solution to the Cauchy problem. This will be formalized as a theorem in the next lecture.

So one can make u of x , 0 to concentrate around any y by a translation, we already observed that. So you consider u of $x - y$, t instead of u of x , t ; u of $x - y$, 0 will be like delta y . The collection u of $x - y$, 0 indexed by y forms a basis roughly speaking in the sense that this when you integrate you will get φ of y . Thus, we expect that the superposition of u of $x - y$, t into φ of y yields a solution to the Cauchy problem.

If I can get my φ of y using u of $x - y$, 0 I hope that I can get my u of x , t with φ as the initial data using u of $x - y$, t that is a hope we have. This will be formulated as a theorem in the next lecture.

(Refer Slide Time: 14:33)

Analogy with the case of Laplace operator

- We looked at symmetries of the Laplace operator and motivated by them, we tried special (radial) solutions.
- In Lecture 6.2, we obtained fundamental solution for Laplace equation.
- In the case of Heat equation also, we looked for solutions which respected the symmetry properties of the heat equation.
- For Laplace equation, the fundamental solution picked up Dirac delta function in space (there was no time of course).
- For heat equation, a similar idea resulted in picking up Dirac delta at initial time, and that's why we will be able to solve the initial value problem.

I would like to give an analogy with the case of the Laplace operator. We looked at symmetries of the Laplace operator and motivated by them. We tried special solutions that is radial solutions. And that gave us fundamental solution for the Laplace equation that is done in lecture 6.2. In the case of heat equation also, we looked for solutions which respected symmetry properties that heat equation enjoys.

For Laplace equation the fundamental solution picked up Dirac delta function in the space. Of course, there is no time in Laplace case. For heat equation, a similar idea resulted in picking up Dirac delta at initial time and that is why we will be able to solve the initial value problem. We will continue this in the next lecture.

(Refer Slide Time: 15:27)

Heat Kernel

We define fundamental solution by

$$K(x, t) = \frac{1}{2\sqrt{\pi t}} \exp\left(-\frac{x^2}{4t}\right).$$

- Of course, we need to verify that fundamental solution defined above has the properties that are expected of a fundamental solution.
- We will take it up in the next lecture.

Let us define what is called heat Kernel that is $\frac{1}{\sqrt{2\pi t}} \exp\left(-\frac{x^2}{4t}\right)$, K of x, t . This is also known as heat Kernel, our fundamental solution, we can call fundamental solution. Of course, we need to verify that the fundamental solution defined above has the properties that are expected of a fundamental solution. We will take it up in the next lecture. Thank you.
