Connected components

(Refer Slide Time: 00:16)

The screenshot shows a video lecture interface. On the left, a table of contents lists modules from 30 to 46. The current slide is titled 'Module-34 Connected components'. The main content area contains 'Theorem 3.22' which states: 'Let $f : X \rightarrow Y$ be a continuous function. Then for every (path) connected subset Z of X , $f(Z)$ is (path) connected.' Below this is a 'Proof' section that begins with 'We may as well assume that $Z = X$ and f is surjective. Now if $Y = A \cup B$ then it follows that $X = f^{-1}(A) \cup f^{-1}(B)$. This shows that if X is connected so is Y . If γ is a path in X joining a to b then it follows that $f \circ \gamma$ is a path in Y joining $f(a)$ to $f(b)$. From this it follows that if X is path connected, then so is Y .' The bottom of the slide shows the NPTEL logo and the course title 'NPTEL-NOC An Introductory Course on Point-Set Topology, I'.

Welcome to module 34 of Point Set Topology Part-I. Last time, we introduced the notion of connectedness, motivating it from the notion of path connectedness and then, relating it to intermediate value theorem, least upper bound property etcetera. So, we will continue now the study of connectedness.

So, here is a simple theorem which says that if you have a continuous function from one space to another space, it will take a connected or a path connected subspace connected or a path connected space accordingly. So, it is actually two different statements here.

By taking a subset Z which is say connected or path connected and restricting the function to that and to the domain Z on the codomain $f(Z)$, we can as well assume that f itself is surjective and make the hypothesis that X itself is connected or path connected. So, let us first look at when X is connected, I want to show that Y is connected ok.

So, take a separation of Y , Y equal to $A|B$, it pulls back to a separation of X via f so, all that you have to do is $f^{-1}(A)|f^{-1}(B)$ that will be separation of X , pure set theoretic claim. Continuity of f is used only to see that these two sets, $f^{-1}(A)$ and $f^{-1}(B)$ are closed. Rest of the things, disjointness, union is the whole of X etc are just pure set theoretic ok? So, that proves that image of a connected space is connected.

Now, let us assume X is path connected and we want to show that Y is path connected, but remember now, I have assumed f is surjective so, given any two points say here in Y , y_1 and y_2 whatever, they are $f(a)$ and $f(b)$ for some points a and b in X ok? But a and b inside X can be joined by a path γ . γ is a path in X joining a and b . Then, $f \circ \gamma$ will be a path joining $f(a)$ and $f(b)$. that shows that Y is path connected.

(Refer Slide Time: 03:34)

So, we had defined long back that a property of topological spaces is said to be topological property or a topological invariant if the following holds: whenever P is true for a space, it must be true for all spaces Y which are homeomorphic to X . So, that was the definition 1.59, I am just recalling it ok.

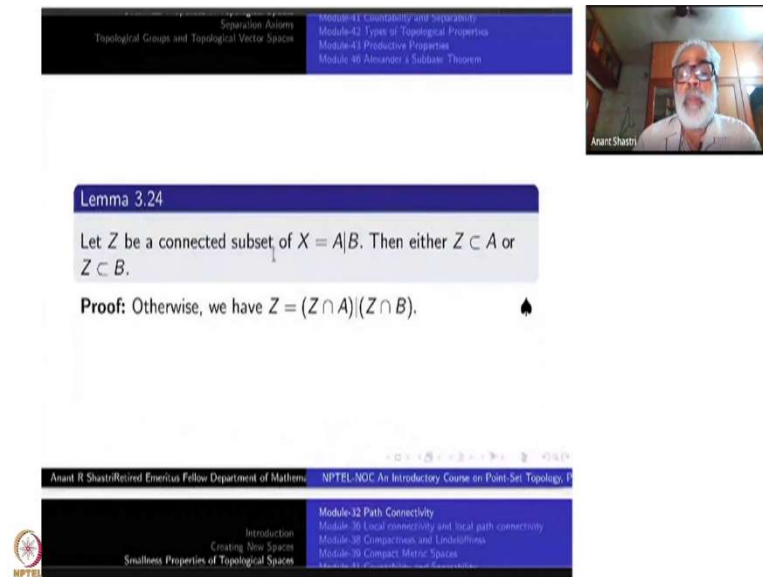

(Refer Slide Time: 04:16)

The image shows a screenshot of a video lecture. At the top, a blue header bar contains the text "Module: 46 Alexander's Subbase Theorem". Below this, a white box with a blue border contains the text "Remark 3.23". The text in the box reads: "It follows that connectivity and path connectivity are topological invariants. Because of the above fundamental property, it becomes natural to decompose a given topological space into connected subsets in an economical way. This leads to the notion of connected components." To the right of the slide is a small video feed of a man with glasses and a white beard, identified as "Anand Shastri". At the bottom of the slide, there is a navigation bar with the text "Anand R Shastri Retired Emeritus Fellow Department of Mathematics, NPTEL: NOC An Introductory Course on Point-Set Topology, I". Below the navigation bar is a table of contents with the following items: "Introduction", "Smallest Properties of Topological Spaces", "Separation Axioms", "Topological Groups and Topological Vector Spaces", "Module:32 Path Connectivity", "Module:36 Local connectivity and local path connectivity", "Module:38 Compactness and Lindelöfness", "Module:39 Compact Metric Spaces", "Module:41 Countability and Separability", "Module:42 Types of Topological Properties", and "Module:43 Productive Properties".

So, because image of a connected set is connected automatically under a homeomorphism, image of a connected set will be connected because homeomorphisms are onto. So, homeomorphism preserves connectivity, similarly, it preserves path connectivity also. These two are topological invariants ok?

Because of this property, what happens is whenever you are studying some connected spaces and so on, you can actually assume the whole space is connected concentrate on a connected part of it ok and then discuss the whole thing because once we have that continuous functions from there, we will always be inside the same connected set, after all we are all the time studying continuous functions. So, lot of such discussions can be isolated just around a connected set. So, this leads us to the notion of what is called connected components.

(Refer Slide Time: 05:37)

The screenshot shows a video lecture interface. At the top, there are navigation menus for 'Separation Axioms' and 'Topological Groups and Topological Vector Spaces'. A video feed of the lecturer, Anant Shastri, is visible in the top right corner. The main content area displays the following text:

Lemma 3.24
Let Z be a connected subset of $X = A \cup B$. Then either $Z \subset A$ or $Z \subset B$.
Proof: Otherwise, we have $Z = (Z \cap A) \cup (Z \cap B)$.

At the bottom, there are navigation controls and a footer with the NPTEL logo and the text 'Anant B Shastri Retired Emeritus Fellow Department of Mathematics, NPTEL-NOC An Introductory Course on Point-Set Topology, I'.

Suppose Z is a connected subset of X and X has a separation, then either Z is inside A or it is inside B . So, this is the property of a connected set otherwise what happens? You have to just take the restriction to Z of the separation. Z contained inside X , $Z \cap A$, $Z \cap B$ that is separation of Z . Only thing is you do not know whether each of these subsets are nonempty, $Z \cap A$ will be nonempty if Z is not contained inside B and vice versa if it is not contained inside A , then this will be nonempty.

So, if both of them are nonempty, that will be a contradiction to the fact that is Z is connected. So, one of them must be empty which means Z is contained inside the other one.

(Refer Slide Time: 06:58)

The screenshot shows a video lecture interface. At the top, a blue header bar contains the text "Module 43 Proximate Properties" and "Module 40 Alexander's Subbase Theorem". On the right side, there is a small video window showing a man with glasses and a white beard, identified as "Anant Shastri". The main content area has a blue header "Theorem 3.25" followed by the text: "Let $X = X_1 \cup X_2$. Suppose X_1, X_2 are connected and $X_1 \cap X_2$ is non empty. Then X is connected." Below this is the "Proof": "Let $X = A \cup B$. Let $x \in X_1 \cap X_2$. We may assume that $x \in A$. But then from the above lemma, it follows that $X_1 \subset A$ for $i = 1, 2$. Hence, $X = A$ and $B = \emptyset$, a contradiction." At the bottom, there is a navigation bar with the NPTEL logo and a list of modules: "Introduction", "Creating New Spaces", "Smallness Properties of Topological Spaces", "Separation Axioms", "Topological Groups and Topological Vector Spaces", "Module 32 Path Connectivity", "Module 36 Local connectivity and local path connectivity", "Module 38 Compactness and Lindelöfness", "Module 39 Compact Metric Spaces", "Module 41 Countability and Separability", and "Module 42 Types of Topological Properties".

Let us understand one more thing about this connectivity. Suppose you have X as a union of two subspaces which are both connected and the intersection is nonempty, then X itself is connected. Later on we will generalize this one ok.

So, this is just a trick using the previous lemma. Suppose this union has a separation ok? I have assumed that $X_1 \cap X_2$ is nonempty so, take x to be a point in the intersection, then x being a single point, it must be either inside A or B and not both. You can assume that it is inside A , by changing the notation if you need.

But then, from the above lemma, it follows that since X_1 contains x right and X_1 is connected, ok? so, X_1 must be contained completely inside A . It is contained in A or B is the previous lemma, but since already x is inside A , it is a common point with X_1 so, it follows that X_1 is inside A . The same argument for X_2 also. So, both X_i 's are inside A . That means, B is empty. So, that is a contradiction which just means that there is no separation of X and hence X is connected.

So, you can see that already this can be very easily to generalized for any family X_1, X_2, \dots, X_n etc not necessarily even finite ok. Here, I have not used any indexing set in the

argument. This can be just arbitrary indexing set, it will be applicable for all. That is just an observation you can make once you have understood for X_1 and X_2 .

(Refer Slide Time: 09:09)

The screenshot shows a video lecture interface. On the right is a small video window of the lecturer, Anant Shrivastava. The main slide contains the following text:

Definition 3.26
 Let P be a statement about subsets of a given set X . We say $A \subset X$ is maximal with respect to P if A satisfies P and whenever $A \subset B \subset X$ and B satisfies P , then we must have $A = B$.

Below the definition is a navigation menu with the following items:

- Introduction
- Creating New Spaces
- Smallest Properties of Topological Spaces
- Separation Axioms
- Topological Groups and Topological Vector Spaces
- Module-32 Path Connectivity
- Module-33 Local connectivity and local path connectivity
- Module-34 Compactness and Lindelöfness
- Module-35 Compact Metric Spaces
- Module-36 Countability and Separability
- Module-37 Types of Topological Properties
- Module-38 Productive Properties
- Module-39 Alexander's Subbase Theorem

So, now we make a definition motivated by especially this lemma ok? And then, this theorem here ok. Let P be a statement about subsets of a given set X , this is general definition first of all just to tell you what is the meaning of this maximum.

We say a subset of X is maximal with respect to P , first of all it must satisfy that property P whatever. So, A satisfies P that is necessary. Then take any other subset which satisfy P , suppose B also satisfies P ok? then A cannot be properly contained inside B . A must be the biggest, A must be the maximal that is the meaning of this. So, if B also satisfies, and A subset of B then A must be equal to B .

A is contained inside B and B is also satisfy this, A must be equal to B this just means that if I take slightly larger subset, strictly larger subset, then it will not satisfy P ok. So, this property P must be for subsets of a topological space X that is the whole idea because it is a topological property. So, whereas, this definition is for all, this is just set theoretic definition, there is no topology here.

(Refer Slide Time: 11:04)

The screenshot shows a presentation slide with a table of contents at the top, a video feed of a speaker, and a main text area. The table of contents lists modules from 36 to 46. The video feed shows a man with glasses and a white beard. The main text area contains the following text:

Example 3.27

For instance, take a topological space X and take P to be the property of being connected. Then a subset A of X is maximal with respect to P means that A is a connected of X such that any subset of X larger than A will not be connected. Similarly, we can define maximal path connected subsets of X .

At the bottom of the slide, there is a footer with the NPTEL logo, the name of the speaker (Anand R Shastri), his title (Retired Emeritus Fellow Department of Mathematics), the course name (NPTEL NDC An Introductory Course on Point-Set Topology), and the current module (Module 32 Path Connectivity).

Now, we are going to make it a topological property especially take P to be the property of being connected. In other words, look at all subsets of X , collect all of them which are connected into a family of subsets of the set X .

Now, you take a maximal element A in this collection ok that means, anything every element here is connected first of all and anything slightly bigger than A will not be connected ok? That is the meaning of maximal element ok. So, we can make that as our definition now, let us see.

(Refer Slide Time: 12:01)

Theorem 3.28

Let X be a topological space. Then every point $x \in X$ is contained in a maximal connected subset of X . Thus X is the disjoint union of its maximal connected subsets.

Let X be a topological space. Then every point x belonging to X is contained in a maximal connected subset. Thus, X is the disjoint union of its maximal connected subsets.

If I prove the first part, then the second part is purely set theory because every point is in a maximal set. So, union of maximal subsets will be the whole of X . So, we want to prove that each point is contained in a maximal connected subset. To begin with, singleton sets are connected right? So, they are the members of this set of all connected subsets of X alright. I want to show that it is in a maximal set, every x must be in a maximal set that is what I have to show ok.

So, now, use this property to enlarge this single point into a maximal set that is what we want to show, this property we keep using again and again so, here is the way how to do that.

Proof: Define a relation R on X as follows: xRy iff there exists a connected subset T in X such that $x, y \in T$. Clearly R is reflexive and symmetric. Transitivity follows from the previous theorem. Therefore R is an equivalence relation. Suppose C is one of the equivalence classes and $C = A \cup B$. Pick up $a \in A$ and $b \in B$. But then aRb and hence there exists a connected subset T such that $a, b \in T$. But then $T \subset C$. Since T is connected, T should be contained in either A or B , which is absurd. Therefore C is connected. Since equivalence classes form a partition of X , it follows that each of them is a maximal connected set.

Define a relation I am saying here is a way that is not just this is the only way, there are many ways for example, you can use Zorn's lemma and so on, I do not want to use Zorn's lemma. I want to do this in a very elementary way.

Define a relation R on X as follows: x is related to y if and only if there exists a connected subset T inside X to which both x and y belong; both x and y belong to T .

Singleton sets are connected and so this relation is reflexive. Take T as singleton the singleton $\{x\}$ then x is related to x . If x is related to y , then x and y are both inside T . So, y is also related to x . Transitivity needs some proof but that is precisely what we saw in the previous theorem.

If T_1 is containing x and y and T_2 is containing y and z , then what happens $T_1 \cup T_2$ will be connected because both of them have a common point y . T_1 and T_2 are connected, they have a common point so, union is connected is a previous theorem. So, I have found a connected set which contains x and z ok? So, transitivity follows from the previous theorem.

Therefore, this R is an equivalence relation. As soon as you have an equivalence relation, you have a partition. Then, this is the second part was precisely a partition, what is partition here?

X is the disjoint union of maximal connected subsets. So, each member of a partition is a maximal connected subset. So, that part directly I am proving here ok? That will give you that every point is inside a maximal connected subset.

So, these equivalence classes I have to show, are connected, and they cannot be bigger. If you put any more point, it will be disconnected that is the maximality ok. To show that it is connected, take an equivalence class C ok? Suppose there is a partition, $C = A|B$. Pick up an element $a \in A$ and $b \in B$ ok, but they are in the same class which means a is related to b and hence, there is a common connected set T which contain both a and b right, but since T be connected it should be either in A or in B that is a contradiction, because one point is inside A another point is inside B ok?

(THIS IS IRRELEVANT AND A REPETITION).

Therefore, C is connected and there is no separation like this, there is no separation like this ok. Therefore, each equivalence class is connected right, equivalence classes are already define a partition of X . So, anything bigger than that cannot be connected, but a set which is bigger is not an equivalence class. It is a bigger class right so, these are actually maximal connected sets.

(Refer Slide Time: 18:05)

The image shows a presentation slide with a table of contents at the top and a definition box in the middle. The table of contents lists modules 38 through 46. The definition box, titled 'Definition 3.29', states: 'A maximal connected subset of X is called a **connected component**. Often, we omit the term 'connected' and merely use the term 'component' to mean a connected component.'

--	---

Definition 3.29

A maximal connected subset of X is called a **connected component**. Often, we omit the term 'connected' and merely use the term 'component' to mean a connected component.

Arund R Shastri Retired Emeritus Fellow Department of Mathematics NPTEL-NOI An Introductory Course on Point-Set Topology. I

Module-32 Path Connectivity
 Module-36 Local connectivity and local path connectivity

So, it is better to give a name for this maximal connected sets. After all, all the time you will have to keep on saying maximal connected, maximal connected. So, such things are called connected components and quite often when you are discussing connectivity, you will just say component that is the whole idea of naming this I mean this definition is just for the namesake precisely I mean literally it is for namesake ok.

(Refer Slide Time: 18:42)

The screenshot shows a video lecture interface. At the top, there are two navigation bars. The left bar lists: 'Topological Groups and Topological Vector Spaces'. The right bar lists: 'Module 41: Countability and Separability', 'Module 42: Types of Topological Properties', 'Module 43: Productive Properties', and 'Module 46: Alexander's Subbase Theorem'. A small video window in the top right shows a man with glasses and a beard, identified as 'Anant Shastri'. The main content area features a blue header 'Theorem 3.30' followed by the text: 'Let $Z \subset X$ be a connected subset. Then \bar{Z} is connected. In particular, each connected component of X is a closed subset of X .' Below this is the proof: 'Proof: Assume $\bar{Z} = A \cup B$. From theorem 3.28, we have, $Z \subset A$ or $Z \subset B$, say, $Z \subset A$. But then since A is a closed set, it follows that $\bar{Z} \subset A$, a contradiction. The last part follows because of the maximality of connected components.' At the bottom, another navigation bar shows: 'Anant R Shastri Retired Emeritus Fellow Department of Mathematics', 'NPTEL-NOC An Introductory Course on Point-Set Topology, I', and a list of modules including 'Module 32 Path Connectivity', 'Module 35 Local connectivity and local path connectivity', 'Module 36 Compactness and Lindelöfness', and 'Module 39 Compact Metric Spaces'. The NPTEL logo is visible in the bottom left corner.

Let Z contained inside X be a connected subset. Then, the closure is connected. Now, why we are having such a thing you see? Now, we want to understand what happens to connected components, they are already giving you a partition of the whole space. Now, this theorem says that take a connected component, closure is automatically larger, but it cannot be larger, it has to be equal because the closure is also connected subset. Z being connected component, anything bigger cannot be connected therefore, there must be equality.

So, this theorem tells you immediately that connected components are closed inside the original space X ok? So, let us prove that \bar{Z} is connected. Assume \bar{Z} has a separation A, B ok separation, but then Z is connected so, Z is inside A or inside B . Remember if A is closed, Z is contained inside A , then \bar{Z} is contained inside A , this was our old result about closures. Therefore, \bar{Z} is either inside A or inside B , ok. So, there is no such separation.

So, you see several of these results we have been deducing by contradiction. Why because the connectivity itself is in that form, that is what I meant by it is some kind of a negative definition ok.

(Refer Slide Time: 20:43)

The screenshot shows a video lecture interface. At the top, there is a header with the name 'Anand R Shastri' and the course title 'NPTEL-NOC An Introductory Course on Point-Set Topology, I'. Below this is a table of contents with two columns. The left column lists: Introduction, Creating New Spaces, Smallest Properties of Topological Spaces, Separation Axioms, and Topological Groups and Topological Vector Spaces. The right column lists: Module-32 Path Connectivity, Module-33 Local connectivity and local path connectivity, Module-34 Compactness and Lindelöfness, Module-35 Compact Metric Spaces, Module-41 Countability and Separability, Module-42 Types of Topological Properties, Module-43 Productive Properties, and Module-46 Alexander's Subbase Theorem. To the right of the table of contents is a small video window showing the lecturer, Anand R Shastri. Below the table of contents is a slide titled 'Remark 3.31' which contains the following text: 'Path connected components are also defined in the same fashion. However, in the case of path (connected) components, a more intrinsic description is possible, viz, via the equivalence relation $x \sim y$ iff there is a path in X from x to y .' At the bottom left of the slide is the NPTEL logo.

Path connected components are also defined in the same fashion, what is it? Maximal path connected subsets of a given topological space ok. So, you can also say that they equivalence classes where the equivalence relation is that x is related to y if and only if there is a path from x to y . No need to have that path connected subset and so on, the image of a path is already a path connected space. So, this is slightly easier to digest, this equivalence relation.

In fact, usually whatever happens to path connected space you can try to copy it for connected spaces if it works it works so, that is the way that perhaps this theorem has been used here, this definition has been obtained ok. So, path connected components also give you partition of the whole space ok. However, one has to be very careful when you keep saying it is same thing, same thing, same thing. There is lot of close relationship, but but they are after all different notions so, somewhere they will be different. So, that is what you have to be careful about.

Theorem 3.32

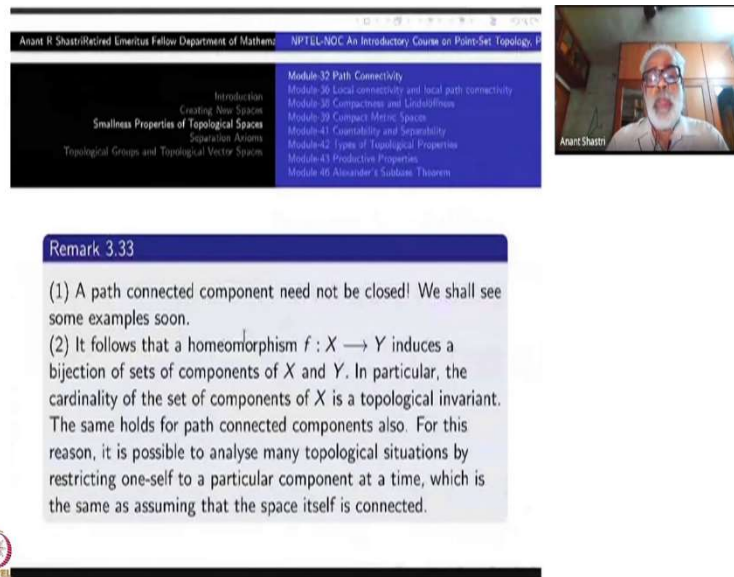

Let X be a topological space, and $x \in X$. Then the set of all points of X which can be joined to x in X is the unique maximal path connected subset of X containing the point x .

The proof is easy and we implore you to write down the details.

NPTEL

Let X be a topological space and x be any point in X . Then the set of all points of X which can be joined to x in X is the unique maximal path connected subset of X containing that point. So, this is another description of path connected components. Start at any point in a space, look at all those points which can be joined to that ok so, that has to be obviously, that is path connected, that has to be the component. If there is another point that can be also joined so, it is already there that is all, very very easy to look at this way ok. So, there is no need to write down formally the proofs of this one.

Remark 3.33

- (1) A path connected component need not be closed! We shall see some examples soon.
- (2) It follows that a homeomorphism $f : X \rightarrow Y$ induces a bijection of sets of components of X and Y . In particular, the cardinality of the set of components of X is a topological invariant. The same holds for path connected components also. For this reason, it is possible to analyse many topological situations by restricting one-self to a particular component at a time, which is the same as assuming that the space itself is connected.

This is where I want to caution you that path connected component need not be closed. In other words, if Z is path connected, \bar{Z} may not be path connected. If that was the case, then components would have been closed. So, we will see an example little later ok.

Secondly, if you have a homeomorphism from X to Y , then look at the path connected components of X ok, they will go in one-to-one fashion to path connected components of Y . Exactly, the components of X , connected components of X , they will go in one one fashion to connected components of Y ok.

In general, path connected components are connected also that we have seen right, but number of path connected components may be larger than the number of connected components, but this correspondence is true for both of them ok. Therefore, what happens is suppose you want to analyze a homeomorphism limit arbitrary X and Y and something, you can do that by component wise restrict f to one component here, when you go to the image, it will be another component there.

Therefore, right in the beginning you can assume that both X and Y are connected by restricting the whole thing to a connected component ok. So, this is how I already told this one, but I have repeated it now again alright. So, next time we will make it sure that you will

be able to see a counter example also for this. In any case, we have a lot of work to do about connectivity alright. Simultaneously whenever such things are true for path connectivity, we will keep uh informing you or we will keep pointing out to you that is all ok.

So, until next time so, let us stop here.
