Lecture-09
Linear System: Gaussian Elimination Method

Hi, in today's class, we will start with a new chapter on numerical linear algebra. In this chapter, we will learn to develop methods for linear systems and also we learn to develop methods for computing some eigenvalues and eigenvectors of a given matrix. In today's class, we will take a linear system. In linear systems, we have 2 classes of methods, one is the direct methods and another class is the iterative methods.

Direct methods are those, which gives us exact solutions when there is no rounding error is involved. On the other hand, an iterative method gives us a sequence of vectors, which is expected to converge to the solution of the corresponding linear system. In this class, we will start with direct methods for linear systems. In this, first we will learn Gaussian elimination method. Before getting into the method, let us quickly recall what is mean by linear systems and when we can have a unique solution for a linear system?

(Refer Slide Time: 01:51)

As you know, a linear system consists of some n number of equations, which are linear in its unknown and it is given like this $a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$ that is the first equation. Similarly, the second equation and so on. Here a_{ij} 's and b_i are known to us and we are interested in finding the x_i 's.

(Refer Slide Time: 02:37)

General Form of Linear System (contd.)

These equations can be written in the matrix notation as

$$\begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \\ \vdots \\ b_n \end{pmatrix}$$

The last equation is usually written in the following short form

$$Ax = b,$$

where

- A stands for the $n \times n$ matrix with entries a_{ij} ,
- $\mathbf{x} = (x_1, x_2, \dots, x_n)^T$
- the right hand side vector $\mathbf{b} = (b_1, b_2, \dots, b_n)^T$.

We can write this system in a matrix form, where you have the coefficient matrix a_{11}, a_{12} and so on. And you have the unknown vector x_1, x_2, \dots, x_n written in the column form and that is equal to the right hand side vector b_1, b_2, \dots, b_n , which is also written in the column form. As I told the matrix A and B are given to us and x is to be obtained. As you know we can write it as $Ax = b$, where A is this matrix and x is this column vector and the vector b is this column vector.

(Refer Slide Time: 03:40)

General Form of Linear System (contd.)

Let us now state a result concerning the solvability of the system

$$Ax = b.$$

Theorem

Let A be an $n \times n$ matrix and $\mathbf{b} \in \mathbb{R}^n$. Then the following statements concerning the system of linear equations $A\mathbf{x} = \mathbf{b}$ are equivalent.

- $\det(A) \neq 0$
- For each right hand side vector \mathbf{b} , the system $A\mathbf{x} = \mathbf{b}$ has a unique solution \mathbf{x} .
- For $\mathbf{b} = \mathbf{0}$, the only solution of the system $A\mathbf{x} = \mathbf{b}$ is $\mathbf{x} = \mathbf{0}$.

Let us now see when the system $Ax = b$ is solvable. Well, we have a very well known theorem studied at our basic course on linear algebra, let us recall here without proof. You are given a $n \times n$ matrix A and the right hand side vector b . Then the following statements are equivalent

for the system $Ax = b$, that is you have determinant of A is not equal to 0 and for any given right hand side vector b , the system $Ax = b$ has a unique solution x .

So, it means you expect a unique solution for your linear system, if and only if determinant of A is not equal to zero, that is A is an invertible matrix. And you can also prove the equivalence of these 2 statements with the statement that if you take $b = 0$ in particular, then the only solution of the system $Ax = 0$, is the zero vector. We will not go to prove this theorem, because it is the part of linear algebra course.

Interested students can go and take any linear algebra book and recall the proof of this theorem. We will only keep this theorem in mind and assume from now onwards, that any matrix that we work with, is an invertible matrix.

(Refer Slide Time: 05:34)

Linear Systems: Naive Gaussian Elimination Method

Carl Friedrich Gauss (1777-1855) *German mathematician*

Consider the following system:

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 && E_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 && E_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3 && E_3 \end{aligned}$$

Upper triangular System

Handwritten notes: Step 1, Step 2, $E_2 - \frac{a_{21}}{a_{11}} \times E_1$

The first method, that we are going to learn is the well-known Gaussian elimination method, it is introduced by a German mathematician Carl Friedrich Gauss. The basic idea of Gaussian elimination method is to take the given system and convert it into an upper triangular system by applying certain elementary row operations. Once you have the upper triangular system, it is direct for us to get the solution of that upper triangular system, through a backward substitution process.

As we know from our elementary linear algebra course, the solution of the given system is equivalent to any system that is obtained through certain elementary row operations. The upper triangular system's solution will be the solution of our original system. That is how we obtain

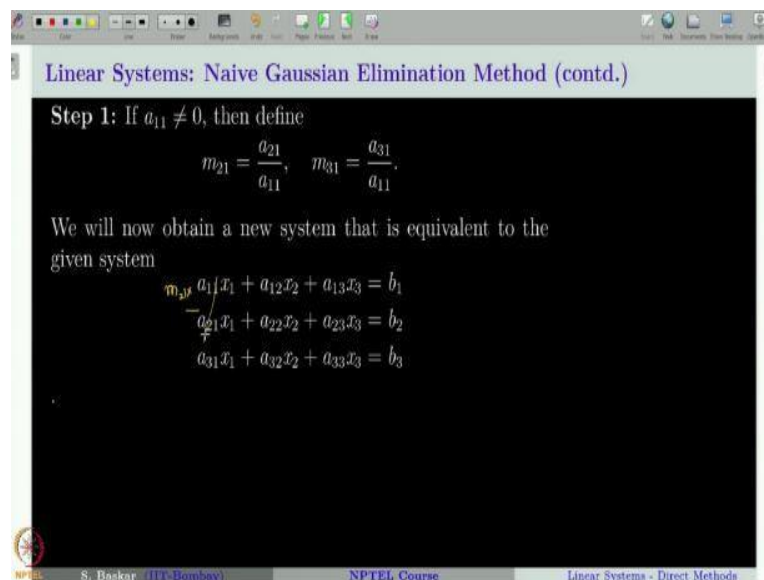

the solution of our original system. Let us only consider 3×3 system and try to understand the Gaussian elimination method.

And the method for any $n \times n$ system can be generalized, very easily and in a very similar way. Once we understand this method for 3×3 systems. Now, how are we going to achieve this upper triangular system, well we will go through in steps. In the first step, we will try to make this coefficient as 0 and this coefficient as 0. So, that will give us the first step. Once we achieve the first step, then we will go to make this coefficient to be 0 in the second step.

Whereas, the first one this is achieved in the first step, then you have an upper triangular system. So, how are we going to do? You can clearly see that you take $\frac{a_{21}}{a_{11}}$ and multiply it with the first equation. Let us call this as E_1 , this as E_2 and this as E_3 and then you subtract E_2 with this equation this is going to be E_1 . So, you multiply the first equation with this number and then subtract the second equation with the first equation.

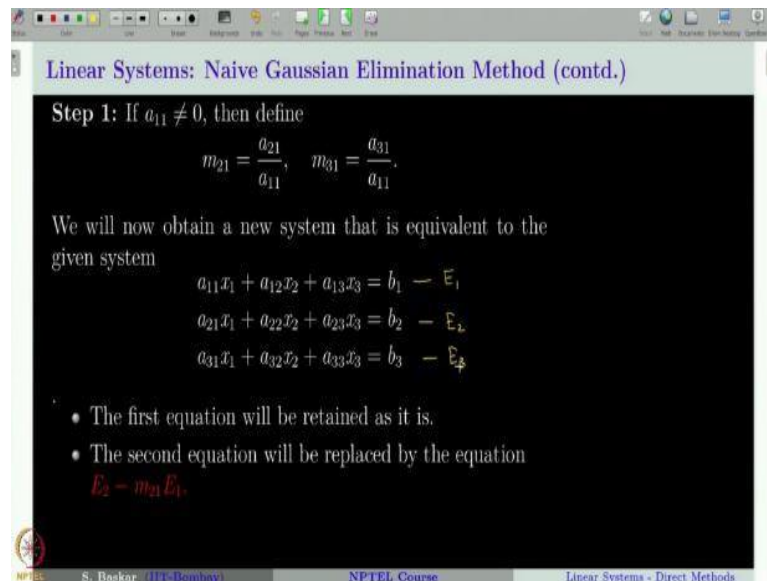

That will make this term to be 0, this term, that is the idea. Similarly, you can make the other the coefficient of x_1 in the third equation also as 0. Let us make this idea more precise.

(Refer Slide Time: 09:02)

You can see that for this we need a_{11} to be non zero, otherwise you just cannot go ahead with this idea. So, if a_{11} is not equal to 0, then define $m_{21} = \frac{a_{21}}{a_{11}}$ and similarly $m_{31} = \frac{a_{31}}{a_{11}}$. And now as I told you multiply this first equation with m_{21} and then you take that and subtract with this second equation and that will obviously make the first term to get canceled. So, that is the idea.

(Refer Slide Time: 09:53)

Linear Systems: Naive Gaussian Elimination Method (contd.)

Step 1: If $a_{11} \neq 0$, then define

$$m_{21} = \frac{a_{21}}{a_{11}}, \quad m_{31} = \frac{a_{31}}{a_{11}}$$

We will now obtain a new system that is equivalent to the given system

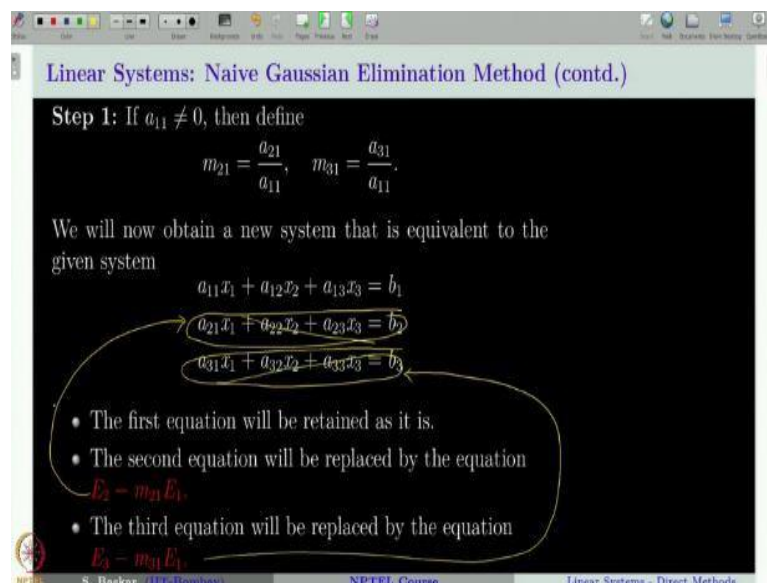

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 & - E_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 & - E_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3 & - E_3 \end{aligned}$$

- The first equation will be retained as it is.
- The second equation will be replaced by the equation $E_2 - m_{21}E_1$.

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

Now, what we will do for getting our reduced system. In step 1, we have to first retain the equation 1 as it is. Then, do the operation $E_2 - m_{21}E_1$. Just recall, we are calling this as E_1 , E_2 and E_3 . And then you go to do the third equation with $E_3 - m_{31}E_1$.

(Refer Slide Time: 10:42)

Linear Systems: Naive Gaussian Elimination Method (contd.)

Step 1: If $a_{11} \neq 0$, then define

$$m_{21} = \frac{a_{21}}{a_{11}}, \quad m_{31} = \frac{a_{31}}{a_{11}}$$

We will now obtain a new system that is equivalent to the given system

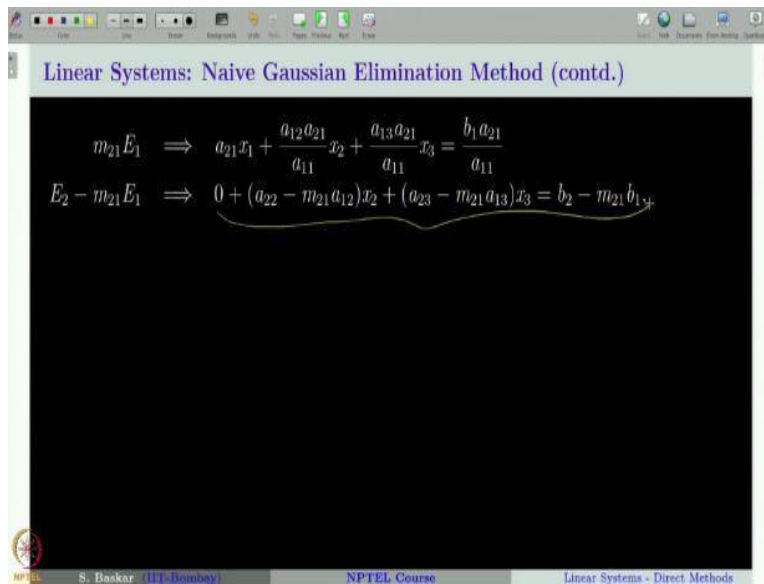

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3 \end{aligned}$$

- The first equation will be retained as it is.
- The second equation will be replaced by the equation $E_2 - m_{21}E_1$.
- The third equation will be replaced by the equation $E_3 - m_{31}E_1$.

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

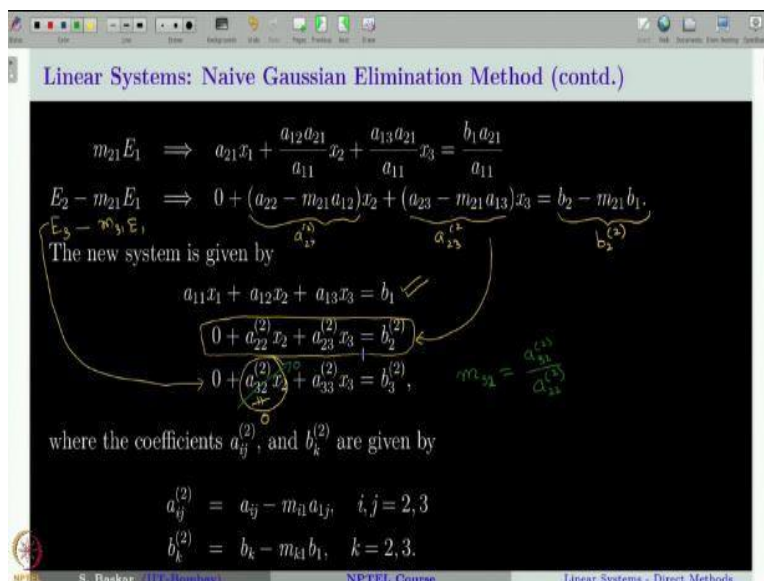

Now, what you do you remove this equation and put this equation here. Similarly, you remove this equation and put this equation here that gives you the reduced system at the level 1.

(Refer Slide Time: 10:56)

So, I am just showing you the calculations you can do it very easily. So, the second equation will look like this and that will now be replaced with the second equation of our given system.

(Refer Slide Time: 11:06)

So, we will call this term as $a_{22}^{(2)}$ and this as $a_{23}^{(2)}$. Remember correspondingly the right hand side vector will also change and we will call it as $b_2^{(2)}$ and that is what we are doing, we are removing our second equation and retaining this equation here, whereas the first equation is retained as it is. In a similar way, you can also compute $E_3 - m_{31}E_1$ and you replace that here instead of the third equation in the original system.

So, that gives you the reduced system in the first step, remember this is still not the upper triangular matrix, because this term may not have zero coefficient, that is $a_{32}^{(2)}$ may not be 0. If

it is 0 you can just stop it at this level itself. If this is not equal to 0 then you go for the second step, where the idea is exactly the same you have to eliminate this term. So, for this you will use what we will call as m_{32} and that is nothing but $\frac{a_{32}^{(2)}}{a_{22}^{(2)}}$ and then you will multiply it with the second equation and then subtract the third equation with the second equation.

(Refer Slide Time: 13:04)

Naive Gaussian Elimination Method (contd.)

Step 2: If $a_{22}^{(2)} \neq 0$, then define $m_{32} = \frac{a_{32}^{(2)}}{a_{22}^{(2)}}$.

We will now obtain a new system that is equivalent to the system

$$\begin{pmatrix} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 = b_1 \\ 0 + a_{22}^{(2)}x_2 + a_{23}^{(2)}x_3 = b_2^{(2)} \\ 0 + a_{32}^{(2)}x_2 + a_{33}^{(2)}x_3 = b_3^{(2)} \end{pmatrix}$$

as follows:

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

That is, you define $m_{32} = \frac{a_{32}^{(2)}}{a_{22}^{(2)}}$ provided if $a_{22}^{(2)}$ is not equal to 0. If $a_{22}^{(2)}$ is 0, then again your Gaussian elimination method will fail at this level. Once you have this, you multiply that with the second equation m_{32} and then subtracted with this equation.

(Refer Slide Time: 13:41)

Naive Gaussian Elimination Method (contd.)

Step 2: If $a_{22}^{(2)} \neq 0$, then define $m_{32} = \frac{a_{32}^{(2)}}{a_{22}^{(2)}}$.

We will now obtain a new system that is equivalent to the system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 && \text{--- } E_1 \\ 0 + a_{22}^{(2)}x_2 + a_{23}^{(2)}x_3 &= b_2^{(2)} && \text{--- } E_2 \\ 0 + a_{32}^{(2)}x_2 + a_{33}^{(2)}x_3 &= b_3^{(2)} && \text{--- } E_3 \end{aligned}$$

as follows:

- The first two equations are retained.
- The third equation will be replaced by the equation $E_3 - m_{32}E_2$.

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

So, again what are the all the process that we have to do at this level? Well, the first 2 equations are retained now. Remember in step one, first equation was retained. Now we have to retain the first 2 equations keep the upper triangular structure in mind and see this. And then the third equation will be replaced by E_3 we are still calling it as E_3 and this as E_2 and this as E_1 . So, $E_3 - m_{32}E_2$ that is replaced by the third equation of this step, that is this equation will be replaced now by this equation.

(Refer Slide Time: 14:24)

Naive Gaussian Elimination Method (contd.)

Note the new system is given by

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ 0 + a_{22}^{(2)}x_2 + a_{23}^{(2)}x_3 &= b_2^{(2)} \\ 0 + 0 + a_{33}^{(3)}x_3 &= b_3^{(3)}, \end{aligned}$$

where the coefficient $a_{33}^{(3)}$, and $b_3^{(3)}$ are given by

$$\begin{aligned} a_{33}^{(3)} &= a_{33}^{(2)} - m_{32}a_{23}^{(2)}, \\ b_3^{(3)} &= b_3^{(2)} - m_{32}b_2^{(2)}. \end{aligned}$$

This phase is called **Forward elimination phase.**

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

That will give us the upper triangular matrix. Well, if it is a 4×4 system then you have to go in a similar way for one more step and 5×5 system means 2 more steps and so on. But the idea is same that is why we are just taking the 3×3 system and understanding the method. Once you understand it, any dimension can be generalized in a similar way. Now, you see you have only the upper triangular system here.

Now, from here we have to get the solution for this upper triangular system, which will be the same as the solution of our original system also and this phase is called the forward elimination phase.

(Refer Slide Time: 15:23)

Naive Gaussian Elimination Method (contd.)

Finally, we obtained the system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ 0 + a_{22}^{(2)}x_2 + a_{23}^{(2)}x_3 &= b_2^{(2)} \iff \text{Given system} \\ 0 + 0 + a_{33}^{(3)}x_3 &= b_3^{(3)}, \end{aligned}$$

- $a_{33}^{(3)} \neq 0 \Rightarrow x_3 = \frac{b_3^{(3)}}{a_{33}^{(3)}}$

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

Now, as we remarked earlier the solution of this system is going to be equivalent to the solution of the given system. Now, what you do is if $a_{33}^{(3)}$ is not equal to 0 we can write $x_3 = \frac{b_3^{(3)}}{a_{33}^{(3)}}$.

(Refer Slide Time: 15:59)

Naive Gaussian Elimination Method (contd.)

Finally, we obtained the system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ 0 + a_{22}^{(2)}x_2 + a_{23}^{(2)}x_3 &= b_2^{(2)} \iff \text{Given system} \\ 0 + 0 + a_{33}^{(3)}x_3 &= b_3^{(3)}, \end{aligned}$$

- $a_{33}^{(3)} \neq 0 \Rightarrow x_3$
- Put x_3 in (E_2) gives x_2
- Put x_1 and x_2 in (E_1) gives x_1 .

This solution phase is called **Backward substitution phase.**

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

So, you got x_3 once you have x_3 you can put that value into the second equation, that is this equation, because you can put this value and get x_2 directly, that is the idea. And once you have x_3 and x_2 , this is x_3 then you can put these 2 values that is x_2 and x_3 you substitute and get x_1 . So, that is the backward substitution phase. Therefore, Gaussian elimination method has 2 phases, one is the forward elimination process and other one is the backward substitution process and we call this method as name Gaussian elimination method.

(Refer Slide Time: 16:52)

Naive Gaussian Elimination Method (contd.)

Gaussian elimination \Rightarrow LU-factorization.

$$U = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ 0 & a_{22}^{(2)} & a_{23}^{(2)} \\ 0 & 0 & a_{33}^{(3)} \end{pmatrix}.$$

Define a lower triangular matrix L by

$$L = \begin{pmatrix} 1 & 0 & 0 \\ m_{21} & 1 & 0 \\ m_{31} & m_{32} & 1 \end{pmatrix}.$$

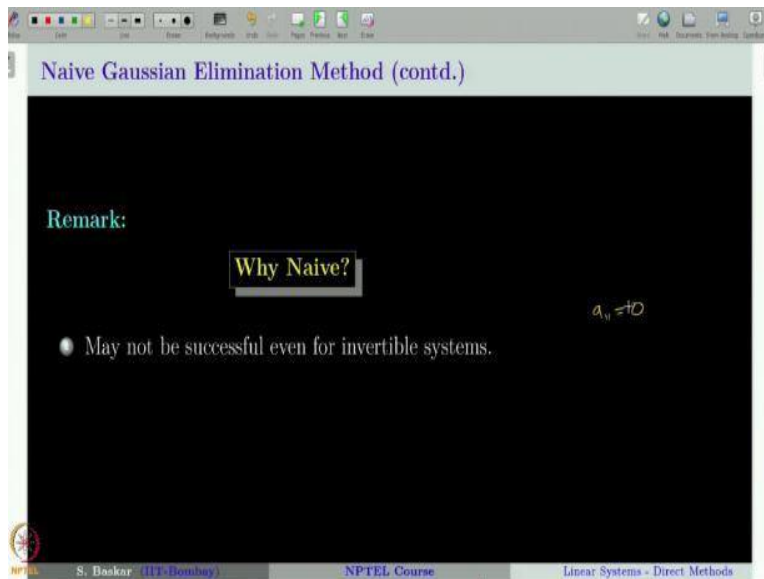

It is easy to verify that $LU = A$.

S. Baskar (IIT-Delhi) NPTEL Course Linear Systems - Direct Methods

Just to remark, Gaussian elimination method can also give rise to a LU-factorization of a given coefficient matrix very naturally, where the upper triangular matrix is precisely the matrix, which comes out of our final eliminated system. And you take the lower triangular matrix as $\begin{pmatrix} 1 & 0 & 0 \\ 0 & m_{21} & 0 \\ 0 & 0 & 1 \end{pmatrix}$ is the number we calculated in step 1. Now you can write your matrix $A = LU$. That is what is called LU-factorization of a matrix A .

It means, you will find the upper triangular matrix under lower triangular matrix and write A as the product of the lower triangular matrix and the upper triangular matrix. And Gaussian elimination method gives the LU-factorization of a given matrix. This is just a remark here; it is nothing to do with the Gaussian elimination method. However, in our next section we will be learning LU-factorization, where we will be learning some other methods to do this LU-factorization. Here, I am just remarking that Gaussian elimination method is also one of those methods.

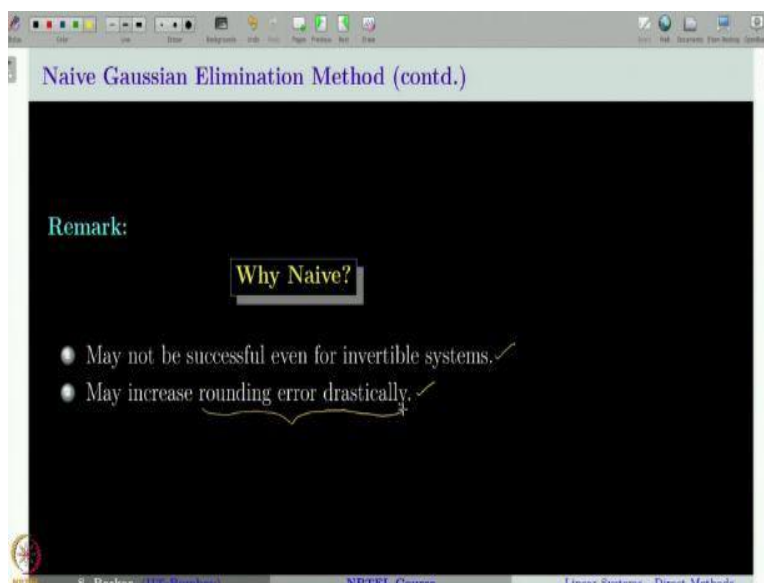

(Refer Slide Time: 18:18)

Now, coming to the question of why are we putting this special name, Naive Gaussian elimination method why that word naive came here? Well, there are 2 reasons for that. One is the method may not work always even if you have invertible system. For instance, if you have the matrix A , which is nice invertible but if $a_{11} = 0$ you cannot even start the method, because to define m_{21} and m_{22} we need a_{11} to be not equal to zero, because they are sitting in the denominator.

Therefore, if a_{11} is 0 or in the second step if $a_{22}^{(2)}$ is 0 then also we cannot go ahead with the Gaussian elimination method that is the problem with this method.

(Refer Slide Time: 19:19)

And another one is that this method will increase the rounding error drastically. There are other ways to make the method work, which is called the partial pivoting idea that we will come in

the next discussion, but as we explained the Gaussian elimination method these are the inbuilt problems in the method that is why we call this method as Naive Gaussian elimination method. Let us give an example to get a feeling of how the name Gaussian elimination method can increase the rounding error drastically and spoil the accuracy of the solution.

(Refer Slide Time: 20:09)

Naive Gaussian Elimination Method (contd.)

Example:

Consider the linear system

$$\begin{aligned} 6x_1 + 2x_2 + 2x_3 &= -2 \\ 2x_1 + \frac{2}{3}x_2 + \frac{1}{3}x_3 &= 1 \\ x_1 + 2x_2 - x_3 &= 0. \end{aligned}$$

Let us compute using 4-digit rounding.

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

For this let us take this system of 3 equations, where in the second equation you have the term $\frac{2}{3}x_2$ and $\frac{1}{3}x_3$. Remember, these 2 numbers when written in the floating-point representation has infinitely many digits in the mantissa. Now, we will try to calculate the solution of this system using Naive Gaussian elimination method and we will involve 4-digits rounding in our calculation.

Remember, from our previous lectures how to do calculations with floating-point approximation. Every step, every single operation is done you have to do a floating-point approximation of the resulting number. Like that the calculations should be carried over. Here, the floating-point approximation is using 4-digits rounding.

(Refer Slide Time: 21:13)

Naive Gaussian Elimination Method (contd.)

The system to be solved is

$$\begin{aligned} 6.000x_1 + 2.000x_2 + 2.000x_3 &= -2.000 \\ 2.000x_1 + 0.6667x_2 + 0.3333x_3 &= 1.000 \\ 1.000x_1 + 2.000x_2 - 1.000x_3 &= 0.000 \end{aligned}$$

After eliminating x_1 from the second and third equations, we get (with $m_{21} = 0.3333$, $m_{31} = 0.1667$).

$$\begin{aligned} 6.000x_1 + 2.000x_2 + 2.000x_3 &= -2.000 \\ 0.000x_1 + 0.0001x_2 - 0.3333x_3 &= 1.667 \\ 0.000x_1 + 1.667x_2 - 1.333x_3 &= 0.3334 \end{aligned}$$

S. Baekar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

Remember, we have to also represent the matrix in the 4-digits rounding, because at all levels whichever number we use whether, it is an input number or the calculated number it has to go with four digits rounding only. Therefore, we will first write the given system in the 4-digits rounding form. Well, all coefficients remain the same there is no approximation involved other than this term and this term.

Just observe that this term has a very big rounding error and after eliminating, you get this system. Here, you notice that you have 0.0001 coming because of this rounding problem.

(Refer Slide Time: 22:17)

Naive Gaussian Elimination Method (contd.)

After eliminating x_2 from the third equation, we get (with $m_{32} = 16670$)

$$\begin{aligned} 6.000x_1 + 2.000x_2 + 2.000x_3 &= -2.000 \\ 0.000x_1 + 0.0001x_2 - 0.3333x_3 &= 1.667 \\ 0.000x_1 + 0.0000x_2 + 5555x_3 &= -27790 \end{aligned}$$

Using back substitution, we get

$$x_1 = 1.335, x_2 = 0 \text{ and } x_3 = -5.003,$$

whereas the actual solution is

$$x_1 = 2.6, x_2 = -3.8 \text{ and } x_3 = -5.$$

Reason?
The coefficient of x_2 in (E_3) should have been zero, but rounding approximation prevented it.

S. Baekar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

And in the second process you can see that you are dividing this number with this number and that will make m_{32} to be a very big number and that results in the coefficient of x_3 very big. You can observe this. This itself, gives us a feeling that something is going wrong here. Let us

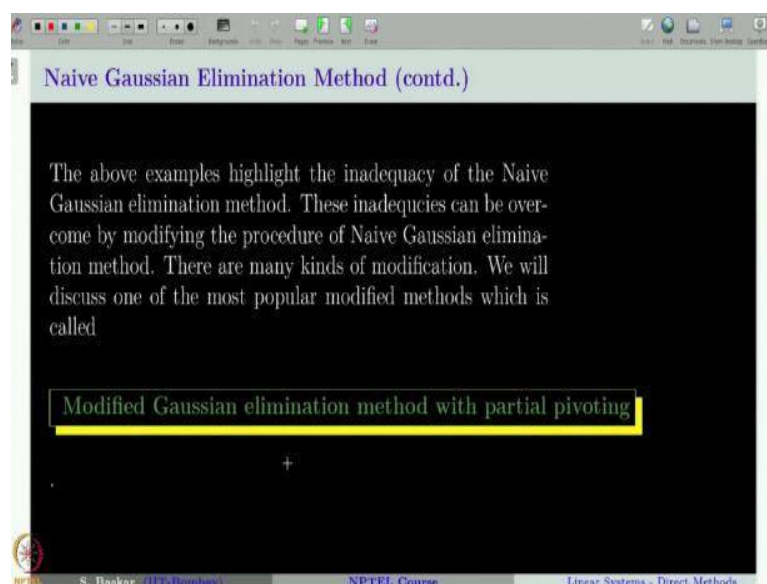

compute the solution, now using the backward substitution phase and the solution finally comes to be this vector.

Now, what is the exact solution? Well, the exact solution computed with infinite precision this can be done by just keeping the terms in the fractional form itself, without doing any rounding or you can simply do the rounding with very high precision so, like double precision and all. Then also you will get a pretty close solution, when compared to the exact solution.

So, here the exact solution is given like this and our approximate solution is this. You can see that the component x_1 and x_2 are no way close to the exact solution. So, that is the danger of the rounding error into any method in particular Naive Gaussian elimination method, where is very sensitive to rounding errors. What is the reason for this drastic amplification of the error? Well, I have already told, that this is precisely, because you are trying to divide this term by this one.

In the original system that is if you are making this calculation without any error then this would have been 0, but because of the rounding error this is non-zero and that amplified the error drastically. Otherwise, the name Gaussian elimination method would have failed at the second step itself. But, now it went on and found a bad solution.

(Refer Slide Time: 24:39)

How to get rid of all these problems in the Naive Gaussian elimination method? Well, that is using an idea called partial pivoting and we call the method as modified Gaussian elimination method with partial pivoting. We can also do full pivoting, but that will be very expensive

when compared to partial pivoting and the accuracy that we achieve in full pivoting is not that good improvement when compared to the partial pivoting.

Also once you understand the partial pivoting idea, you can do the full pivoting without much difficulty in understanding the method. Therefore, in our course we will introduce only partial pivoting and we will not discuss the full pivoting technique. Let us go to see what is mean by partial pivoting?

(Refer Slide Time: 25:35)

Modified Gaussian elimination method with partial pivoting

Consider the following system of three linear equations in three variables x_1, x_2, x_3 :

$$\begin{aligned} &\rightarrow a_{11}x_1 + a_{12}x_2 + a_{13}x_3 = b_1 \\ &\rightarrow a_{21}x_1 + a_{22}x_2 + a_{23}x_3 = b_2 \\ &\rightarrow a_{31}x_1 + a_{32}x_2 + a_{33}x_3 = b_3. \end{aligned}$$

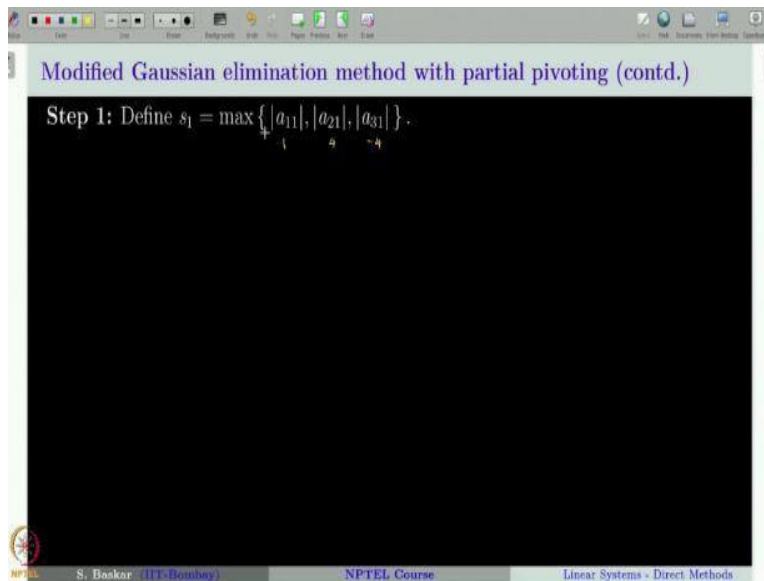

For convenience, we call the first, second, and third equations by names E_1, E_2 , and E_3 respectively.

S. Bankar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

So, you are given the system again, we will consider only 3×3 system and try to understand the method and generalizing it to any $n \times n$ system is very easy and direct. The only difference in the partial pivoting is that you take the column at which you are going to do the elimination process for instance, in step 1 you are going to do the elimination process for these 2 terms.

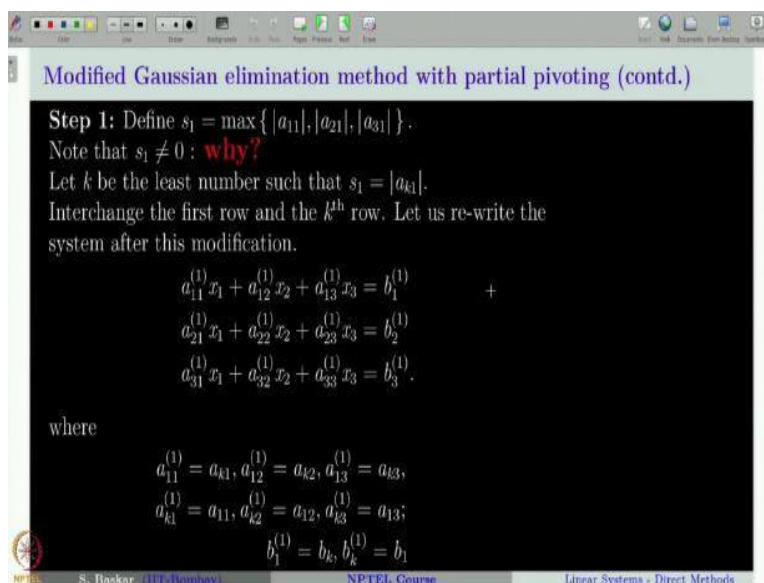

Therefore, you take this column and find the maximum of the absolute values of this. These coefficients and then whichever attains the maximum you replace that equation with the first equation that is the idea.

(Refer Slide Time: 26:30)

Let us take a_{11} , a_{21} and a_{31} . Say for instance this is 1 and this is say 4 and this is -4. Then you will have 1, 4 and 4. The maximum will be therefore 4.

(Refer Slide Time: 26:48)

And you can in fact see that s_1 will never be zero; I leave it to you to think why it is? The reason is that we are always working with invertible matrix. Now, you pick up that component at which the maximum is attained with the lowest index. For instance, in our example we have taken 2, 4 and -4 as the coefficients. Therefore, your modulus will be 2, 4 and 4 and the maximum is achieved in these 2 coefficients.

However, we will take only the least one that is a_{21} we will take. This is just to make the algorithm more precise, it does not matter whichever, you take. But, for the algorithm sake we will take the least one. And you have to interchange that k th row with the first row. And let us

call the new system after interchanging with the superscript 1. In this case suppose if the maximum is achieved at the second equation, then from the original system you push the second equation to the first equation and the first equation to the second equation.

(Refer Slide Time: 28:11)

Now eliminate the x_1 variable from the second and third equations of the system

$$\begin{aligned} a_{11}^{(1)} x_1 + a_{12}^{(1)} x_2 + a_{13}^{(1)} x_3 &= b_1^{(1)} & + \\ a_{21}^{(1)} x_1 + a_{22}^{(1)} x_2 + a_{23}^{(1)} x_3 &= b_2^{(1)} \\ a_{31}^{(1)} x_1 + a_{32}^{(1)} x_2 + a_{33}^{(1)} x_3 &= b_3^{(1)}. \end{aligned}$$

Proceed as in naive Gaussian elimination method.

And now your all other elimination process of step 1 will go as we did with the Naive Gaussian elimination method.

(Refer Slide Time: 28:21)

Note the new system is given by

$$\begin{aligned} a_{11}^{(1)} x_1 + a_{12}^{(1)} x_2 + a_{13}^{(1)} x_3 &= b_1^{(1)} \\ 0 + a_{22}^{(2)} x_2 + a_{23}^{(2)} x_3 &= b_2^{(2)} \\ 0 + a_{32}^{(2)} x_2 + a_{33}^{(2)} x_3 &= b_3^{(2)}, \end{aligned}$$

where the coefficients $a_{ij}^{(2)}$, and $b_k^{(2)}$ are given by

$$\begin{aligned} a_{ij}^{(2)} &= a_{ij}^{(1)} - m_{i1} a_{1j}^{(1)}, \quad i, j = 2, 3 \\ b_i^{(2)} &= b_i^{(1)} - m_{i1} b_1^{(1)}, \quad i = 2, 3. \end{aligned}$$

And we will achieve the eliminated system, where these terms become zero. Remember, this is the system after the pivoting is done and then we went for the elimination process. Now what you have to do in order to go for step 2, you take these 2 elements and do the similar partial pivoting.

(Refer Slide Time: 28:47)

Modified Gaussian elimination method with partial pivoting (contd.)

Step 2: Define $s_2 = \max \left\{ |a_{22}^{(2)}|, |a_{32}^{(2)}| \right\}$.

Let l be the least number such that $s_l = |a_{l2}^{(2)}|$.

Interchange the second row and the l^{th} rows. Let us re-write the system after this modification.

$$\begin{aligned} a_{11}^{(1)} x_1 + a_{12}^{(1)} x_2 + a_{13}^{(1)} x_3 &= b_1^{(1)} \\ 0 + a_{22}^{(3)} x_2 + a_{23}^{(3)} x_3 &= b_2^{(3)} \\ 0 + a_{32}^{(3)} x_2 + a_{33}^{(3)} x_3 &= b_3^{(3)}, \end{aligned}$$

where the coefficients $a_{ij}^{(3)}$, and $b_i^{(3)}$ are given by

$$\begin{aligned} a_{22}^{(3)} &= a_{l2}^{(2)}, a_{23}^{(3)} = a_{l3}^{(2)}, a_{12}^{(3)} = a_{22}^{(2)}, a_{13}^{(3)} = a_{23}^{(2)}, \\ b_2^{(3)} &= b_l^{(2)}, b_1^{(3)} = b_2^{(2)} \end{aligned}$$

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

That is you find the maximum between these 2 numbers and then take the one, which achieves the maximum at the least index and call it as l and that l th equation will be now replaced with the second equation. It may be the second equation itself in which case the swapping will not happen. If it is a third equation then third equation will go to the second equation and second will go to the third equation.

And then you call the new pivoted system like this. And then again go for the elimination of this coefficient exactly as we did with the Naive Gaussian elimination method.

(Refer Slide Time: 29:34)

Modified Gaussian elimination method with partial pivoting (contd.)

Note the new system is given by

$$\begin{aligned} +a_{11}^{(1)} x_1 + a_{12}^{(1)} x_2 + a_{13}^{(1)} x_3 &= b_1^{(1)} \\ 0 + a_{22}^{(3)} x_2 + a_{23}^{(3)} x_3 &= b_2^{(3)} \\ 0 + 0 + a_{33}^{(4)} x_3 &= b_3^{(4)}, \end{aligned}$$

where the coefficient $a_{33}^{(4)}$, and $b_3^{(4)}$ are given by

$$\begin{aligned} a_{33}^{(4)} &= a_{33}^{(3)} - m_{32} a_{23}^{(3)}, \\ b_3^{(4)} &= b_3^{(3)} - m_{32} b_2^{(3)}. \end{aligned}$$

Note that the variable x_2 has been eliminated from the last equation.

S. Baskar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

And obtain the upper triangular matrix, in this way the only difference between the modified Gaussian elimination and Naive Gaussian elimination is that we are doing this pivoting step as

a extra step in each of the elimination process, that is the only difference between these 2 methods.

(Refer Slide Time: 29:55)

Modified Gaussian elimination method with partial pivoting (contd.)

The reduced system is

$$\begin{aligned} a_{11}^{(1)}x_1 + a_{12}^{(1)}x_2 + a_{13}^{(1)}x_3 &= b_1^{(1)} \\ 0 + a_{22}^{(3)}x_2 + a_{23}^{(3)}x_3 &= b_2^{(3)} \\ 0 + 0 + a_{33}^{(4)}x_3 &= b_3^{(4)} \end{aligned}$$

Now do the **Backward substitution phase**.

S. Bankar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

Once you have the upper triangular matrix you can go for the backward substitution.

(Refer Slide Time: 30:01)

Modified Gaussian elimination method with partial pivoting (contd.)

Recall the system

$$\begin{aligned} 6x_1 + 2x_2 + 2x_3 &= -2 \\ 2x_1 + \frac{2}{3}x_2 + \frac{1}{3}x_3 &= 1 \\ x_1 + 2x_2 - x_3 &= 0. \end{aligned}$$

was solved using Gaussian Elimination method with four digit rounding arithmetic. Recall the reduced system after Step 1 was

$$\begin{aligned} 6.000x_1 + 2.000x_2 + 2.000x_3 &= -2.000 \\ 0.000x_1 + 0.0001x_2 + 0.3333x_3 &= 1.667 \\ 0.000x_1 + 1.667x_2 - 1.333x_3 &= 0.3334 \end{aligned}$$

0.0001
1.667

S. Bankar (IIT-Bombay) NPTEL Course Linear Systems - Direct Methods

Let us take the example that we did previously. And now you see in the first step you have to take the maximum between 6, 2 and 1. Therefore, the maximum is achieved at the first equation only. Therefore, there is no interchange of equations will happen. And the first step of the modified Gaussian elimination method leads to the same system as what we obtained in the Naive Gaussian elimination method.

Now, you have to do the pivoting among these 2 equations, by checking these 2 coefficients. You can see that the maximum is now achieved at the third equation. Therefore, third equation will go to the second equation and second equation will come to the third equation.

(Refer Slide Time: 30:53)

Modified Gaussian elimination method with partial pivoting (contd.)

The final system is (with $m_{32} = 0.00005999$)

$$\begin{aligned} 6.000x_1 + 2.000x_2 + 2.000x_3 &= -2.000 \\ 0.000x_1 + 1.667x_2 - 1.333x_3 &= 0.3334 \\ 0.000x_1 + 0.0000x_2 - 0.3332x_3 &= 1.667 \end{aligned}$$

with back substitution, we obtain the approximate solution as

$$x_1 = 2.602, x_2 = -3.801 \text{ and } x_3 = -5.003.$$

Recall, the solution obtained without pivoting was

$$x_1 = 1.335, x_2 = 0 \text{ and } x_3 = -5.003,$$

whereas the actual solution is

$$x_1 = 2.6, x_2 = -3.8 \text{ and } x_3 = -5.$$

S. Baskar (IIT Bombay) NPTEL Course Linear Systems - Direct Methods

And once you do the elimination process now you are going to divide 0.0001, because that came to this position divided by 1.667, because that has gone to the second position that will make the process more comfortable and will not magnify the error drastically and therefore your solution is now going to be $x_1 = 2.602$, $x_2 = -3.801$ and x_3 is -5.003 . And you can see that the solution without pivoting that is in our previous example, we obtained this solution.

What is the exact solution? The exact solution is this you can compare these 3 and see that the modified Gaussian elimination method in this example gave a very good approximation to the exact solution than the one with the Naive Gaussian elimination method. Therefore, whatever it is your modified Gaussian elimination method will give you a better approximation to your original system when compared to the Naive Gaussian elimination method. And this is all about the Gaussian elimination method. Thank you for your attention.
