Problems in Sequence of Random Variables (Contd...)

(Refer Slide Time: 00:02)

2) Let X_1, X_2, \dots be a sequence of r.v.s each having CDF

$$F_{X_n}(x) = \begin{cases} 0, & -\infty < x < 0 \\ 1 - \left(1 - \frac{x}{n}\right)^n, & 0 \leq x < n \\ 1, & n \leq x < \infty \end{cases}$$

As $n \rightarrow \infty$

$$F_{X_n}(x) = \begin{cases} 0, & -\infty < x < 0 \\ 1 - e^{-x}, & 0 \leq x < \infty \end{cases}$$

Next example, let x_1, x_2 and so on be a sequence of random variables, each having CDF cumulative distribution function. F suffix x_n of x , it is zero from minus infinity to zero and it takes a value $1 - (1 - x/n)^n$ for x lies between zero to n . From n onwards till infinity the value is 1. So this is the cumulative distribution function for the random variables exercise.

It is a function of n , therefore I have made it F suffix, x suffix n , that means, this is a CDF further random variable n . For every n you have this form. As n tends to infinity, we get F suffix x_n of x , that becomes zero from minus infinity to zero and it takes a value $1 - e^{-x}$ from zero to infinity. As n tends to infinity the CDF of the random variables x_n becomes zero between the interval minus infinity to zero.

And the value becomes $1 - e^{-x}$ where x lies between zero to infinity.

(Refer Slide Time: 02:15)

Suppose X is a r.v. with CDF

$$F_X(x) = \begin{cases} 0, & -\infty < x < 0 \\ 1 - e^{-x}, & 0 \leq x < \infty \end{cases}$$

Then $X_n \xrightarrow{d} X$

$X \sim \text{EXP}(1)$.

Suppose, x is a random variable with the CDF that is f_x of x , that is zero between the interval minus infinity to zero and $1 - e^{-x}$ where x lies between zero to infinity then one can conclude x_n converges to x in distribution since the sequence of x suffix n of x tends to F of x for x is greater than or equal to zero and the value is $1 - e^{-x}$.

Hence, one can conclude the sequence of random variable x_n converges to the random variable x in distribution. Here the x is exponential distribution with a parameter 1. So this is the one example of a how the sequence of random variable converges to a random variable in distribution.

(Refer Slide Time: 03:49)

3) Suppose we choose at random n numbers from the interval $[0, 1]$ with uniform distribution. Let X_i be a random variable describing the i th choice. Then, for $i = 1, 2, \dots$

$$E(X_i) = \int_0^1 x \, dx = \frac{1}{2}.$$

Next I move into the third example, suppose we choose at random n numbers from the interval zero to 1 with a uniform distribution, let X_i be a random variable describing the i th

choice. Then for i is equal to 1, 2, and so on, you can find out what is the expectation of X_i is that is nothing but the integration from zero to 1 x times the probability density function, the probability density function for uniform distribution with a interval zero to 1, that is 1 therefore, x into dx , if you compute the expectation of X_i is going to be 1 by 2.

(Refer Slide Time: 05:49)

The image shows handwritten mathematical work on lined paper. It starts with the formula for the variance of a random variable X_i over the interval [0, 1]:

$$\text{Var}(X_i) = \int_0^1 x^2 dx - \left(\frac{1}{2}\right)^2$$

$$= \frac{1}{3} - \frac{1}{4}$$

$$= \frac{1}{12}$$

Then, it defines the sum $S_n = X_1 + X_2 + \dots + X_n$. Below this, it states the expectation of the sample mean:

$$E\left(\frac{S_n}{n}\right) = \frac{1}{2}$$

Finally, it gives the variance of the sample mean:

$$\text{Var}\left(\frac{S_n}{n}\right) = \frac{1}{12n}$$

Similarly, one can evaluate the variants of X_i that is nothing but zero to 1, x square dx minus the mean square. Expectation of x square minus expectation of x the whole square, so the expectation of x square is zero to 1, x square dx . So if you evaluate this quantity, that is 1 by 3 minus 1 by 4. So if you simplify you will get 1 by 12.

If you remember the formula of variants of a uniformly distributed random variable between the interval a to b , then the variants of x_i , x is nothing but you can get it by substituting the value of a is equal to zero and b is equal to 1, you will get 1 by 12. Let S suffix n be x_1 plus x_2 and so on till x . One can find mean and variants of S because you know the mean n variants of x_i using that you can find out what is the mean of S_n .

But our interest is not the finding the mean of S_n , our interest is to find out the mean of S_n by n . That is basically, suppose X_i are the samples, then S_n divided by n is nothing but the sample mean. So expectation of S_n divided by n that becomes 1 by 2. Similarly, if you calculate variants of S_n by n that becomes 1 divided by 12 times n because the variants of X_i is 1 by 12. So the variants of S_n is a summation of X_i from 1 to n therefore, variants of S_n by n becomes 1 divided by 12 times n .

(Refer Slide Time: 08:17)

For any $\epsilon > 0$, using Chebyshev's inequality

$$P\left\{\left|\frac{S_n}{n} - \frac{1}{2}\right| \geq \epsilon\right\} \leq \frac{1}{12n\epsilon^2}$$

As $n \rightarrow \infty$

$$P\left\{\left|\frac{S_n}{n} - \frac{1}{2}\right| \geq \epsilon\right\} \rightarrow 0$$

$$\frac{S_n}{n} \xrightarrow{P} \frac{1}{2}$$

For any epsilon greater than zero, using Chebyshev's inequality, one can conclude the probability of absolute of S_n by n minus $1/2$ greater than or equal to epsilon that is less than or equal to 1 divided by 12 times n epsilon square. I am using the Chebyshev's inequality by knowing mean of a S_n by n is $1/2$ and variants of S_n by n is 1 divided by $12n$, I get this inequality.

Now as n tends to infinity the probability of absolute of S_n by n minus $1/2$ which is greater than or equal to epsilon will tends to zero because epsilon is in the, n is in the denominator because n is the denominator as n tends to infinity, this probability tends to zero. That is nothing but S_n by n tends to the value $1/2$ and this converges takes place in probability.

The sequence of random variable S_n by n converges to $1/2$ in probability. Therefore, we say the sequence of random variable X_n for n is equal to $1, 2$ and so on obeys the weak law of the large numbers because the S_n by n converges to $1/2$ in probability therefore we say the sequence of random variables X_n 's obeys the weak law of large numbers. So that is the intension of a giving this example.
