Lecture – 34
Chaos in Toral Automorphisms

Welcome to students. So, in the previous class we had looked into toral automorphisms. We had seen some properties of toral automorphisms like what are the basic periodic points, and also that they are topologically transitive. So, as such toral automorphisms tend to be chaotic systems. But today we will be looking into more aspects of chaos of toral automorphisms. Now since this is some kind of a homeomorphism in a 2-dimensional space. So, this is this forms a very nice example of a chaotic system in 2 dimensions.

So, let us now recall toral automorphisms. And we can look into the general definition of toral automorphisms.

(Refer Slide Time: 01:13)

Chaos in Toral Automorphisms

Let $X = \mathbb{R}^n / \mathbb{Z}^n = \mathbb{T}^n$ be any n -torus.
 and $A = (a_{ij})$ be an $n \times n$ matrix with entries in \mathbb{Z}
 and with $\det A \neq 0$.

Define a linear map $L: \mathbb{R}^n \rightarrow \mathbb{R}^n$ as

$$L \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = A \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

$A \in \mathbb{Z}^n$

$T = T_A: \mathbb{T}^n \rightarrow \mathbb{T}^n$ be defined as

$$T(x_1, \dots, x_n)^T = A(x_1, \dots, x_n)^T \pmod{1}$$

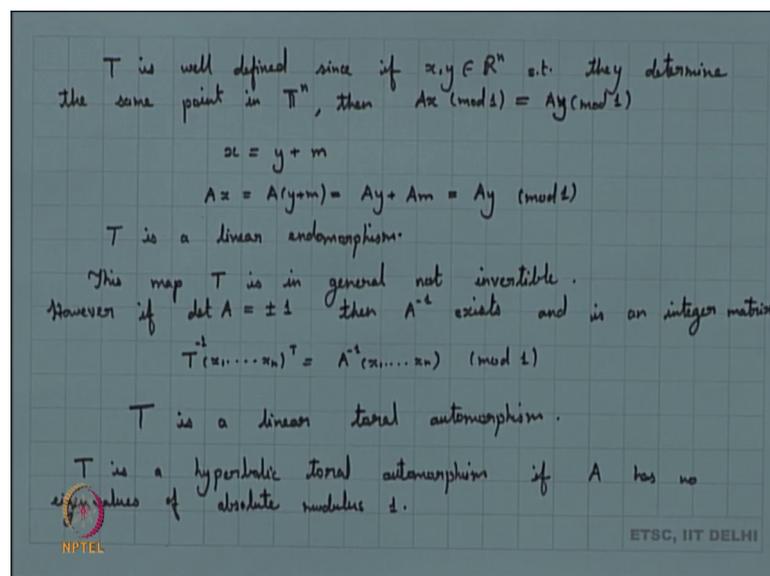

NPTEL ETSC, IIT DELHI

So, let x be say R n upon Z n. So, it is basically T n denoted as T n be any n torus or be an n torus, because there is only one n torus. So, this is an n torus for any n you can think of any n in z a n greater than 1. And let A equal to A ij be an n cross n matrix with integers with entries in z, and with determinant of A not equal to 0. So, this is an invertible matrix that we are looking into with integer entries.

Now, we can define for such an $A \in \mathbb{R}^n$ we know that any matrix will give us a linear transformation on \mathbb{R}^n . So, define a linear map say l from \mathbb{R}^n to \mathbb{R}^n as l of you have this vector $x = (x_1, x_2, \dots, x_n)$ is basically a of $x = (x_1, x_2, \dots, x_n)$. Now you know that very well any linear transformation in a finite dimensional space can be given in terms of a matrix. Now since A is an integer matrix it maps \mathbb{Z}^n onto itself. So, A maps \mathbb{Z}^n to itself, and since A map \mathbb{Z}^n to itself, we can think of A as allowing us to define a linear transformer allowing us to define a transformation on the n torus.

Let T equal to $T(A)$, right from \mathbb{T}^n to \mathbb{T}^n , we defined as T of say l have $x = (x_1, x_2, \dots, x_n)$ transpose is same as a of $x = (x_1, x_2, \dots, x_n)$ transpose mod 1. So, this gives us so, we look into this particular mapping and we first check that this mapping is well defined.

(Refer Slide Time: 04:19)

So, T is indeed well defined. Since if x and y belonging to \mathbb{R}^n such that they determine the same point in \mathbb{T}^n , then $Ax \pmod{1}$ will be same as $Ay \pmod{1}$. The reason here is supposing x and y are 2 points in \mathbb{R}^n which determine the same point in \mathbb{T}^n ; that means, I can write x as say y plus some integer m , and hence they will be basically since these they differ by an integer right.

So, they give you the same point in \mathbb{T}^n . And then you apply A on both the sides, you get Ax equal to $Ay + Am$, which basically happens to be equal to $Ay \pmod{1}$ and if you look into Am this is all having integer coefficients right. So, if I try to take mod 1 right. So, this becomes $Ay \pmod{1}$ right. So, this disappears in that. So, if 2 points

determine in \mathbb{R}^n determine the same thing. So, this basically this mapping T is well defined. So, this mapping T is a linear endomorphism. So, T is now a linear endomorphism, but if we look into general T right, T need not be invertible. The reason is the way we have defined T right, T heavily depends on A and the entries of A are all integers right. That is what is actually helping us in saying that this T is basically mapping points of \mathbb{T}^n into \mathbb{T}^n .

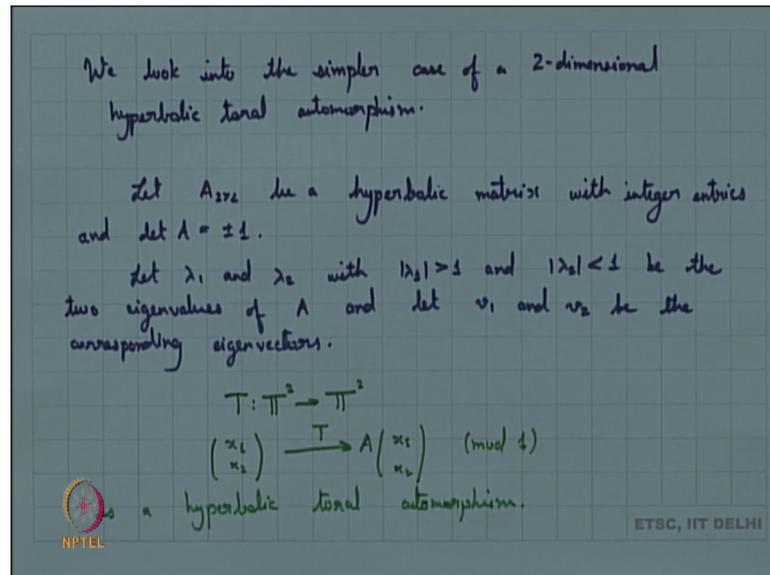

But if we try to look into T inverse, right T inverse need not be i mean T need not be invertible, because T inverse would basically come up from some matrix A right, if you are looking into the linear transformation. It would come up some some matrix A which need not have integer coefficients, but the scenario completely different if we take determinant of A to be plus or minus 1, right. In that case your A inverse will also have integer coefficients or sorry integer entries. So, we see that this T this map T is in general not invertible; however, if your determinant of A is plus or minus 1, then A inverse exists and is an integer matrix.

And what can you say about T inverse? Then my T inverse $x_1 \times x_2 \times \dots \times x_n$ can be written as A inverse. So now, we have an invertible endomorphism right. So, we can say that our T is a linear toral automorphisms. So, T is a linear toral automorphism. And we now want to look into whether this is a hyperbolic toral automorphism or not, and we have seen this earlier. So, we say that T is a hyperbolic toral automorphism, if A has no eigenvalues of absolute modulus value one. So, in that sense we say that T happens to be a hyperbolic toral automorphisms. And as we had seen in the previous lecture, that a hyperbolic toral automorphism is devaney chaotic.

What we will try to see is again we will try to look into the chaos of a hyperbolic toral automorphisms, what we will try to determine is what is the topological entropy for a hyperbolic toral automorphism. In fact, what we are not going to look into is that a hyperbolic toral automorphism can also be conjugated with say if \mathbb{T}^n have an n torus then a hyperbolic toral automorphism can be conjugated with the symbolic system on n symbols, and that gives you like lot of properties because you can think of lot of properties over there because again we know that our symbolic system is some kind of A invertible system, right. And if you are looking into a sub shift of finite type we know that it has various other properties.

So, we can think of conjugating this to in n dimension is in in a symbolic system in n words in an alphabet of set n. But we are not going to get so much into details here. All we will look into what is the topological entropy of a toral automorphism. Now as such for any dimension we can calculate this part, but it becomes easier to demonstrate it in case of 2 dimension. Our eyes are more used to seeing 2 dimension.

(Refer Slide Time: 11:23)

So, what we will do is we will look into the simpler case of a 2-dimensional toral automorphism. So, we start with a simpler case. So, we look into the simpler case hyperbolic toral automorphism. For that we need some let us build up some notations. So, let A cross A sorry a 2 cross 2 B of matrix.

So, let it be a hyperbolic matrix with integer's entries. And determinant of A is plus or minus 1. Let λ_1 and λ_2 with mod of λ_1 greater than 1 and mod of λ_2 less than 1 be the 2 eigenvalues of A . And let v_1 and v_2 be the corresponding eigen vectors. So now, as we have seen what happens here is that you have T from T square to T square defined as say you have x_1 and x_2 and under T they are mapped to A times x_1 and $x_2 \pmod{1}$.

So, this is a hyperbolic, toral automorphism. Now we will try to see a theorem here, and that is what we are going to do in this particular class.

(Refer Slide Time: 14:19)

Theorem:- The topological entropy of the two dimension hyperbolic toral automorphism is given by $h(T) = \log|\lambda_1|$.

Proof:- We will use the Bowen's definition of topological entropy here.

Fix $\epsilon > 0$.

We can cover \mathbb{T}^2 by ϵ -balls centered at a finite set say $\{(x_i, y_i), \dots, (x_k, y_k)\}$.

Around each point (x_i, y_i) $i=1, 2, \dots, k$ describe a disc.

$$B_i = \{(x_i, y_i) + \alpha v_1 + \beta v_2 : -\epsilon \leq \alpha, \beta \leq \epsilon\}$$

where v_1 and v_2 are eigenvectors corresponding to the eigen values λ_1 ($|\lambda_1| > 1$) and λ_2 ($|\lambda_2| < 1$). $|v_1| = \frac{1}{|\lambda_1|} = |v_2|$.

These discs B_i can be taken to cover \mathbb{T}^2 .

So, we look into the theorem, the topological entropy of the 2-dimensional hyperbolic toral automorphism is given by log of lambda 1 or I should say log of modulus of lambda 1. So, the topological entropy of a toral automorphism is log of mod lambda 1. And since lambda 1 happens to be the larger eigenvalue of a toral automorphism. We know that the topological entropy is positive and hence the hyperbolic toral automorphism is chaotic.

So, let us now look into the proof of this part. Now we know that we can start with our topological entropy we can start the definition with either of the 2 definitions we can either use the Adler's definition, since this is a torus is a compact metric space, we can either use the Adler's definition or we can use a Bowen's definition. But here it will be easy for us to use the Bowen's definition. So, we will use the Bowen's definition of topological entropy.

So now for Bowen's definition, all we need to find out is some n epsilon separated sets. So, let us start working it out. So, we first fix an epsilon. Now we can cover T square by epsilon balls centered at a finite set, say my finite set is $x_1 y_1 \dots x_k y_k$. Now when we are looking into epsilon balls this is our T square is gone factor i. So, it will have a finite epsilon net, but when I am looking into covering it by epsilon balls. I am defining my balls not using any matrix. So, as a different kind of metric that we are trying to use over here or I would say that the definition of balls here is slightly different from what you could see as an ordinary say ball of radius epsilon centered at this points.

We are taking a slightly variation we are taking some variation in the definition. So, how do we define a ball here is; see, around each point $x_1 y_1$, say around each point $x_i y_i$ for each of this I we define a box. So, my box is B_i which is basically $x_i y_i$ plus alpha times v_1 plus beta times v_2 , such that $-\epsilon < \alpha \leq \beta < \epsilon$. So, this is a kind of box that we are using. So, one can think of this in terms of say, we now have at each point we have 2 directions, right. We have this linearly independent directions v_1 and v_2 , and along is each of these directions what we are trying to do is we are trying to take minus epsilon; epsilon around one direction minus epsilon; epsilon on another direction, that gives us a kind of a box.

And we can think of very well we can think of this to be defining our open spheres, right. And as we know that our space is compact, there are finitely many of them which cover the whole torus. So, here my v_1 and v_2 are eigenvectors corresponding to the eigenvalues. Now we keep in mind that when I am talking of $\lambda_1 \bmod \lambda_1$ is greater than 1 and λ_2 . So, here in my $\lambda_2 \bmod \lambda_2$ is less than 1. We know that these boxes right. So, we can think of this as an epsilon net $x_1 x_1 y_1 y_1$. And so, these boxes B_i can be taken to cover T square, right.

So, how many number of boxes you have? You have number of boxes your boxes are covering here T square they are covering your torus. So, let us try to see how a typical box is.

(Refer Slide Time: 20:55)

The slide contains a diagram and mathematical text. On the left, a point $c_i = (x_i, y_i)$ is shown inside a tilted box B_i . On the right, a rectangular box B_i is shown with a point (x_i, y_i) inside, and axes labeled v_1 and v_2 . Below the diagrams, the text reads:

Consider the set of points C_i

$$C_i = \left\{ (x_i, y_i) + \frac{j\epsilon}{|\lambda_1|^k} v_2 : j = -\lfloor |\lambda_1|^k \rfloor, \dots, \lfloor |\lambda_1|^k \rfloor \right\}$$

$$\subset B_i$$

$$|C_i| = 2 \lfloor |\lambda_1|^k \rfloor + 1.$$

At the bottom left is the NPTEL logo, and at the bottom right is the text "ETSC, IIT DELHI".

So, say we are looking into so, for example, this is our unit square. And in this unit square we are typically having supposing, this is my point $x_i y_i$, then I have 2 directions and in both these directions. I am looking into minus epsilon epsilon. So, this is basically giving my box B_i . So, this is my box B_i and then along any every such point, right. I would be having some such boxes right covering the whole of torus, right. We can think of such boxes covering the whole of torus.

So, these boxes they cover the whole of torus. And we have a typical box B_i where you have one direction. So, you have this longer direction basically in the direction of v_1 , right. The shorter direction is basically in the direction of v_2 . So, typically I can write my B_i . So, supposing this is the box B_i . So, this is basically the box B_i , and we have this point $x_1 y_1$ lying over here $x_i y_i$ lying over here. So, you have $x_i y_i$ lying over here, and we know that this is basically the direction of v_1 . And this is basically going in the direction of v_2 , right. And we may not have seen this, but what we will try to do here is, when we take our very eigenvectors v_1 and v_2 .

Let us also assume that the magnitude of v_1 is 1. And so, is the magnitude of v_2 . So, basically let us take our eigenvectors to be unit vectors right. So, we can start with our eigenvectors to be unit vectors. So, that we do not have to worry about whatever length it is right this. So, these are unit vectors; however, for us what is important is the direction. So, we start with them our eigenvectors to be unit vectors, we have this boxes B_i and now let us consider the set of points C_i . So, consider the set of points C_i , where i am defining my C_i to be the set of all points of the form $x_i y_i$ plus j times epsilon upon mod of λ_1 to the power k in the direction of v_1 , such that your j lies so, j takes all the values between you have minus now you are looking into. So, you have mod of λ_1 to the power k . You are looking into the integer value of mod of λ_1 to the power k . So, from minus integral part of mod of λ_1 to the power k to the integral part of mod of λ_1 to the power k , you have these many points. So, these are basically $2k + 1$ points, right. So, you are looking into these points here. Now sorry, not $2k + 1$ this would be exactly 2 times mod of integral part of λ_1 to the power k plus 1 .

So, you are looking into these points we are considering these points C_i . Now what are this points C_i over here if I want to see that. So, basically in the direction of v_1 right we have this points here right. So, these are the points in the direction of v_1 . So, basically, we are looking into these points. So, our C_i basically typically is a subset of B_i it is in the

box. So, all these points C_i are from the box B_i and what is the cardinality of C_i . So, looking to the cardinality of C_i . The cardinality of C_i turns out to be twice the integer value of $\text{mod } \lambda^{-1}$ to the power k , right plus 1.

So, is basically the cardinality of each C_i . Now we want to claim something.

(Refer Slide Time: 26:02)

Claim: $C = \bigcup_{i=1}^k C_i$ is a $(k, 2\epsilon)$ separated set for (\mathbb{T}^n, T)

Note that for any point $(z, w) \in \mathbb{T}^n$ we can choose some $i = 1, \dots, k$ s.t. $(z, w) \in B_i$ and so

$$(z, w) = (x_i, y_i) + \alpha v_1 + \beta v_2 \text{ for some } -\epsilon \leq \alpha, \beta \leq \epsilon.$$

If we choose j s.t. $-\lfloor \lambda_1^k \rfloor \leq j \leq \lfloor \lambda_1^k \rfloor$

$$\text{s.t. } \left| \alpha - \frac{j\epsilon}{\lambda_1^k} \right| \leq \frac{\epsilon}{2\lambda_1^k}.$$

then let $(z_j, w_j) = (x_i, y_i) + \frac{j\epsilon}{\lambda_1^k} v_1 \in C_i$.

Now for $0 \leq n \leq k$, we have

$$T^n(z, w) = T^n(z_j, w_j) + \left(\alpha - \frac{j\epsilon}{\lambda_1^k} \right) \lambda_1^n v_1 + \beta \lambda_1^n v_2$$

NPTL ETSC, IIT DELHI

So, what we claim here is take C to be the union of all such C_i . So, looking into C_i with i going from one to k . So, C is a k twice epsilon separated set for T square T . So, want to be claimed and this happens to be a k twice epsilon separated set to see to we first prove this claim. So, we note that for any point z, w and T square we can choose some, i say we know that we have this k boxes right. So, basically our z, w will be lying in one of these boxes right.

So, we can choose some i such that your z, w lies in this box B_i because B_i is cover the torus. And so, since the property of v_1 is it contains all those points which are at a distance α times v_1 plus β times v_2 from x_i, y_i . So, we can say that your z, w is x_i, y_i plus α times v_1 plus β times v_2 for some α, β which lies between minus epsilon and epsilon. So now, we are fixing our α and β also, depending on this point z, w . If we choose our j such that we are choosing your j between minus λ^{-1} to the power k integer value of $\text{mod } \lambda^{-1}$ to the power k less than or equal to j less than or equal to integer value of λ^{-1} to the power k .

If you are choosing your j between this part right, or I should say in in this range right, such that your mod of because you have already fixed an alpha here. So, your mod of alpha minus j times epsilon upon mod of lambda 1 to the power k , if I am looking into this modulus. So, this modulus is less than or equal to epsilon by 2 mod of lambda 1 to the power k . Supposing, I want to choose this j such that this inequality is satisfied. Now if you look back into our figure, this you can always find such a j , right. Because your z w lies somewhere over here right.

So, you have these points j . So, these are basically a points j right. And since they will be lying somewhere over here, I can choose that particular value of j for which this inequality is satisfied. So, this is possible. And then we will let now I am taking my point z j w to be equal to this x_i y_i plus j times epsilon upon mod lambda 1 to the power k times v 1. So, if I chose this part, then this point with this particular coefficient this j here, right. This will be basically a point of C_i . What remains to see is that this happens to be a separated set. So, take any z w in B_i , right you have some j right for a any z w in B_i you have A_j for which this inequality satisfied. And in that case, you can always choose a point z_j w_j right in C_i which is basically having, which has basically this equation right. So, it is basically your point $z_j w_j$ can be fixed, right for a given j , once you know what is your z w .

So now given a z w basically given as z w we are choosing a z_j w_j in C_i , or in C . Now since your z w could be in any B_i , right for any z w in the torus, you have a point here fixing a point of C . Now for what happens is 0 less than or equal to r less than or equal to k , what happens here is we have Tr of z w is basically Tr of z_j w_j , right plus I have alpha minus j times epsilon upon mod lambda 1 to the power k times a to the power r v 1 plus beta times a to the power r v 2. So, this is basically my Tr z w . And hence if I am looking into this equation. So, I want to say that this is basically this equation.

(Refer Slide Time: 32:48)

and so

$$|T^n(z, w) - T^n(z_j, w_j)| \leq \left| \alpha - \frac{j\epsilon}{|\lambda_1|^k} \right| |\lambda_1|^n + |\beta| |\lambda_2|^n$$

$$\leq \frac{\epsilon}{2|\lambda_1|^k} \cdot |\lambda_1|^n + |\beta| |\lambda_2|^n$$

$$< \frac{\epsilon}{2} + \epsilon < 2\epsilon$$

Hence C is a $(k, 2\epsilon)$ separated set.

The cardinality of the $(k, 2\epsilon)$ separated set C is at most $k(2(\lceil |\lambda_1|^k \rceil) + 1)$ which gives an upper bound of $n(k, 2\epsilon, T)$ of the $(k, 2\epsilon)$ separated set in \mathbb{T}^k .

Hence,
$$h(T) = \lim_{\epsilon \rightarrow 0} \lim_{k \rightarrow \infty} \frac{1}{k} \log(n(k, 2\epsilon, T))$$

$$\leq \lim_{\epsilon \rightarrow 0} \lim_{k \rightarrow \infty} \frac{1}{k} \log(k(2(\lceil |\lambda_1|^k \rceil) + 1))$$

$$= \log |\lambda_1|.$$

NPTEL ETSC, IIT DELHI

And according to this equation what is my mod of $T^r z w$ minus $T^r z_j w_j$? This modulus would be less than or equal to now we again come back to this equation right.

So, I am taking this on the other side what is this modulus. So, this modulus will be less than or equal to modulus of this part. But now if I look into my v_1 and v_2 , these are both are linearly independent right. So, the modulus of this vector will be basically less than or equal to I can take the modulus of this and take the modulus of that. Again, your v_1 happens to be a eigenvector for A^r right. So, $A^r v_1$ would be same as λ_1 to the power $r v_1$. And $A^r v_2$ would be same as λ_2 to the power $r v_2$.

So, what happens here is what is this modulus, this modulus is less than or equal to we have this modulus of α minus j times ϵ upon mod λ_1 to the power k times λ_1 mod λ_1 to the power r , plus mod β into mod of λ_2 to the power r we have already taken over v_1 and v_2 to be unit vectors. So, the modulus of them will be 1. So, what is this less than equal to I can say that this would be less than or equal to we have already taken what is this part, right we have already assumed that we are choosing our j . So, that this particular modulus is less than ϵ by 2 mod λ_1 to the power k .

So, what we have here is this is less than or equal to say ϵ by 2 mod λ_1 to the power k , into mod λ_1 to the power r plus you have mod of β right to the

power $\lambda \bmod \lambda^2$ to the power r into $\bmod \lambda^2$ to the power r . Now think of this factor, your λ to the power r upon λ to the power k , right this quantity is less than 1. This is basically $\bmod \lambda$ to the power or I should say 1 upon $\bmod \lambda$ to the power k minus 1. This quantity is less than 1. So, I can say that this would be less than ϵ by 2, what happens to this quantity? We know what is our bit where is our β lying it is lying between minus ϵ to ϵ .

So, $\bmod \beta$ at the most you can have value ϵ . And if I look into $\bmod \lambda^2$ to the power n right $\bmod \lambda^2$ is less than 1. So, $\bmod \lambda^2$ to the power r is also going to be less than 1 right. So, this is less than ϵ right and in all we can say that this would be less than twice ϵ . So, what we have here is that our C happens to be hence C is a k twice ϵ separated set. And now what is the cardinality of C ? So, if you look into the cardinality of C . So, the cardinality of is at most twice right we have seen what is the cardinality of C_i .

So, the cardinality of C_i happens to be at most integer value of λ to the power k plus 1, right. This was the cardinality of C_i . But sorry, but if I look into what is the cardinality of C there will be k such C_i right. So, the cardinality of C happens to be this factor, which gives an upper bound of we know that we want to look into the maximum cardinality of an k twice ϵ separated set. So, this gives an upper bound for that maximum cardinality. So, $k \epsilon T$, right of the k twice ϵ separated set in T square right.

So, in the torus, and hence what we have is the topological entropy happens to be equal to limit as ϵ tends to 0, right limit as k tends to infinity, right I have 1 upon $k \log$ of $r k$, sorry this is twice ϵ ϵT . And this turns out to be less than or equal to limit as ϵ tends to 0 limit as k tends to infinity you have 1 upon k times \log of, because this quantity is having this as an upper bound right. So, I have \log of k times 2 twice integer value of λ to the power k plus 1. And if I want to look into that factor right if I try to take this limit as ϵ tends to 0, and this limit as k tends to infinity, this turns out to be equal to \log of $\bmod \lambda$.

(Refer Slide Time: 39:28)

$h(T) \leq \log |\lambda_1|$

Fix $(x, y) \in \mathbb{T}^2$ and for $\epsilon > 0$ and $k \geq 1$ consider
 $D = \left\{ (x, y) + \frac{j2\epsilon}{|\lambda_1|^k} v_1 : j = -\lfloor |\lambda_1|^k \rfloor, \dots, \lfloor |\lambda_1|^k \rfloor \right\}$

Claim: - D is a $(k, \frac{2\epsilon}{|\lambda_1|^k})$ separated set.
 Take two distinct points (a_1, b_1) and $(a_2, b_2) \in D$
 and let $0 \leq r \leq k-1$.

$$|T^r(a_1, b_1) - T^r(a_2, b_2)| = \left| \frac{(j-i)2\epsilon}{|\lambda_1|^k} T^r(v_1) \right|$$

$$\leq \frac{2|j-i|\epsilon}{|\lambda_1|^{k-r}}$$

$s(k, \epsilon, T) = |D| = 2\lfloor |\lambda_1|^k \rfloor + 1$ is a lower bound of a
 (k, ϵ) separated set in \mathbb{T}^2 and hence,

ETSC, IIT DELHI

And so, the result that we have here is that your entropy of T is less than or equal to \log mod lambda 1. Now this is one way right, as we have seen this is just in a single direction. We will try to look into this inequality the other way round also. What we had done is that we had found out the upper bound for $n \geq 2$ epsilon for a $k \geq 2$ epsilon separated set, we can find similarly we can find a lower bound also. So, that would give us the reverse inequality. So, we fix an xy in T square, and for epsilon greater than 0 and k greater than equal to 1, we consider D to be equal to the set of all xy plus say j times 2 epsilon upon mod of lambda 1 to the power k times v_1 , right. Such that your j varies from minus integer part of mod lambda 1 to the power k to the integer part of mod lambda 1 to the power k .

Let us look into this set d . Now our claim here is D is a $k \geq 2$ epsilon upon mod lambda 1 to the power k separated set. So, take any 2 distinct points a_1 and b_1 . So, take 2 distinct points say $a_1 b_1$ and $a_2 b_2$ and let $0 \leq r \leq k-1$. So, what we have here is mod of T to the power r $a_1 b_1$ minus T to the power r $a_2 b_2$ this is basically a mod of I am looking into this factor it is basically mod of j . So, I have this $a_1 b_1$ and I can write my $a_1 b_1$ as this factor right some j here.

So, this is basically j times 2 epsilon upon lambda 1 to the power k $a_1 b_1$. And I can take my $a_2 b_2$ to be basically this plus i times 2 epsilon upon lambda 1 to the power k . So, this would be some j minus i times 2 epsilon right upon mod lambda 1 to the power

k, right into T to the power r of v 1. And this we can very well see that this would basically be should say it would be less than or equal to or basically this will exactly be equal to this is twice, now I had twice mod j minus i epsilon, right I have lambda 1 to the power k here.

So, and I have this is again lambda 1 to the power r here. So, this would be upon mod lambda 1 to the power upon k minus r. So, I am see thinking of this part. So, this would exactly be equal to this factor. So, if I take my set s. So, if I look into my s k epsilon T, this happens to be the cardinality of D. And the cardinality of D is twice, right again I have integer value of lambda 1 to the power k plus 1, right is a lower bound of a k epsilon separated set. I can think of because this was just a constant k epsilon separated set in T square.

And hence what do we have here now?

(Refer Slide Time: 44:19)

The image shows a handwritten derivation on a grid background. The equations are as follows:

$$h(T) = \lim_{\epsilon \rightarrow 0} \lim_{k \rightarrow \infty} \frac{1}{k} \log (s(k, \epsilon, T))$$

$$\geq \lim_{\epsilon \rightarrow 0} \lim_{k \rightarrow \infty} \frac{1}{k} \log (2[\lambda_\epsilon]^k + 1)$$

$$= \log |\lambda_\epsilon|$$

The result $h(T) \geq \log |\lambda_\epsilon|$ is enclosed in a hand-drawn box. Below it, another box contains the equation $h(T) = \log |\lambda_\epsilon|$.

Logos for NPTEL and ETSC, IIT DELHI are visible at the bottom of the slide.

So, the entropy of T is basically limit as epsilon tends to 0 limit as k tends to infinity 1 upon k log of s k epsilon T can think of that part. And that becomes greater than equal to because I just know a lower bound for this term. So, this becomes greater than equal to limit as epsilon tends to 0, limit as k tends to infinity, I have 1 upon k times log of twice integer value of lambda 1 to the power k, right plus 1. And this is basically our log mod lambda 1.

And hence from this equation we get that the topological entropy of T is greater than or equal to $\log \text{mod } \lambda_1$. You look into this fact the first time we proved that topological entropy of T is less than or equal to $\log \text{mod } \lambda_1$. Now we have a result saying that topological entropy of T should be greater than equal to $\log \text{mod } \lambda_1$. And that proves that topological entropy of T is basically equal to $\log \text{mod } \lambda_1$. Where λ_1 happens to be the eigenvalue with modulus greater than 1 for the hyperbolic matrix A . And I hope this is clear to all of you. So, your hyperbolic toral automorphism is a chaotic system. We look into more chaos in the next class.
