Module - 05
Higher Dimensional Distributions
Lecture - 24

We are moving into the 5th module; let me recall first module we discussed the basics of probability. And the second module we discussed the random variable and the third module we discussed the movements and inequalities and the fourth module we discussed the standard distributions both the discrete and continuous type.

(Refer Slide Time: 00:53)

Now, we move in to the 5th module that is random vectors in most of the random experiment you may have a ω in which you may be able to create many random variables simultaneously. And also sometimes the interest will be finding the some measures together or given one set of measures takes this value what could be the distribution of other random variable? Or sometimes you may interest to find the distribution of more than one random variable at the same time. So, till now we have discussed only one random variable and then later we have discussed a function of a random variable; that means, again that is another one random variable. There is a

possibility you may need to study more than one random variables at the same time or simultaneously or together, in that case you need a random vector.

When we use the word random vector; that means, it is n dimensional random variable; that means, we put a n random variables together that we call it as a n dimensional random variables or random vectors of size n . That means, each one is random variable and we are studying n random variables together or jointly. Many real world problem you may need to study the distributions of a more than one random variable jointly therefore, we need a random vector. That means, whatever we have understood the concept of a random variable and their distributions and movements; the same concept has to be extended from one dimensional to multi dimensional.

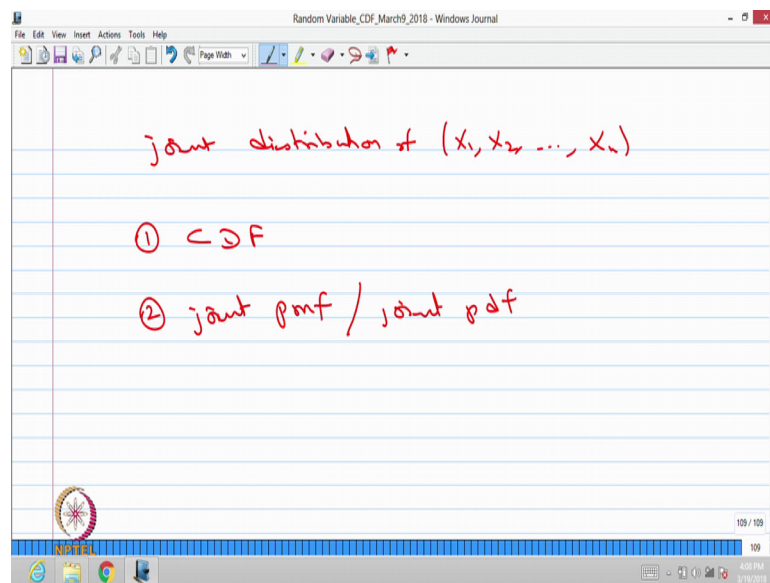

So, whatever the calculus we have used calculus means finding the integration or finding the derivative and so on; whatever we have done the calculus part with the one dimensional variable or one variable, now we have n dimensional random variable. So, the corresponding calculus of several variables has to be used. Let me explain it how the random vector coming into the picture. The ω consist of many samples, it could be finite or countable infinite or uncountable many. The random variable one random variable is defined as a X_1 .

Another random variable defined from the ω that is X_2 like that there are many more random variables defined in the ω that is a real valid function from ω to \mathbb{R} satisfying the condition that is X inverse of minus infinity to small x semi closed interval belonging to F then only the real value function is a random variable. That means, you have a probability space ω, F, P , ω is a collection of all possible outcomes and F is the sigma filled on ω and P is the set function satisfying the 3 conditions the Kolmogorov accemetrix condition. Therefore, P is the probability; so, this is the probability space.

In this probability space X_1 is defined the same probability space X_2 is defined like that many more random variables are defined in the same ω . Now we are going to create a random vector by making a few random variables together or jointly; that means, if you go for X_1 comma X_2 together then this is called 2 dimensional random variables or it is a random vector of size 2×1 and X_2 ; that means, the same ω, X_1 comma X_2 is defined such that the possible values is going to be in the 2 dimensional plane.

This is X_1 and this is X_2 ; earlier the X_1 is defined from ω to r now the X_1 comma X_2 is defined from ω to $r \times r$. So, again each one X_1 is random variable X_2 is a random variable together we call it as a random vector of size 2 or 2 dimensional random variable. The same way one can define n dimensional random variable $X_1 X_2$ and so on till X_n ; each one is a random variable therefore, this is a n dimensional random variable in short r vs random variables.

(Refer Slide Time: 06:45)

That means, we can go for finding what is the joint distribution of n dimensional random variable X_1 comma X_2 so on X_n .

Earlier we used a word distribution of X_1 , now we are studying the distribution of n random variable together or jointly. Therefore, it is called a joint distribution of n dimensional random variables. So first we can discuss; what is the CDF Cumulative Distribution Function; if it is a discrete type random variable one can discuss; what is a joint probability mass function; if each random variables of the continuous type then one can study what is a joint probability density function of n dimensional random variable.

Initially, we study all the random variables of that discrete type or all the random variables are of the continuous type. Later we will see one random variable of the discrete type and the other one is of the continuous type and so on that we will do it in the later.

So, our interest is to find the joint distribution of n dimensional random variables in which each one is a random variable; that means, that satisfies the definition of random variable. Therefore, this is a n dimensional random variable first let us go for how to give the definition of joint CDF joint.

(Refer Slide Time: 08:31)

The image shows a handwritten derivation of the joint CDF of two random variables X_1 and X_2 . The text is written in red ink on a blue-lined background. The derivation starts with the title "Joint CDF of (X_1, X_2) ". Below this, the joint CDF is defined as $F(x_1, x_2) = P\{X_1 \leq x_1, X_2 \leq x_2\}$. To the right of this equation, the ranges for x_1 and x_2 are specified as $-\infty < x_1 < \infty$ and $-\infty < x_2 < \infty$. The next step shows the joint CDF as a probability of an event: $= P\left\{ \omega \mid \begin{array}{l} X_1(\omega) \leq x_1, \\ X_2(\omega) \leq x_2, \omega \in \mathcal{R} \end{array} \right\}$. A red bracket underlines the event description, and it is labeled as " A_{x_1, x_2} - event".

CDF of instead of going for the n dimensional random variable first we will restrict to the 2 dimensional random variables. Once we discuss the 2 dimensional random variables CDF, then it is easy to visualize or easy to understand for more than 2 dimensional random variable ok. It is X_1 comma X_2 the joint CDF can be written as the 2 functions x_1 comma x_2 is nothing but the probability of capital X_1 is less than or equal to small x_1 , capital X_2 is less than or equal to small x_2 .

Both x_1 and x_2 lies between minus infinity to infinity. Similar way we have defined the CDF of 1 dimensional random variable, now we are defining the CDF of 2 dimensional random variable with the 2 variables small x_1 comma small x_2 that is nothing but probability of capital X_1 is less than or equal to small x_1 and capital X_2 is less than or equal to small x_2 .

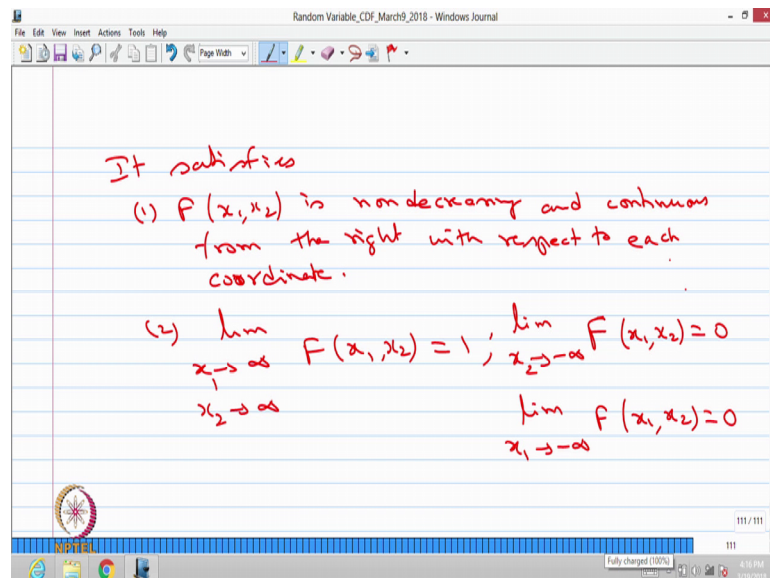

That is nothing but P of collection of ω such that under the operation X_1 the ω has to be less than or equal to x_1 ; that means, this value can lie between minus infinity to small x_1 . Also the same ω under the operation X_2 , it gives the value small x_2 . And the ω 's belonging to Ω ; that means, we are collecting a few possible outcomes satisfying

the condition under the operation X_1 it should give the value less than or equal to x_1 under the operation of X_2 it gives a values less than or equal to small x_2 .

So, we are collecting those possible outcomes then finding the probability and that probability of these possible outcomes satisfying this condition that is going to be the CDF at the point X_1 comma X_2 where small x_1 can lie between minus infinity to infinity small x_2 also lies between minus infinity to plus infinity. The collection of w such that this condition we can label this as the A suffix x_1 comma x_2 this is a event because whenever you collect a few possible outcomes; that is nothing but the event.

So, the event A suffix x_1 comma x_2 that is a event; that means, the probability of event by using a Kolmogorov accemetric definition probability of any event or P of any event always greater or equal to 0 and P of ω is equal to 1 and P of union of A_i 's that is equal to summation of P of A_i 's as long as A_i 's are mutually disjoint events. With the same logic the P of any event getting from the different values of small x_1 and x_2 ; this is also going to satisfy the Kolmogorov accemetric definition. Therefore, one can make what are all the conditions or what are all the properties is going to be satisfied by this capital F .

(Refer Slide Time: 12:43)

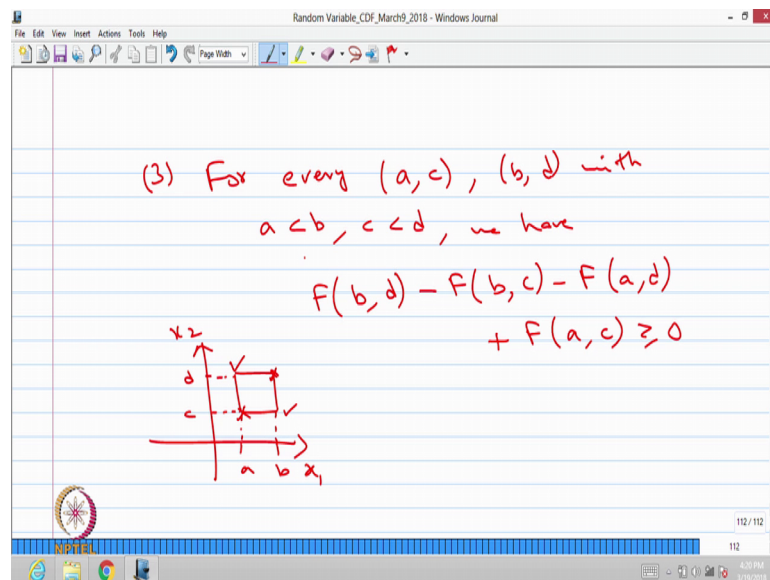

So, let me write down; it satisfies, it satisfies the first condition the capital F of x_1 comma x_2 that is non decreasing and continuous from the right.

That means it is a right continuous with respect to with respect to each coordinate, each coordinate that is $x_1 \times x_2$ it is a non-decreasing as well as a continuous from right with respect to each coordinate that is a first point. Second point the limit of x_1 tends to plus infinity x_2 tends to plus infinity; the CDF x_1 comma x_2 limit x_1 tends to plus infinity x_2 tends to plus infinity, F of x_1 comma x_2 is always 1.

And the limit x_2 tends to minus infinity of F of x_1 comma x_2 that is equal to 0 and the limit x_1 tends to minus infinity F of x_1 comma x_2 that is also 0. When both becomes a positive infinity, it becomes 1 when either one of them is minus infinity and the limit extends x_2 tends to minus infinity or limit x_1 tends to minus infinity that function of x_1 comma x_2 that is going to be 0.

(Refer Slide Time: 15:11)

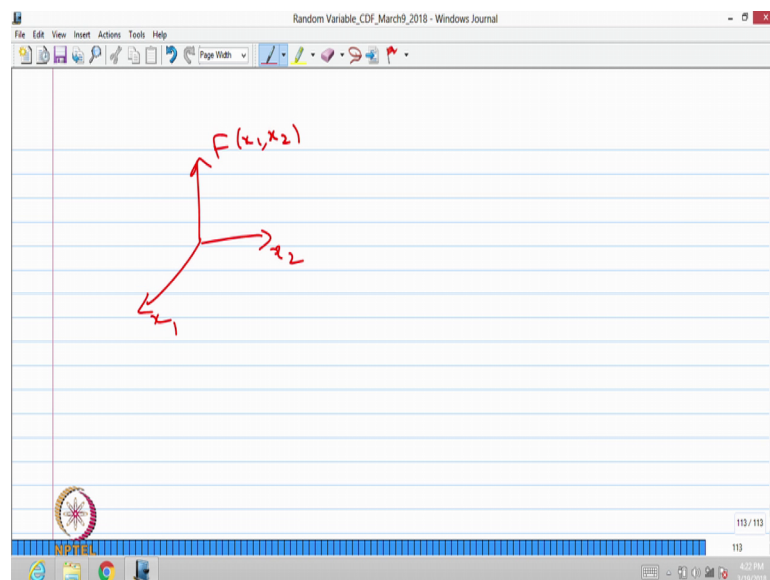

The third point for every a comma c and b comma d with a is lesser than b and c is lesser than d ; we have I can just draw the diagram first then I can go for it that is easy. So, I can take as small box in which this is going to be a and this is going to be b and this is going to be c and this is going to be d correct. I can go for after drawing the diagram. Now I can go for F of b comma d minus F of b comma c minus F of a comma d plus F of a comma c which is greater or equal to 0.

So, the cross is going to have a positive symbol and a tick mark has a negative symbol; that means, F evaluated at b comma d minus F evaluated at a comma d and b comma c with the minus sign then plus F evaluated at a comma c that value has to be greater or

equal to 0. Whenever you have a 2 dimensional random variable whose CDF always satisfies a these 3 conditions. The third condition is a very important condition in the sense even you may have a real valued function with a 2 variables satisfying these 2 conditions may not be a CDF of 2 dimensional random variable unless otherwise it satisfies a third condition.

But if you have a 2 dimensional random variable, you will have a always unique CDF with the 2 variables that satisfies all these 3 conditions. CDF of 2 dimensional random variables can be represented in the form of graphical.

(Refer Slide Time: 18:01)

So, one can visualize the CDF in the form of x axis x_1 , x_2 and this is going to be F of x_1 comma x_2 . So, this is possible only for 2 dimensional x_1 is one random variable, x_2 is another random variable. So, z axis that is a CDF of x_1 comma x_2 whereas, you cannot visualize you cannot make a graphic representation of more than 2 dimensional random variable.

(Refer Slide Time: 18:44)

Example Let (X_1, X_2) be a 2 dim r.v.
 with

$$F(x_1, x_2) = \begin{cases} 0, & x_1 < 0 \text{ or } x_1 + x_2 < 1 \text{ or } x_2 < 0 \\ 1, & \text{otherwise.} \end{cases}$$

$$P\left(\frac{1}{3} \leq X_1 \leq 1, \frac{1}{3} \leq X_2 \leq 1\right) = F(1, 1) - F(1, \frac{1}{3}) - F(\frac{1}{3}, 1) + F(\frac{1}{3}, \frac{1}{3})$$

$$= 1 - 1 - 1 - 0 = -1 \neq 0$$

$$\therefore F(x_1, x_2) \text{ is not a CDF of the } (X_1, X_2).$$

Let us go for one simple example in which we can conclude whether this is going to be CDF or not. As example let X_1, X_2 be a 2 dimensional random variables with CDF $F(x_1, x_2)$ that is either 0 when x_1 is less than 0 or $x_1 + x_2$ is lesser than 1 or x_2 is lesser than 0. It takes a value 1 otherwise verify whether the capital F is going to be the CDF of 2 dimensional random variable; that means, this is real valued function with a 2 variables.

Whether this satisfies the 3 properties which we have given; if all these 3 properties are satisfied then you can conclude this will be the CDF of 2 dimensional random variable. You can easily verify the first 2 properties the function is a non decreasing as well as continuous from the right. Similarly, you can easily verify the limit of x_1 tends to plus infinity, x_2 tends to plus infinity that value is 1. Either x_1 is minus infinity or x_2 is minus infinity the limit is going to be 0 that also can be easily verified.

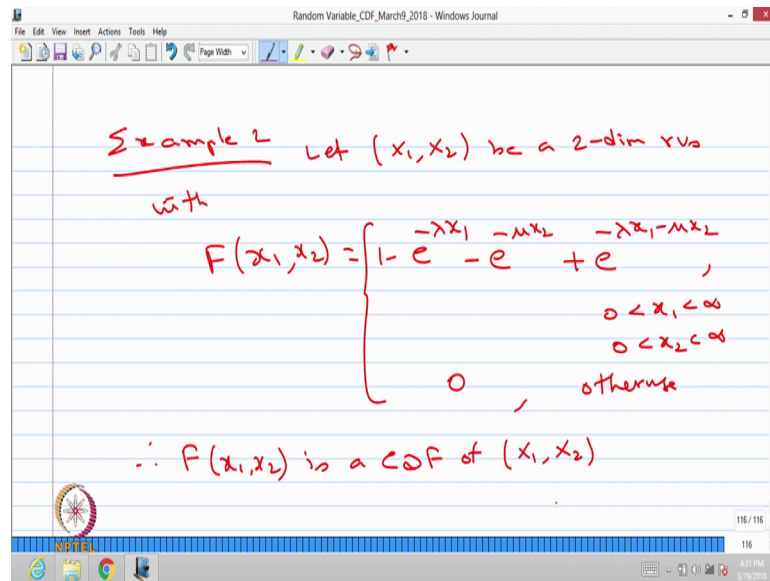

We have to verify the third condition that is the for any 2 points; the CDF of the difference had a 2 points with a positive sign, 2 points with the negative sign has to be greater or equal to 0. For example, you do it with the probability of X_1 lies between X_1 lies between one third to 1 comma X_2 is lies between one third to 1.

If you compute this probability that is nothing but F at the point 1 comma 1 minus F at the point 1 comma one third; I am using the same property minus F one third comma 1 plus F one third comma one third. If you substitute the value F of 1 comma 1 that is 1, F

of 1 comma one third that is again 1, F of one third comma 1 again 1, F of one third comma one third that is 0. And this value is going to be minus 1 which is not greater or equal to 0. So, for any arbitrary points this third property has to be satisfied.

So, since the third property is not satisfied; you can conclude a this F is not a CDF of the random vector X_1 comma X_2 or the 2 dimensional random variables X_1 comma X_2 .

(Refer Slide Time: 22:58)

We will give some example in which that is going to be CDF. So, example 2 let X_1 comma X_2 be a 2 dimensional random variables with the function F of x_1 comma x_2 is $1 - e^{-\lambda x_1} - e^{-\mu x_2} + e^{-\lambda x_1 - \mu x_2}$ for $0 < x_1 < \infty$ and $0 < x_2 < \infty$, otherwise 0.

So, this is going to be the value when both x_1 and x_2 lies between 0 to infinity; otherwise it is 0. We can verify whether this is going to be the CDF of 2 dimensional random variables. By seeing the function you can easily say when x_1 and x_2 is the positive infinity, it becomes 1; either x_1 or x_2 is going to be minus infinity that is going to be 0. And it is a non decreasing function and continuous from the right therefore, the properties 1 and 2 are easily satisfied.

For different values one can able to verify the third property also will be satisfied therefore, hope one can conclude this is going to be the CDF of 2 dimensional random

variables. So, I am not giving the proof of the third property. But that can be verified we can conclude this is going to be the CDF of 2 dimensional random variables.

(Refer Slide Time: 25:08)

The image shows a handwritten derivation in a software window titled "Random Variable_CDF_March9_2018 - Windows Journal". The text is written in red ink on a blue-lined background. The derivation is as follows:

$$\begin{aligned}
 &\text{Suppose, we know the CDF of } (X_1, X_2). \\
 F_{X_1}(x_1) &= P(X_1 \leq x_1) \\
 &= P\left((X_1 \leq x_1) \cap \bigcup_{x_2} (X_2 \leq x_2)\right) \\
 &= P\left(\bigcup_{x_2} (X_1 \leq x_1, X_2 \leq x_2)\right) \\
 &= \lim_{x_2 \rightarrow \infty} P(X_1 \leq x_1, X_2 \leq x_2) \\
 &= \lim_{x_2 \rightarrow \infty} F(x_1, x_2)
 \end{aligned}$$

Suppose we know the CDF of X_1, X_2 ; one can able to find the CDF of any one random variable, that is one can find the CDF of random variable X_1 as a function of small x_1 that is nothing but probability of X_1 less than or equal to small x_1 . That is same as probability of X_1 less than or equal to small x_1 which intersect all the union of X_2 less than or equal to small x_2 ; for all possible values of x_2 . That is same as the probability of union of all possible values of small x_2 , X_1 is less than or equal to x_1 and X_2 is less than or equal to small x_2 .

That is same as the P of union is nothing but limit X_2 tends to infinity P of X_1 less than or equal to small x_1 capital X_2 less than or equal to small x_2 . That is same as limit X_2 tends to infinity capital F of x_1 with x_2 . That means, if you know the CDF of x_1 comma x_2 by taking limit of the other variable tends to plus infinity that will give the CDF of the other random variable.

(Refer Slide Time: 27:41)

Handwritten notes on a digital notepad:

$$F_{X_2}(x_2) = \lim_{x_1 \rightarrow \infty} F(x_1, x_2)$$

$$X = (X_1, X_2, \dots, X_n)$$

with CDF F

$$F_{X_j}(x_j) = \lim_{x_1 \rightarrow \infty} \lim_{x_2 \rightarrow \infty} \dots \lim_{x_{j-1} \rightarrow \infty} \lim_{x_{j+1} \rightarrow \infty} \dots \lim_{x_n \rightarrow \infty} F(x_1, x_2, \dots, x_n)$$

$j = 1, 2, \dots, n$

Similarly, the CDF of the random variable X_2 has a function of small x_2 that is nothing but limit x_1 tends to plus infinity of CDF evaluated at the points x_1 comma x_2 ; so, this is valid for 2 dimensional random variable. So, this (Refer Time: 28:11) concept can be extended to n dimensional random variable. That means, suppose I denote capital X as a n dimensional random vector; instead of again and again writing n dimensional random variable, I can write capital X with the CDF capital F ; that means, F also has a n variables. Then we can find the CDF of any one random variable suppose I want j th random variable.

Suppose, I want to find out the CDF of j -th random variable that is nothing but limit x_1 tends to infinity limit x_2 tends to infinity I assume that j is in between 1 to n . Therefore, limit x_{j-1} tends to infinity, limit x_{j+1} tends to infinity and so on, limit x_n tends to infinity of capital F ; which has a elements just I will write down in the next line x_1 comma x_2 x n .

So, this is the way one can get the CDF of 1 dimensional random variable from the CDF of n dimensional random variable, where j can be 1 2 and so on till n . In this exercise, I have not said whether the random variable is of the discrete type or the continuous type or mixed type. So, based on the each random variable or of the discrete continuous or mixed; one can discuss the joint probability mass function or joint probability density

function and so on. So, at present we do not know; what is a type of each random variable.

Therefore, we stopped it at the CDF of the n dimensional random variable. Once we know the type of each random variable, then one can go for studying the probability mass function jointly, probability density function jointly that is going to be the second lecture.
